MDCCLXXII.

CONIC SECTIONS.
CONIC SECTIONS are curves that are formed by the intersection of a cone and a plane. The cone is formed by a circle or ellipse as a base, and a point as a vertex. The plane is a flat surface that intersects the cone. The intersection of the plane and the cone forms a conic section. The conic sections are the circle, the ellipse, the parabola, and the hyperbola. The circle is formed when the plane is perpendicular to the axis of the cone. The ellipse is formed when the plane is inclined to the axis of the cone. The parabola is formed when the plane is parallel to one of the sides of the cone. The hyperbola is formed when the plane is inclined to the axis of the cone, and intersects both nappes of the cone. The conic sections have many important properties, and they are used in many areas of mathematics and science.

CHEMISTRY.
Chemistry is a branch of science that deals with the properties and behavior of matter. It is concerned with the composition, structure, and properties of substances, and with the changes that they undergo. Chemistry is a fundamental science that is essential for understanding the world around us. It is used in many areas of science and industry, and it has led to many important discoveries and inventions. Chemistry is a dynamic field that is constantly evolving, and it is one of the most exciting and challenging sciences to study.

GAL.
GAL is a unit of measurement for the volume of a liquid. It is equal to one-tenth of a liter. The word "gallon" comes from the Old English word "gall", which means "to measure". The gallon is a common unit of measurement in the United States and in the United Kingdom. It is used to measure the volume of liquids, such as water, oil, and milk. The gallon is also used to measure the volume of gases, such as air and hydrogen. The gallon is a convenient unit of measurement for many everyday purposes, and it is an important part of the metric system.

LIGHTING TO MAXIMILIAN

LIGHTING. Man has been engaged in continuous effort to utilize the hours of darkness through the application of artificial illumination. Methods of producing light remained primitive over long periods of time, and, when improved methods were introduced, the use of the earlier forms continued, so that at no time has one method completely replaced another. More than half of the world's inhabitants still have only flame sources for artificial light.

Artificial illumination is obtained as a result of combustion, incandescence or electric discharge with or without fluorescence. Sources of light may be divided into three classes: (1) vegetable and animal fatty substances; (2) carbonaceous matters, gases and oils; and (3) electrical.

Light as a physical phenomenon is discussed in the article **LIGHT**, while its perception is dealt with in **VISION**.

This article is divided into the following sections:

I. Historical Development

1. Oil Lamps
2. Candles
3. Gas
4. Acetylene Gas
5. Pintsch Gas
6. Electric Lamps
7. Electric Discharge Lamps

II. Modern Electrical Light Sources

- A. Arc Lamps
- B. Incandescent Lamps
 1. Losses
 2. Gas-Filled and Vacuum Incandescent Lamps
 3. Mechanical Features
 4. Spectral Quality of the Incandescent Lamp
 5. Other Factors Affecting Light Output
- C. Gaseous Vapour Lamps
 1. Low-Pressure Mercury-Vapour Lamps
 2. High-Pressure Mercury-Vapour Lamps
 3. Other Gaseous-Vapour Discharge Lamps
- D. Fluorescent Lamps
 1. Operation
 2. Characteristics
 3. Economic Consideration

E. Electroluminescence

III. Illuminating Engineering

1. International Organizations
2. Measurement of Light

3. Lighting Environment
4. Light Control
5. Design of Lighting Installation
6. Operation and Maintenance of Lighting Systems

IV. Specific Lighting Applications

1. Residential Lighting
2. Retail-Shop Lighting
3. Office Lighting
4. Industrial Lighting
5. School Lighting
6. Street Lighting
7. Floodlighting

L. HISTORICAL DEVELOPMENT

The earliest form of artificial illumination was the fire used by primitive man for warmth and for protection against wild beasts, and flaming faggots from the campfire were the first torches. From this beginning, thousands of centuries before written history, the torch in various forms has continued as a source of illumination throughout the world.

The flambeau of the middle ages, carried by pedestrians at night, was a torch consisting of twisted fibre coated with some inflammable substance. These torches provided the earliest form of street lighting, being fastened in metal holders to the outside walls of houses. Pieces of resinous wood, stuck between the stones of the fireplace, gave forth bright but smoky flames for lighting the homes of early New England.

Unusual sources of artificial illumination are the glowworms, beetles and fireflies supposedly confined in lanterns in the West Indies or stuck in wax in shallow saucers in Java. Oily carcasses of various animals with wicks drawn through them have been used; the penguin has been most frequently used in this manner.

1. Oil Lamps.—The earliest prehistoric lamp dates to the Mousterian Age. This was a hollowed piece of stone, very crude, found at Le Moustier, France, in 1928. Terra-cotta lamps of 7000–8000 B.C. have been found on the Mesopotamian plains, and Egyptian and Persian copper and bronze lamps of about 2700 B.C. have been discovered at various times.

By 1000 B.C. an advancement in lighting efficiency was provided by a wick of vegetable fibre burning in a saucer-type vessel holding olive or nut oil, and by 500–400 B.C. oil lamps had come

into general domestic use. Roman lamps of unglazed and glazed terra cotta had two or more spouts, and later bronze and iron lamps were introduced, with designs becoming more elaborate. About 100 B.C. the Romans developed the first true lantern of horn, cylindrical in form with a perforated top. Vegetable-oil lamps were in general use among the early Jews, Greeks and Romans.

The first record of mineral-oil lamps was made about A.D. 50 when Pliny the Elder mentioned this use of oil found on the Adriatic shores. Japanese history in A.D. 615 mentions "burning water," and Marco Polo wrote in the 13th century of Baku oil springs furnishing oil satisfactory for lighting purposes.

Early attempts were made to improve the efficiency of oil lamps. About the latter half of the 1st century A.D., Hero of Alexandria devised a lamp in which pressure of brine acting through a column of air raised the oil to the wick. In 1490 Leonardo da Vinci added a cylindrical glass chimney fitted into a glass globe filled with water. The light burned steadily, and through lens action the work surface was brightly lighted for night study. Da Vinci also devised water lenses for correcting near vision, the first recorded analysis of the fact that seeing is a combination of light and vision.

Various types of oil lamps were used through the 14th to 17th centuries, but with little improvement of efficiency. The Betty lamp of the Pilgrims (1620), a metal receptacle with a wick lying in a slot and protruding from one side, was equipped for hanging from mantelpieces or shelves. Fish oil was the chief illuminant.

In 1784 the Swiss physicist Aimé Argand patented a lamp with round burner and tubular wick and a chimney for directing and regulating the flow of air to the flame. An accident led to the discovery that a round glass chimney reduced flickering, and the Argand lamp marked the greatest advancement in artificial illumination to that date. In 1800 Bertrand G. Carcel added a clockwork pump for raising and feeding oil to the wick and, because of the steadiness of the light produced, the Argand lamp in this form became a photometric standard. Benjamin Franklin discovered that two wicks side by side a small distance apart gave more light than two single-wick lamps.

Distilled coal oil produced by James Young in 1850-51 was an improvement, but the discovery of petroleum by Edwin L. Drake in 1859 provided an inexpensive illuminant of high lighting efficiency, and the crude-oil lamp was practically superseded. In the following 20 years an average of 80 patents per year were granted for various types of improved oil lamps. One of the most important was the duplex burner lamp introduced in 1865 by Joseph Hinks. In 1868 the Wells light combined an oil spray with vaporized oil through the use of pressure, giving a highly luminous flame, the principle used in modern flare lamps. The Kitson lamp of 1885 was a pressure-type lamp using platinum mantles, replaced later by Welsbach mantles.

During the latter half of the 19th century oil lamps underwent many changes and improvements intended to make them more attractive for domestic use and more efficient for industrial purposes. They were mounted on elaborate bases and the oil reservoirs were decorated; some were designed for suspension from ceilings and others were portable. The latter designs carried over into the 20th century, and the kerosene lamp with a flat wick in a perforated metallic holder and a plain glass chimney came into extensive use in rural districts.

2. Candles.—The use of candles dates as far back as the beginning of the Christian era, and candlemaking is probably one of the oldest industries of mankind. Among aboriginal races in Africa oily nuts were burned in clay saucers; later they were strung on twigs, thereby providing continuous illumination.

In A.D. 100 Greek and Roman true candles were made of flax threads coated with pitch or wax, although the Phoenicians are credited with the first use of wax candles about A.D. 400. The candle was not in as common use as the oil lamp for several centuries, but returned during the middle ages. Throughout the 16th to 18th centuries and until the discovery of petroleum, candles provided the only method of artificial illumination available to people of average means. Their use has been closely related to religious ceremonies and customs throughout Christian history.

The earliest candles were rush piths dipped in tallow. Later, splinters of wood, also dipped in tallow or beeswax and called kindle lights, were used. Homemade candles of Pilgrim days were of tallow. The whaling industry in the 18th century brought spermaceti into use. The spermaceti candle, because of its clear, steady flame, was used as a standard measure for artificial light, the term "one candle power" being based on the light given by a pure spermaceti candle weighing one-sixth of a pound and burning at the rate of 120 gr. an hour. The isolation of stearine in 1823 and the development of paraffin in the 1850s furnished improved materials for candles.

Candleholders have assumed various forms. The Prickett chandelier introduced in Italy in 1492 was a multiple-spiked holder mounted in groups around a decorative figure on the wall, with mutton-fat candles forced on the spikes. In the 15th century crystal chandeliers with small cups for holding wax candles lighted homes, ballrooms and public gathering places. Of these candles, 120 would have been required to equal the light of one 100-w. electric lamp, and the number required to illuminate a large room produced considerable heat. Candles in elaborate chandeliers were used for illumination of the house of commons in England as late as 1834, and their replacement by gas was strongly opposed by members. With the advent of gas as an illuminant, the use of candles was gradually confined to church ceremonies, decorative domestic purposes and festive occasions.

3. Gas.—Ancient records of Egypt and Persia provide numerous instances of spontaneous discharge of combustible gases from fissures in the earth. Natural gas was employed as an illuminant by the Chinese centuries before the Christian era. The gas was brought to the surface from beds of rock salt 1,500 to 1,600 ft. deep, conveyed through bamboo pipes and used for lighting salt mines and homes in Szechwan province.

In 1664 near Wigan, Lancashire, Eng., John Clayton discovered a pool of natural gas near a coal mine, and later described satisfactory experiments in extracting coal gas by distillation. In 1726 Stephen Hales reported that 158 g. of Newcastle coal would yield 180 cu.in. of "inflammable air," and in 1733 Sir James Lowther sent specimens of distilled coal gas to the Royal society for experimentation.

In 1784 Jean Pierre Minckelers first used gas for lighting. Contemporaneously, in Paris, Philippe Lebon experimented with distillation of gas from various materials for domestic use, and in 1799 Lebon patented a "thermo-lampe," using gas distilled from wood.

The first extensive use of illuminating gas is ascribed to William Murdock, who, in 1792, lighted his home in Redruth, Cornwall, Eng. The gas was produced in large iron retorts and conveyed 70 ft. through metal pipes. In 1798 Murdock installed gaslighting in a factory near Birmingham, Eng., and soon was providing gas commercially for several shops in the vicinity.

The new illuminant was denounced as dangerous and impractical, slowing its adoption. Through the efforts of F. A. Winsor, a German, the first public installation of gaslights was made in London in 1807. For dispelling the public prejudice against illuminating gas, Winsor is referred to as the father of gaslighting. Westminster bridge, London, was illuminated by gas in 1813; Paris adopted gas for street lighting in 1818; and most cities in England and Europe soon had gaslighting systems. The first domestic use of gas in the United States was in 1806, when David Melville, of Newport, R.I., lighted his home and the street directly in front. The first interior commercial use was in the New theatre, Philadelphia, Pa., where gaslights were installed in 1816.

Between 1820 and 1880 many improved burners were developed, the batwing or fishtail type being most commonly used. The Bunsen burner was invented by Robert Wilhelm Bunsen in 1855, and in 1858 William Sugg invented a burner with an incorrodible steatite orifice. Carl Auer von Welsbach experimented for ten years on the Welsbach mantle, and his system of lighting was first exhibited in London in Feb. 1887. By 1900 incandescent gaslighting was firmly established.

The Welsbach mantle consisted of a cylinder woven of sea-island and Egyptian cotton soaked in a solution of 99% thoria and

1% ceria. After various manufacturing processes, the mantle was altered so that it consisted of a metallic-oxide skeleton. In use the mantle was suspended over a Bunsen burner so that the metallic oxides composing the mantle were heated to incandescence, emitting a brilliant greenish light. By using varying combinations of rare earths in solution for impregnating the mantles, different colours of light could be obtained. Welsbach mantles have continued in use with various types of lamps.

4. Acetylene Gas.—Although the existence of this gas had been known since 1836, its manufacture and use as an illuminant was first described by Henri Moissan in 1892. Simultaneously, in the U.S., Thomas L. Willson demonstrated that acetylene gas obtained by immersion of calcium carbide in water produced an intense white light. By 1909, 290 towns in the U.S. were lighted by acetylene gas. Later its use was confined to emergency lighting in remote areas.

5. Pintsch Gas.—Originally developed for lighting railroad cars by Julius Pintsch of Germany, this gas was used in Europe for many years, and was introduced into the U.S. in 1866. By 1910 there were 93 Pintsch gas works in the U.S., Canada and Mexico. It was used extensively on steamships and for light-houses. Similar to Pintsch gas were the numerous bottled gases developed in subsequent years to provide illumination with Welsbach-type mantles in areas where electricity was not available.

By 1911 conversion of gas fixtures for use with electricity had begun, and soon electricity was rapidly replacing gas for general illuminating purposes. In England and Europe, however, gas enjoyed wide use for a number of years longer.

6. Electric Lamps.—In 1650 Otto von Guericke of Magdeburg, Ger., discovered that light was produced by electricity or by electrical excitation. He demonstrated that when a globe of sulfur was rotated rapidly and friction was produced by pressure of the hand during rotation, a luminous glow could be observed. About 1706 the Englishman Francis Hauksbee (Hawksbee) used this discovery, together with a glass globe exhausted by means of a vacuum pump also invented by Guericke, to produce the first electric light. When the globe was rotated at high speed, then rubbed with the hand, it emitted a faint glow of light. In 1802 Sir Humphry Davy demonstrated that strips of platinum or other metals could be heated to incandescence electrically and would give off light for some time. In 1809 he used a battery of 2,000 cells to pass a current through two charcoal sticks four inches apart, producing a brilliant arch-shaped flame, thereafter called the arc lamp.

Throughout the 19th century, development of the arc lamp and the incandescent lamp were parallel. The earliest recorded attempt to make an incandescent lamp was in 1820, when De la Rue enclosed a platinum coil in a piece of evacuated glass tubing. In 1840 Sir William Robert Grove of England lighted an auditorium with feeble, impractical lamps using platinum coils heated to incandescence and covered by inverted tumblers in glass dishes partly filled with water. The cost of the current consumed by the installation was estimated at several hundred pounds a kilowatt-hour.

In 1841 Frederick de Moleyns of Cheltenham, Eng., obtained the first patent granted for an incandescent lamp. His lamp was unique, consisting of an evacuated glass sphere containing powdered charcoal which bridged the gap between two platinum wires or filaments. Light was produced by passage of current through the filaments, heating the charcoal to incandescence. However, the globe blackened quickly and the lamp was short-lived.

In 1845 Thomas Wright of London obtained the first patent for an arc lamp, and in the same year a young Ohio inventor, J. W. Starr, obtained a British patent for two incandescent electric lamps. Edward G. Shepard in 1850 constructed a lamp using incandescent charcoal. The same year Sir Joseph Wilson Swan, English physicist, devised carbon filaments of paper.

During the latter part of the 19th century many scientists tried to produce electrical illumination on a practical commercial basis, and there are records of occasional use of electric lamps throughout the period. In 1856 the French engineer C. de Chagny patented a novel platinum-filament lamp for mines, and in 1857

the first commercial installation of an electric arc lamp was made in the lighthouse at Dungeness, Eng.

In 1872 Alexandre de Lodyguine, a Russian physician, made a lamp having a V-shaped piece of graphite for a filament, operating in a glass globe filled with nitrogen gas. Two hundred of these lamps were installed about the Admiralty dock in St. Petersburg, but unreliability of operation and cost made them impractical for general use. A contemporary, S. A. Kosloff, used multiple rods of graphite operated in nitrogen. None of the foregoing lamps was practical.

In 1876 Paul Jablochkov, a Russian electrical engineer, introduced the Jablochkov candle, marking an epoch in artificial illumination. The Jablochkov candle was an arc lamp having parallel carbon rods separated by porcelain clay, which vaporized during burning of the arc. Alternating current was used to ensure equal rates of consumption of the two points of the rods. This lamp was widely used commercially. First installation of arc lamps for public lighting in the U.S. was in 1879 when the public square in Cleveland, O., was lighted by a system of 12 Brush carbon arc lamps developed by Charles F. Brush.

Before the Edison incandescent carbon-filament lamp was patented in 1880, numerous scientists directed their efforts toward production of a satisfactory incandescent lighting system, outstanding among them being Sir Joseph Wilson Swan. In 1850 Swan had devised carbon filaments of paper; later he used cotton thread treated with sulfuric acid and mounted in glass vacuum bulbs (only possible after 1875). Utilizing this type of lamp, called the electric glow lamp, he gave a large-scale public exhibition of electric lighting at Newcastle, Eng., in Dec. 1878.

Final development of the incandescent lamp was the result of concurrent work by Swan and Thomas A. Edison, using the vacuum pump of Hermann Sprengel and Sir William Crookes. The invention of a completely practical lamp ordinarily is credited to Edison, who began studying the problem in 1877 and within a year and a half had made more than 1,200 experiments. Concurrently, recognizing that the series wiring systems then used for arc lights would not be satisfactory for incandescent lamps, Edison directed much effort toward development of dynamos and other necessary equipment for multiple circuits.

On Oct. 21, 1879, Edison lighted a lamp containing a carbonized thread for the filament. The lamp burned steadily for two days. Later he learned that filaments of carbonized visiting card paper (Bristol board) would give several hundred hours' life. Soon carbonized bamboo was found acceptable and was used as the filament material. Extruded cellulose filaments were introduced by Swan in 1883. The first complete incandescent lighting system was publicly demonstrated at Edison's laboratory in Menlo Park, N.J., on Dec. 21, 1879.

The first commercial installation of Edison's lamp was made in May 1880 on the steamship "Columbia." This installation, consisting of 115 lamps, was operated successfully for 15 years. In 1881 a New York city factory was lighted with Edison's system, and the commercial success of the incandescent lamp was quickly established. More than 150 other installations were made in the following two years. In 1882 the Pearl street generating station in New York city was put into service, and is considered the forerunner of the great central stations subsequently developed. In England an exhibition of electric lighting was held in 1882 at the Crystal palace, and by this time incandescent lamps had been installed in numerous public buildings.

When the incandescent lamp was introduced as a public illuminant, fear was expressed that it might be injurious to the eyesight, particularly when used for long periods by indoor workers. In 1898 the oculists of London petitioned parliament to pass laws against the use of unshaded lights, and consequently research was instituted on various types of shades and reflectors. One of the earliest reflectors used commercially was the one-piece silvered glass reflector developed by E. L. Haines and installed in show windows in Chicago and other cities in the U.S.

Closely related to the incandescent gas mantle, and suggested by it, was the Nernst glower, unique among illuminants of its time as the first practical attempt to substitute some other in-

incandescent substance for carbon filaments. Patented in 1901 by W. H. Nernst of Germany, it utilized a filament composed of oxides of rare-earth elements heated to incandescence by passage of electrical current. Mixtures of two or more oxides were found to be most satisfactory, and in 1905 the commercial Nernst glower consisted of 85% zirconia and 15% yttria. The Nernst lamp did not achieve wide use, but investigations carried out to improve it had considerable effect on the development of the incandescent lamp.

Welsbach invented the first commercial metal-filament lamp, but the osmium employed was extremely rare and expensive. The first applications were in Berlin and Vienna in 1899, but manufacture was discontinued in 1907 when the tungsten lamp appeared. Werner von Bolton, a Russian chemist, discovered the possibility of using tantalum for lamp filaments about 1902, and in 1906 the tantalum lamp was put on the market in the U.S., but it disappeared from use about 1913.

In 1904 Willis R. Whitney of Schenectady, N.Y., produced the heat-treated or metalized carbon-filament lamp, with a higher degree of efficiency than any previous incandescent lamp. But scientists were concerned with the most efficient conversion of electrical energy into light, and the discovery of tungsten as a material for filaments seemed to achieve this goal. The tungsten-filament lamp represented the greatest advance ever made in the quality and efficiency of incandescent lighting, and quickly replaced carbon, tantalum and metalized carbon filaments for commercial use.

The first tungsten-filament lamps, introduced in the U.S. in 1907, made use of pressed tungsten, manufactured by a process perfected by Alexander Just and Franz Hanaman of Vienna. By 1910 William D. Coolidge of Schenectady, N.Y., discovered a process (patented in 1913) for producing drawn tungsten filaments, greatly improving the durability of tungsten lamps.

In 1913 Irving Langmuir of Schenectady, N.Y., developed the use of inert gases inside the incandescent lamp bulb which retard filament evaporation, giving increased efficiency. Nitrogen alone was first used, but later lamps used argon and nitrogen in varying proportions, depending on the wattage. Low first cost, ease of maintenance and adaptability gave the gas-filled lamp such importance in the lighting field that other incandescent lamps practically disappeared. Other significant milestones included dumet seal wire (an iron-nickel alloy) developed in 1913; tipless lamps in 1919; inside-frosted bulbs in 1925; photoflash lamps and the copper-to-glass seal in 1930; and vaporized-aluminum reflector lamps in 1936. A further improvement introduced in 1937 was the coiled-coil type of filament for general service lamps.

Tungsten-filament lamps were developed in a variety of sizes and shapes, for domestic and commercial use and for some highly specialized purposes. By 1935 they were available in shapes varying from the common pear-shaped or round bulb type to tubular forms several feet long. A very small lamp, known as the grain o' wheat lamp, having a bulb only 2 mm. in diameter and 8.7 mm. long, became valuable to the medical profession, providing a light source for internal investigation and surgical work. A lamp smaller than the grain o' wheat lamp was being regularly supplied, and lamps with built-in reflectors were in wide use. Inside silica coatings had improved the diffusing qualities without loss in lamp efficiency.

7. Electric Discharge Lamps.—The observations of Jean Picard in 1675 and Johann Bernoulli about 1700 indicated that light could be produced by agitated mercury. Early research in the field was done about 1850 by Heinrich Geissler, German physicist who invented the Geissler tube, by means of which was demonstrated the phenomenon of luminosity accompanying the discharge of electricity through rarefied gases. An Englishman, John T. Way, demonstrated the first mercury arc in 1860; and John Rapieff of London and the French scientist M. Jamin made further contributions in 1879 and 1882 respectively.

In 1887 Geissler tubes were used largely for laboratory demonstrations, but in 1897 tubes of various colours were used successfully for a display commemorating the diamond jubilee of Queen Victoria of England.

The Moore tube, developed by Daniel McFarlan Moore between 1891 and 1904 along the principle of the Geissler tube, made use of nitrogen to produce a yellow light and of carbon dioxide for a pinkish-white colour approximating daylight. Moore tube lights were most widely used for colour matching, and the first commercial installation was made in a Newark, N.J., store in 1904. The Moore tube was difficult to install and repair, and a complicated valve mechanism was required to maintain the gas at the correct pressure.

The mercury-vapour lamp, originated by L. Arons of Germany in 1892, was not manufactured on a commercial basis. Peter Cooper Hewitt marketed the mercury-arc lamp in 1901, its efficiency proving to be two or three times that of the contemporary incandescent lamp. Its chief limitation was its peculiar colour quality, with light rays concentrated in three restricted spectral regions and with a complete absence of red. Introduction of other gases failed to produce satisfactory results until Hewitt devised a fluorescent screen which converted some of the excess blue and green light and a little of the yellow into red, thereby materially improving the colour. The first practical installation of the Cooper-Hewitt lamp was in the composing room of the *New York Evening Post* in 1903. Creating a nearly shadow-free light and less glare, the lamp immediately found wide use for industrial lighting in the U.S.

Hewitt also developed the quartz tube mercury lamp, used extensively in biological research. A later form of the quartz tube lamp, based on research carried on by C. Bol and others in the laboratories of the Philips company in Eindhoven, Neth., led to exploitation in Europe of a small water-cooled or capillary type of mercury-arc lamp, developed in 1935. Subsequently the U.S. type of this lamp was used primarily for photographic work and for searchlights.

Research in the use of noble gases for illumination purposes was continuous. In 1910 Georges Claude in France experimented with electric discharge tubes containing neon, argon, helium, krypton and xenon, and within a decade the neon sign industry had developed. The novel effects obtainable with neon tubes gave them wide use for advertising purposes, their extreme adaptability, high luminosity and brilliant colours making them particularly suitable in this field. Efficiency of light production by use of neon tubes was too low for general illumination, and none of the colours was satisfactory for interior lighting.

A promising electric discharge lamp developed in Europe by 1931 was the high-intensity sodium-vapour lamp, although it was not satisfactory for commercial or domestic use because of its characteristic yellow colour. Major applications were for highway lighting and general outdoor lighting where colour rendition was not important; and by mid-20th century sodium-vapour lamps were being used for highway lighting and illumination of bridges and vehicular tunnels all over the world.

Fluorescent phenomena had long been known, while fluorescent lamp coatings were investigated in France and Germany in the 1930s. By 1934 the low-voltage fluorescent lamp was under development in the U.S. Offering a highly efficient low-power source in various colours, the fluorescent lamp afforded the nearest approach to "cold" light ever devised in practical form. Fluorescent lamps produce light not by heating a filament to incandescence but by fluorescence of certain chemicals when excited by ultraviolet energy.

The early fluorescent lamp consisted of a low-pressure mercury arc of about 15 w. in a cylindrical glass tube coated inside with mineral salts having fluorescent qualities (phosphors). The efficiency and colour of the light were determined by the vapour pressure and the particular chemicals used. Fluorescent lamps were introduced commercially in 1938, and their rapid application on a large scale marked a major development in the field of artificial illumination. In the following year numerous permanent installations were made, and general lighting by these lamps was completed in two large factories in the U.S. Fluorescent lighting was an integral part of the decorative scheme of the New York and San Francisco world's fairs in 1938 and 1939.

During the ensuing years research designed to improve fluores-

cent sources was carried on extensively, and low- and high-voltage fluorescent lighting found many new applications in interior lighting and luminous decorative design. The adoption of fluorescent lighting was relatively rapid for industrial plants, stores and offices, but not until 1942 was it used to any extent for home lighting, although many specialized applications had been made. In 1944 experimental installations of fluorescent lamps for street lighting were made, and many installations were made in subsequent years. Other developments included rapid-start lamps, which eliminated the disturbing initial flicker; dimming and flashing circuits for special applications; and high-frequency systems which eliminated the need for expensive lamp ballast units. Intensive efforts also were devoted toward increasing lamp efficiency and light output so that the number of lamps needed in a given installation could be reduced.

II. MODERN ELECTRICAL LIGHT SOURCES

A. ARC LAMPS

By mid-20th century the atmospheric arc lamp was used chiefly in large-wattage units for searchlights, for projectors calling for a high intensity and concentrated source, and for other special applications requiring small but powerful sources of blue and ultraviolet energy. The colour of the arc light may be controlled to some extent by use of various materials in the electrodes.

Arc lamps may be classified as: (1) low-intensity arcs, using solid carbon or neutral-cored electrodes and producing light by the incandescence of the electrode; (2) flame arcs, using mineralized carbon electrodes and producing the light from a luminous arc with some incandescence at the electrode ends; and (3) high-intensity arcs, where much of the light comes from the gaseous region immediately in front of the carbon.

When arc lamps operating at atmospheric pressure are operated in parallel, it is necessary to control the flow of current by a ballast or series inductance. Arcs have a negative volt-ampere characteristic and operate at voltages lower than the starting value. Arc lamps must be equipped with automatic mechanisms for starting the arc and adjusting the electrodes. The maximum brightness obtained depends upon the size of the carbons and operation of the arc, and brightnesses exceeding 1,300,000 candles per square inch have been recorded with high-intensity arcs. The carbon-arc lamp operates at an efficiency of from 40 to 65 lumens per watt (l.p.w.). The objectionable noise and unsteady operation of the earlier types were overcome. Special arc electrodes and construction are used for wave-length standard measurements, and the line at the red end of the cadmium arc (6432.5696 Å) has been so accurately measured that the standard of length could be reproduced by using this wave length as a base.

Low-intensity arcs are used for motion-picture projection, photoengraving illumination and other photochemical effects, therapy, ultraviolet irradiation, black-light effects, etc. Uses for the flame arc are related to the spectral characteristics which result from the electrode material used; for example, carbons cored with cerium compounds produce light closely approaching natural sunlight.

High-intensity arcs are widely used for searchlights and large area floodlights and for coloured motion-picture photography and projection. Properly positioned with respect to a large parabolic mirror, the high-intensity arc makes possible searchlights of very narrow beam spreads and intensities exceeding 1,000,000,000 cp.

B. INCANDESCENT LAMPS

Edison developed a 100-w. carbon-filament lamp having an efficiency of 1.6 l.p.w. and a life of 600 hours. This efficiency was sufficient for the early lamp to compete with existing flame sources, but within 50 years manufacturers were offering 100-w. lamps with an efficiency of 16.4 l.p.w. and a life of 750 hours.

1. Losses.—Losses in the incandescent lamp are caused by: (1) heat conduction by lead-in wires and filament supports; (2) heat conducted and convected to the gas of gas-filled lamps; (3) voltage loss in the leads; and (4) light absorption by the glass and the base. After lamps have been in service, the lamp produces less

light because of (1) decreased power consumption as the filament becomes thinner because of tungsten evaporation and (2) bulb blackening. Higher-temperature filaments produce whiter light as well as increased efficiency, and progress has been marked by increased filament temperatures. Drawn tungsten wire, because of its favourable radiating characteristics, low rate of evaporation, high melting point, high tensile strength and ductility, became the preferred material for lamp filaments. This metal is available in sufficient quantity for all lighting needs; filaments for 75,000 40-w. or 1,000 500-w., 115-v. lamps can be made from one pound. No readily available substance exists with the efficiency of tungsten for converting electrical energy into light with no reservations as to cost, manufacturing difficulties or other considerations. The introduction of automatic machines into the manufacture of incandescent lamps aided in the production of a superior, uniform lamp at a nominal cost; and the high quality of the lamp is maintained by rigid specifications and tests.

2. Gas-Filled and Vacuum Incandescent Lamps.—Air is exhausted from the lamps to eliminate oxygen, thereby preventing filament oxidation and vaporization. Air seepage into an incandescent lamp causes rapid deterioration of the filament.

Attempts to introduce inert gases into the carbon lamp for increasing filament temperatures failed because the resultant losses by conduction neutralized filament temperature gains.

The first major improvement of the tungsten lamp was the introduction of an inert gas into the bulb. Nitrogen was first used because the rarer gases were too expensive to obtain; however, by improved processes enough argon became available so that the atmosphere surrounding the filament is composed of 88% argon and 12% nitrogen. Krypton has lower heat conductivity than either nitrogen or argon, but it is too scarce and expensive to be used generally. Because the gas used must be very pure and free from moisture, special care must be taken during lamp manufacture to remove unwanted gases and water vapour.

Higher lamp efficiency can be obtained by increasing the size of the filament because the protective sheath of hot gas is of nearly constant thickness. Coiling the filament made gas-filled lamps practical, and the next step in reducing filament loss was an apparent increase in filament size produced in 1935 by winding the coiled filament around a mandrel. The coiled-coil filament thus formed had an additional 10% to 15% increase in efficiency.

Materials used for lead-ins and supports were improved and the number of supports reduced until end losses from these sources had been reduced to about 2%. Elimination of a support increased the efficiency approximately 0.5%. In the 40-w. lamp, supports were reduced from 11 in the vacuum tungsten lamp to 3 in the gas-filled lamp.

3. Mechanical Features.—The incandescent lamp is an assemblage of a mount, a glass bulb and a base. Standard-voltage lamps of 40 w. or larger contain gas which permits higher filament temperature and thus improved efficiency. The complete mount for a standard large lamp consists of: (1) the stem which carries the molybdenum support wires held in a glass button at the end of the stem; (2) the exhaust tube; (3) the tungsten filament; and (4) lead-in wires. In the press (the sealing point at which the wires pass through the glass) the lead-in wires are made of a nickel-iron core clad in copper, this combination having the same coefficient of expansion as glass; nickel lead-ins are used from the press to the filament, and copper from the press to the base. In some of the larger sizes a mica disk on the stem protects the stem press, stem and socket from the excessive temperature by retarding the circulation of hot gases from the filament when the lamp is burned base up. The base is used for the connection to the electrical circuit. To open the circuit and protect line fuses when the filament arcs, many sizes of lamps have a small fuse just outside the stem press on the mount.

The filaments are supported in many ways for various types of duty. The filament form determines the position in which the lamp may be burned and its resistance to vibration. The filament form also controls the incandescent plane important in projection service. The base of the lamp adapts it to the holder of the equipment, and is cemented except where greater strength and

higher base temperatures require a mechanical base without cement. When the screw lacks carrying capacity in large lamps, it can be replaced by the bipost base which forms a pin-type positive connection and accurate location of the light source. In other cases when precise filament positioning is essential, prefocus bases are used so that lamps may be interchanged in an optical system (e.g., in a film projector) with the filament remaining in the same place. Bayonet, disk and pin bases are used on smaller types and tubular lamps.

Many shapes and sizes of glass bulbs are employed, depending on the wattage and service intended. The bulbs may be clear, coloured, inside-frosted or coated with diffusing or reflecting materials.

4. Spectral Quality of the Incandescent Lamp.—The light emitted from the incandescent lamp is deficient in blue radiation and strong in the red, the exact distribution depending on filament temperature. If additional radiation is desired in the blue region, lamps are operated at voltages higher than normal, resulting in shorter lamp life. The enclosing bulb influences the spectral distribution, the daylight lamp using coloured glass for correcting this region (blue-green glass); this lowers lamp efficiency about 35% because of the light absorbed by the glass.

5. Other Factors Affecting Light Output.—The electrical frequency of the system supplying the incandescent lamp will influence its output. The light from a lamp filament varies as the current decreases from maximum to zero. This is noticeable at the lower frequencies but invisible to the unaided eye for 60-cycle systems. The larger the lamp, the more carry-over there will be. A 40-w. lamp has 13% variation at 60 cycles, while a 500-w. lamp has only 2%, and the same sizes range from 29% to 6% with 25 cycles. Flicker in lighting will be noticed if a 3% change of voltage is applied for a two-cycle duration.

Lamps should be operated at the voltage for which they were designed, though at ordinary rates for electric energy the cost of producing light is often less if lamps are burned at increased voltage. A 10% increase of voltage gives the following results: watts 116%, lumen output 135% and considerably reduced lamp life. A 10% decrease of voltage causes an 85% wattage consumption, gives 71% of lumens and increased lamp life. The selection of rated life for a lamp is determined by a balance between lamp cost, power cost and cost of maintenance and overhead.

As the temperature of the filament was increased, lamp brightness was also increased, so the bulb of the lamp was given special treatment. Early enameling processes were inefficient and increased the collection of dirt. Inside frosting provided reasonable diffusing and reduced the light output less than 1%, compared with 5% to 20% for outside coatings. Later, silica coatings gave excellent diffusion with virtually the same light output as with inside frosting.

A certain amount of blackening inside the bulb is inevitable and is removed in some of the high-intensity short-life lamps by sealing coarse tungsten powder inside the bulb. By shaking the lamp at intervals, the inside of the bulb can be scoured by the tungsten particles, increasing both the light output and useful life of the lamp. In some lamps the vaporized tungsten is removed by passing the hot gases, carrying the vapour from the filament, through a screen above the filament.

C. GASEOUS VAPOUR LAMPS

1. Low-Pressure Mercury-Vapour Lamps.—The Cooper-Hewitt source was the first of the commercial low-pressure lamps. These were built in 200-w. to 1,600-w. sizes using mercury vapour at 1 to 2 mm. pressure and a mercury cathode. The tubes had a rated life of 4,000 hours, but poor colour characteristics. The tube operated on either A.C. or D.C., but auxiliary equipment was required for starting and operating. Few low-pressure Cooper-Hewitt lamps are still in service. An 85-w. Cooper-Hewitt fluorescent lamp which was introduced around 1938 used phosphors on the inner surface of the tubular bulb. Called the R.F. fluorescent lamp, it operated as a full-wave rectifier, giving no stroboscopic effect. R.F. lamps are still being made, but largely for replacement purposes.

Much experimental work has been done in an effort to correct the poor colour quality of the mercury arc. The combination of Cooper-Hewitt tubes with incandescent lamps was an additive method of colour correction. Although this correction did not produce a colour-matching light, it did produce a soft white light which for a time found favour in commercial and industrial fields. For adaption to desired luminaire design, tubes were produced in straight, round and square forms. Pleasing results were obtained with a ratio of 2 w. of incandescent to 1 w. of mercury-vapour light. The development of the fluorescent lamp with its excellent colour and light control possibilities superseded this more complex and expensive means of producing a pleasing colour quality in lighting.

2. High-Pressure Mercury-Vapour Lamps.—The radiation from a mercury arc changes with pressure, and ranges of pressure up to about 280 atm. have been investigated. At high pressures the spectral lines of mercury radiation are no longer sharp but are broadened, giving a background radiation. This broadening is greater toward the red end of the spectrum, which improves colour quality, although it still does not give a balanced spectrum.

One disadvantage of this source is that it requires a starting time ranging from a few seconds for one special 1,000-w. unit to approximately 7 min. for the 400-w. A-H1 type. Any interruption requires a repetition of the starting cycle. Although efficient in itself, mercury lighting is often used in combination with incandescent lighting to ensure continuity of light and to correct the colour of the light source by additive means. The combination should be made on an equal-lumen basis between the high-pressure mercury and incandescent lamps.

3. Other Gaseous-Vapour Discharge Lamps.—In addition to the principal types of discharge lamps there is a subsidiary group of special lamps which includes photochemical, ozone, germicidal, black-light, glow and sunlight lamps, flash tubes and high-voltage neon lamps. The first four are not light sources, strictly speaking, although they do emit some visible light; however, they are produced by light-source manufacturers and are customarily installed by lighting engineers.

Photochemical Lamps.—The characteristic ultraviolet radiation of mercury-vapour discharges is useful for many photochemical processes, such as testing the fastness of dyes and the weathering of paints, water disinfection, photographic reproduction and ultraviolet therapy. Cylindrical mercury-vapour lamps, with walls of quartz or of glass especially compounded to transmit ultraviolet, are manufactured in sizes from 250 to 3,000 w. The quartz types emit energy below 2,800 Å, and the lamps must be shielded from the eyes. Photochemical lamps operate with ballasts similar to those employed with standard mercury-vapour types.

Ozone-Producing Lamps.—These are mercury-vapour lamps that consume 4 w. and operate at 10.5 v. The bulb of the lamp transmits radiation at 1,849 Å, producing ozone which eliminates odours by combining chemically with odorous constituents in the air.

Germicidal Lamps.—The radiation at 2,537 Å produced by this type of low-pressure mercury-vapour lamp is the most effective in producing germicidal action.

Black-Light Lamps.—These emit radiation from 3,200 Å to 4,000 Å, beyond the visible range, that produces fluorescence in certain chemicals (see LUMINESCENCE). The lamps have been used in such divergent applications as advertising displays, theatrical productions, the identification of minerals, crime detection, medical and chemical research, and industrial inspection for quality control. Black-light lamps are available in all sizes in which mercury-vapour lamps radiating ultraviolet are made; however, the radiation from any mercury-vapour lamp can be used if a proper filter eliminates the visible light.

Glow Lamps.—Electrodes sealed in a small bulb filled with neon or argon gas produce lamps that will work on voltages as low as 60 D.C. or 42 A.C. The lamps are used as signal, pilot, indicator and night lights. They have a low current consumption and a life ranging from 3,000 to 25,000 hr.

Sunlight Lamps.—Mercury lamps equipped with special glass bulbs to transmit the middle ultraviolet energy generated by the

TABLE I.—Comparative Data on Light Sources

Source	Candles per sq.in.	Lumens per watt	Luminous efficiency (%)
Sun	923×10^8		16
Candle	3.5	0.1

Tungsten filament, inside frost, 25-w.	22	10.5	1.69

vapour discharge are used to produce sun tan. Various types of mercury sun lamps are available; the most popular for home use is a 275-w. lamp with built-in reflector and self-contained filament ballast for operation on standard 110- to 125-v. A.C. circuits. More powerful sources of erythema-producing ultraviolet are employed for solarium and other specialized applications. Fluorescent sun lamps use phosphors which convert the resonant 2,537-Å energy generated in the arc to longer ultraviolet wave lengths.

Flash Tubes.—Straight or coiled sections of glass or quartz tubing, filled with a noble gas and discharged across capacitors, produce a brief flash of white light for high-speed photography. Xenon is the gas most frequently used. Voltages from 800 to several thousand are accumulated on the capacitors by a D.C. rectifier, and a high-voltage pulse initiates the brilliant flash which produces up to 90,000,000 peak lumens and lasts from $\frac{1}{1,000,000}$ to $\frac{1}{1,000,000}$ sec. For ordinary operation a tube lasts thousands of flashes. The power supply depends on the size of the flash tube; several hundred pounds of equipment are necessary for the larger models, while portable lightweight power packs are available for the smaller flash tubes. With special auxiliary equipment, flash tubes can be flashed repeatedly, some at frequencies up to 30,000 per second. (See STROBOSCOPE.)

High-Voltage Neon Lamps.—The neon lamp is associated with the cold-cathode group, with the luminescence produced by an electrical discharge through gases. These lamps are efficient when of considerable length and contain a high percentage of neon gas, giving the characteristic orange-red colour. To obtain other colours, mercury, argon, carbon dioxide and xenon are used, and coloured glass tubes are used in conjunction with the gases. The voltages range from 8,000 to 12,000 v. The operation of the high-voltage cold-cathode and the high-voltage hot-cathode fluorescent lamp is the same except at the cathodes, where the cold-cathode lamp has the higher voltage loss.

Prior to the introduction of the fluorescent coating, sign tubing had little application for illumination purposes, its low lumen output being used for signs and to create luminous patterns. With mercury vapour and fluorescent coating, and depending on diameter, current rating and length, efficiencies approaching those of standard hot-cathode fluorescent lamps are obtainable. The units are from four to ten feet long and are connected in series to operate from 1,000- to 15,000-v. transformers.

D. FLUORESCENT LAMPS

The fluorescent lamp is a glass tube coated on the inside with a phosphor (fluorescent chemical) and filled with mercury vapour, with a small amount of argon to facilitate starting. After starting the current is carried essentially by the mercury vapour. The design adjustment is such that the desired resonant radiation of mercury at 2,537 Å is produced. Small coils of tungsten wire

(electrodes) are sealed into each end and these filament cathodes are coated with an active electron-emissive material.

The ultraviolet radiated from the conducting mercury gas excites the phosphor, which radiates light in the visible region. Different mixtures of the powders forming the phosphors control the colour of the emitted light. Most lamps are white when unlighted; the gold and red lamps have a pigment coating on the bulb interior to give the desired colours. In the 40-w. fluorescent lamp approximately 1% of the light is delivered directly by the mercury vapour. Of the input wattage 20.5% is converted into visible radiation, nearly three times that from the 40-w. incandescent lamp, which delivers only 7.4% of its wattage in the visible region.

1. Operation.—The operation of the preheat-start fluorescent lamp requires two switches, one for normal on-off switching of the primary power as in the incandescent lamp; and the other for closing the circuit on the cathodes for an instant, allowing the cathodes to preheat, then opening, producing an inductive voltage which causes the arc to strike.

In the typical circuit shown in fig. 1(A), the sockets hold the lamp; the ballast (a coil of wire wound on an iron core) furnishes the inductive "kick" to start the arc and limits the flow of current through the arc; and the filter reduces feedback into the electric supply circuit which may cause radio interference. The starter, wired across the lamp sockets (terminals T_1 and T_2), may be any of three types. The glow switch (fig. 1(B)) consists of a bulb containing neon or argon gas and a bimetallic switch element. When power is applied, the voltage is high across the terminals, and the glowing gas heats the bimetallic switch, closing it; this places the lamp cathodes into the circuit, heating them and reducing the voltage across the glow switch; the switch opens, and the inductive "kick" from the ballast strikes an arc through the lamp. The glow switch remains open while the lamp is in

FIG. 1.—(A) DIAGRAM OF TYPICAL LAMP CIRCUIT; (B) GLOW-SWITCH STARTER; (C) NON-BLINK STARTER; (D) THERMAL-SWITCH STARTER (see TEXT)

operation because the voltage across its terminals is too low to cause a glow.

The non-blink starter (fig. 1[C]) functions in much the same manner as the glow-switch starter except that an additional locking switch is provided; this removes the lamp from the circuit if it fails to function properly after a few attempts at starting. When the lamp is replaced, the starter may be returned to service by pressing the reset button, which protrudes through the end of its case.

The thermal-switch starter (fig. 1[D]) consists of a bimetallic switch, normally closed when power is off. In starting, a small heating element opens this switch after a brief period during which the lamp cathodes heat; the inductive "kick" from the ballast starts the lamp, and the operating current holds the switch open.

Circuits have been designed for the elimination of starter switches, which are always a source of operating trouble. Several standard sizes of hot-cathode fluorescent lamps are available for instant-start service without starters.

The fluorescent lamp has high efficiency, up to 73 l.p.w., but introduces several operating characteristics which necessitate a lighting installation less simple in theory and function than that needed for the incandescent lamp.

2. Characteristics.—Diameter and length of the fluorescent lamp depend upon several factors. Design has been centred about $\frac{3}{8}$ -in., 1-in., $1\frac{1}{2}$ -in. and 2 $\frac{1}{2}$ -in. tubes for the lower voltages; and $\frac{3}{4}$ -in., 1-in. and $1\frac{1}{2}$ -in. tubes for instant starting at higher voltages. Long lamps are more efficient than short ones, other conditions being equal. The fluorescent lamp is more sensitive to surrounding temperature than the incandescent lamp; many sizes of fluorescent lamps generate light most efficiently when the surrounding air is 21° to 27° C. (70° to 80° F.). The lamp voltage divides between the electrode drop (12 to 18 v.) and the voltage gradient, which is the voltage per inch of tube required to neutralize the ions at the walls, plus the conversion of the energy into radiation. For preheated-cathode operation, the open-circuit voltage should be at least twice the lamp voltage. Somewhat higher ratios are required for instant-start lamps.

Early fluorescent lamps, when used singly, often produced an annoying stroboscopic effect because the vapour discharge was extinguished twice during each A.C. cycle. This could be eliminated by using two lamps in the same or adjacent fixtures, with the circuit so arranged that the lamp currents were out of phase. Later, phosphors with longer persistence or afterglow were developed, effectively eliminating the stroboscopic effect.

The fluorescent lamp can be the cause of radio interference caused by direct radiation, radiation from the electric supply or feedback from the line. Proper filtering will minimize the last two causes, while removal of the radio from the field or proper screening will eliminate the first.

Failure of the lamp to function properly may lie within the lamp itself, in the auxiliary or in the starter. The safest rule to follow in correcting the fault is to eliminate by replacement, with spare parts which should be available, in the order of starter, lamp, then ballast; but under no circumstances should the lamp be left in operation if trouble develops.

3. Economic Consideration.—Economic consideration of the fluorescent lamp requires a close study of the cost of both equipment and power. The first cost of fluorescent lamps is relatively high as compared with incandescent lamps of equivalent wattage, but their operating costs are relatively low for a given light output. Replacement of incandescent lamps by fluorescent lamps ordinarily gives two to four times as many lumens per watt.

Since fluorescent lighting systems create less heat they are valuable in conjunction with modern air-conditioning systems and they are also of great usefulness where colour matching or coloured lighting is required.

FIG. 2.—ELECTROLUMINESCENT PANELS

Because of the various ways in which efficiencies may be stated, many claims have been made concerning fluorescent lamps, but it is necessary to include all the losses in the auxiliary with the lamp wattage to arrive at a correct evaluation. Brightness of the fluorescent lamp is much less than that of the incandescent lamp, but it is still so bright that neither the eye nor the work should be directly exposed to it.

E. ELECTROLUMINESCENCE

When fluorescent materials are embedded in the dielectric of a capacitor, one plate of which is transparent, light can be produced by the electrostatic field between the plates. Such sources are called electroluminescent (EL) plates or panels.

The phenomenon was first reported by G. Destriau of France in 1936, but no practical applications appeared until 1950. The fluorescent materials or phosphors are either embedded in an organic dielectric coated on glass or held in a vitreous enamel, ceramic or plastic dielectric coated on a metal plate. The two types of EL devices are shown schematically in fig. 2.

While EL devices are not lamps in the usual sense of the word, they provide means for producing lighted surfaces that are useful in many applications. Surface brightnesses of as much as 10 foot-lamberts (ft.-L.) can be obtained in panels using 600-v., 60-c.p.s. power, and the brightness can be increased to more than 200 ft.-L. with a 3,000-c.p.s. power source. Efficiencies of 10–12 l.p.w. were achieved in early EL panels, but it was thought that efficiencies of the order of 150 l.p.w. ultimately might be obtained.

Electroluminescent panels are used where lighted surfaces of fairly low brightness are required; typical examples are the faces of electric clocks and cover panels for electric switches and outlets. In the case of the organic-type (fig. 2[B]), the rear electrode can be shaped into a desired pattern without visible indication of the electrical connections. Panels of this type have been used for such things as aircraft signs (e.g., "Fasten Seat Belts"), the legends of which are invisible until power is switched on.

In 1959 a new sulfide phosphor was developed which, in a ceramic plate excited by a D.C. power source, emits light only if other energy (light, X-rays or electrons) falls on the plate. The visible image then produced is retained as long as the D.C. field is maintained. Devices using this principle were called image-retaining panels and were used in industrial X-ray testing.

III. ILLUMINATING ENGINEERING

Illuminating engineering is the profession concerned with the application of artificial and natural light. Advancement of the art and science of lighting has been fostered by professional associations, the first of which was founded in the United States (1906), followed by similar organizations in Great Britain (1909), Germany (1913), Japan (1915), Austria and Hungary (1925) and the Netherlands (1926). These organizations and similar groups subsequently formed in other countries embrace all activities connected with the production of artificial light and the design, installation and servicing of lighting systems.

1. International Organizations.—The International Commission on Photometry, founded in 1900, was succeeded by the International Commission on Illumination (I.C.I.) in 1913. World War I halted this reorganization, and the first international meeting of the I.C.I. was not held until 1921 in Paris. The organization's constitution calls for international meetings every three years. Work started by the International Commission on

Photometry, which brought forward the international candle-power standard and solved important problems involving gas lighting, was continued and many other matters of standardization and interchanges of information were implemented by committees representing the leading countries. In 1948 the central bureau of the commission was transferred from Teddington, Eng., to New York city.

2. Measurement of Light.—Light is measured by its capacity to produce a sensation. The eye interprets this sensation in that region of the electromagnetic spectrum which extends from 7,600 Å to 3,800 Å. The eye does not respond equally to the radiant energy in this octave, responding more efficiently to the greens and yellows than to the reds, blues and violets.

There are three units of special importance in the application of lighting in practice: the lumen (unit of luminous flux), the foot-candle (ft.-c.; one lumen incident per square foot) and brightness. Brightness is measured by foot-lamberts for surfaces of low intensity and by candles per square inch for sources of high intensity. In the metric system the corresponding units are the lux (one lumen incident per square metre), and the lambert (one lumen per square centimetre) for brightness. The lumen is used in lighting calculations, while field measurements are made of illumination (ft.-c.) and brightness (ft.-L. or candles per square inch).

Illumination is measured by means of a light meter (foot-candle meter), usually of the photoelectric type.

Measurements of brightness are made with some form of brightness meter which the observer is required to adjust for photometric balance. In the past, average illumination was relied upon to a great extent, but the modern tendency is to give serious consideration to brightness, and future design will continue in this direction.

3. Lighting Environment.—The act of seeing depends upon visual acuity, the size of the object and its brightness, the contrast between object and background, and the length of time the object is exposed for viewing. The first essential to proper vision is that the eyesight be normal or corrected to normal; the second essential is that the proper amount and quality of light be provided.

Period of Exposure.—If the object is large and long periods of time are allowed for exposure, the task can be adequately lighted with little illumination, but for small objects and short exposure periods, the illumination must be correspondingly increased. If the amount of illumination varies, the retina will still retain an image with no consciousness on the part of the observer that the lighting is not continuous if the flicker is rapid. Motion-picture projection bears witness to this fact. However, sudden changes of light at long intervals will cause blurring of moving objects, which becomes more pronounced at low foot-candle levels of illumination. The stroboscopic effect from fluorescent lamps and the flicker noticeable in incandescent lamps connected to 25-cycle sources exemplify the effects of lack of continuity in lighting.

Size of Object.—The size of an object establishes the lighting requirements. By size is meant visual size, which is a combination of dimensions of the smallest detail which must be observed and the distance of the object from the eye. More foot-candles are needed for smaller objects, all other factors being equal. The normal eye can distinguish any object which subtends an angle of one minute of arc. This is an important factor in the design of signs that are to be seen from some distance.

Contrast.—An object is seen more clearly if background and object are of different colours. A white object against a black background can be more readily seen than a black object against a black background. This fact is utilized in industry to obtain contrast between the machine and its moving parts, the material being worked and the surround (visual field).

Brightness.—Brightness contributes directly to the visibility of the object. A very dark object requires more foot-candles for illumination than one with a high reflection factor. For many years foot-candles of illumination were the index to lighting design and specifications, and failure to recognize the importance of the reflection factor led to faulty lighting. More attention is being paid

to the brightness of the task and its surroundings in design.

Glare.—When brightness becomes irritating it is recognized as glare. Glare contributes more to the poor quality of a lighting system than any other factor. Glare may depend upon several conditions present in the lighting system: (1) high brightness of the source; (2) high brightness contrast between the source and the background; (3) location of the source in the field of view; (4) the total volume of the light entering the eye; and (5) the time of exposure to the brightness source. The correction of any one of these contributing factors becomes simple when it is considered individually.

Investigation and experience have established principles for studying the installation in order to control glare. These are not recommended as precise, but are suggestive of order of evaluation: (1) the light output of a source cannot be increased as fast as its area, but it is safe to increase the output as fast as the diameter; (2) increasing the foot-candles ten times in a room permits only doubling the brightness of the light source; (3) doubling the mounting height of a unit allows a lumen output of approximately three times that used previously; (4) brightness ratio of adjacent areas should be within limits of ten to one; (5) there should be more light on the work than at the eye; and (6) each light in a row makes the same contribution to glare. All these specifications are based on equal comfort from the lighting system.

Proper Amount of Lighting.—The severity of the task is the first index to the amount of light required. Lighting may be specified as: (1) For severe and prolonged tasks with details small, contrast low and speed of operation high, 100 ft.-c. or more should be used, best obtained by supplementary lighting. (2) For installations in which speed is not a factor and the object is small, 50 to 100 ft.-c. should be used, and again should be obtained by supplementary lighting. (3) For normal industrial and commercial tasks, 20 to 50 ft.-c. will suffice and may be supplied by a well-designed general lighting system; where economy is a factor supplementary lighting should be used. (4) For most recreational needs and ordinary tasks which are not prolonged throughout the working day, 10 to 20 ft.-c. from a general lighting system is satisfactory. (5) Where seeing is important but not prolonged, the contrast good, the object fairly large and the speed of movement slow, 5 to 10 ft.-c. from a general lighting system is specified. (6) Levels of less than 5 ft.-c. should be specified only for casual and nonhazardous passageways; this is obtainable with a relatively cheap general lighting installation, since for this use the quality of the lighting is of minor importance.

Considering the high foot-candle level to which the eye is accustomed out-of-doors, it is logical to believe that the eye will function best under high foot-candle levels of properly controlled light; that is, light in which quality of distribution approaches that of the out-of-doors. Control of the surround requires a reduction in the foot-candles. The spectral quality of the light source has no influence on seeing, although it does affect the psychological atmosphere; and modern light sources do not emit enough of the harmful wave lengths so that repeated exposures are injurious (this does not hold true, of course, for special lamps such as those emitting ultraviolet). As was the case with the incandescent lamp, the fluorescent lamp when first introduced drew accusations that its light injured the eyes, but any instances of injury or discomfort have been traceable directly to poorly designed lighting systems. Table II compares recommended lighting levels of five countries for various installations.

TABLE II.—Recommended Levels of Illumination for Various Visual Tasks in Different Countries
(in lumens per square foot)

Task or area	France	Great Britain	Sweden	United States	U.S.S.R.	
					Fluorescent	Incandescent
Assembly shop						
Rough work	20	15	30	50	10-15	3-5
Extra fine work	150	150	400	1,000	30-75	15-30
General offices	60	30	30-100	100-150	20-30	7.5-15
School classrooms	50	30	30	70	20	15
Corridors	20	10	8	20	10	3

Colour and Shadow.—Colour and shadow are not necessarily factors in seeing but are of importance in recognition of objects. Colour must be treated carefully when used in conjunction with light. If coloured light is used, white or neutral gray makes the best surround. With the incandescent lamp, usually considered as white light, the spectral distribution of the output must be considered when colours are to be intensified or are to appear in their natural intensity.

Shadows may be either detrimental or helpful, depending upon the task to be performed. For decoration the shadow removes the monotony of a uniform lighting system and adds atmosphere to areas of relaxation, as in the home. In industry the shadow facilitates inspection tasks, emphasizes surfaces in relief and thereby improves visual conditions. Where there is moving machinery or the work lies within a single plane, shadow is detrimental both to safety and visibility. Small concentrated sources will produce harsh, severe shadows, while large area sources of low brightness will produce, for practical purposes, a shadowless surface. Between these two extremes are gradations adaptable to specific types of tasks. Shadow control on stair treads, at corners and on moving machine parts is an important contribution of light to safety.

Surround.—The surfaces surrounding a task area should be properly prepared and illuminated both for light reflection and for psychological effect. Brightness of the surround should be at least 10% of the brightness of the task, although research has shown that, if it is feasible, the task and the surround should be equally bright.

Ceilings should have a reflection factor of 75% or more, and side walls of from 50% to 70%. Any trim occurring higher than 30 in. above the floor may be as dark as desired, provided its area does not constitute more than a small percentage of the total wall surface. The use of warm and cool colours in shades or tints makes little difference if the reflection factors are correct.

Factors Controlling Effectiveness of a Lighting System.—These factors should be considered carefully when analyzing a lighting system: (1) The quantity of light should be such as to produce a desired brightness for the severity of the task. (2) There should be no direct glare from the light source, and the reflected glare should be reduced to a minimum. This can be aided by selection of equipment and work surfaces producing no specular images. (3) Uniformity of the lighting should be controlled. For tasks in one plane, such as writing, drawing and reading, a shadow-free light is desirable. For tasks in three dimensions, such as relief work and inspection, a nonuniform light may be better. (4) Illumination of the surround is essential for the relief of eye strain by providing the proper atmosphere for eye relaxation.

The amount of illumination has been so strongly stressed that frequently quality of lighting is sacrificed by lack of consideration of the elements other than the brightness of the light falling on the task. A lower foot-candle level with proper control is better than a high foot-candle level improperly controlled.

4. Light Control.—Primitive light sources required no shielding, and there was no attempt to control artificial lighting until the 13th century, when mirrors were placed behind the Venetian stand lamp, the *lucerna*. In 1490 Leonardo da Vinci introduced control by refraction, and in 1745 polished metal reflectors were used in the *reverbere*. For the most part, however, control of light belongs to the 20th century.

Classes of Substances.—Transparent materials are not effective with modern light sources because the bare source has a brightness which must be controlled. Transparent material can be used with lighting equipment having very low candle power; however, this class of equipment is more for decorative effect than for lighting, and when used for lighting as well as decoration the quality of light is very poor.

Translucent materials are more widely used than any other light-control substance, and the introduction of plastics into this field in 1933 marked a new stage of light-control development. Translucent glasses of the denser types (opal and alabaster) are used for light backgrounds, while the configured, decorated, structural and architectural glasses are used for decoration where

atmosphere rather than illumination of a task is important. The flashed opal, cased, enameled and light opal glasses have a relatively high transmission and good diffusing qualities. These latter two classes of glass have been widely used in the better grade of lighting glassware and luminous elements.

Opaque materials are used primarily as reflectors and shields. Reflectors for beam control should have a high reflection factor, and usually some form of protected metal film or treated metal is used, silver and aluminum ranking high for this application. For industrial equipment, white enamel and paints on opaque surfaces give high reflection with reasonable maintenance and replacement.

Light-Beam Control.—There are three ways in which the light beam may be controlled: (1) reflection, (2) transmission and (3) refraction. The opaque materials are of the reflection type, and the translucent of the transmission type. Refraction is redirection of light caused by surface shape of the transmitting material. One of the most efficient means of control is by use of prisms, but control in one direction may cause bright spots in others if the arrangement of the prisms is not properly designed.

Nature of the Surface.—Light may be diffused by transmission or reflection from a surface, and diffused light is very acceptable for lighting purposes. Redirected light or even scattered light has its merits in the instance of the special reflector, but may cause specular images or highlights producing objectionable reflected glare. It is recommended that all lighted surfaces within the line of vision (walls and equipment) be of the diffusing type.

Optical Control.—Where accurate control of the light is desired, as in projectors or searchlights, optical reflectors or lenses may be used and for fine control these devices must be accurate. For floodlights and searchlights the control lenses and the reflectors may be made by molding the glass and drawing or spinning the metal. "Sealed-beam" automotive headlights consist of two glass "dishes" sealed together, the rear one silvered to act as a reflector, the front one molded with refracting prisms to concentrate the light in the desired pattern.

Luminaire and Installation.—The design of the lighting equipment and the character of the room are controlling factors in lighting efficiency and light distribution. Lighting equipment is classified into five groups, as shown in Table III.

TABLE III.—Lighting Equipment

Classification	Approximate light distribution	
	% Upward	% Downward
Direct	0-10	90-100
Semidirect	10-40	60-90
General diffusing	40-60	40-60
Semi-indirect	60-90	10-40
Indirect	90-100	0-10

The dimensions of the room and the colour of the ceiling and side walls, as well as the efficiency, depreciation and candle-power distribution of the equipment, control the output. In design the equipment is classified by a coefficient of performance (utilization factor), designating the control in the room of the light from the luminaire, and by the coefficient of utilization, which includes the luminaire efficiency and therefore designates control from the lamp to the work surface. These coefficients may be determined accurately for specific equipment or may be grouped into classes for practical use.

Classification of Outdoor Equipment.—Lighting units for outdoor service are classified as floodlights when the area is not restricted in pattern, and may have broad, medium or narrow beams. The broad-beam equipment is used where the surface to be illuminated is in the immediate area; narrow-beam equipment is used for more distant areas. For a controlled beam the projector or searchlight is used, the first lacking the optical accuracy of the latter. Rotating or fixed equipment used for signal systems is classified as a beacon.

5. Design of Lighting Installation.—There are two methods of lighting design, the point-by-point and the lumen. Each has its specific use, and the accuracy attained with each is satisfactory for practical purposes. The point-by-point method is

used to determine the illumination at a point from a specific lighting equipment for which the distribution curve is known. Where there is no interreflection, the point-by-point method gives the total illumination on the surface at the point; but in an enclosure interreflections will increase the illumination. The point-by-point method is accurate for outdoor lighting, for calculation and design of supplementary lighting and for down lights in interiors. The lumen method is satisfactory for determining the illumination within enclosures and is the procedure accepted in the designing of interior illumination. This is a method of determining average illumination and not specific illumination at a point. Although the method is relatively simple, it considers room proportions, col-

FIG. 3.—POINT-SOURCE ILLUMINATION CALCULATIONS

oration of the room, efficiency of the equipment, type of equipment to be installed and conditions contributing to the depreciation of the lighting system, such as operation and the presence of dirt. The method is based upon empirical data obtained by careful research into the actual performance of lighting systems in controlled installations.

Point-by-Point Method.—This method assumes that for actual conditions the source of light may be considered a point source when the illumination is to be determined on a surface that is at least five diameters from the light source.

The illumination on a point at a distance d from a source (fig. 3) is directly proportional to the intensity of the source and inversely to the square of the distance. This is the illumination on a surface normal to the incident beam of light. When the horizontal or the vertical illumination is desired, the illumination on the normal is corrected by the cosine of the vertical angle for the horizontal and by the sine of the vertical angle for the vertical illumination. Determination of the normal illumination in fig. 3 is given by the formula

$$E_N = \frac{I_\theta}{d^2} \quad (1)$$

and the horizontal illumination therefore is

$$E_H = E_N \cos \theta \quad (2)$$

while the vertical illumination is

$$E_V = E_N \sin \theta \quad (3)$$

Lumen Method.—The general expression for the determination of the necessary lamp size is:

$$\text{lumens per outlet} = \frac{\text{area per outlet} \times \text{foot-candles}}{\text{efficiency} \times \text{utilization factor} \times \text{maintenance factor}} \quad (4)$$

The following steps are necessary in the logical solution of a specific determination:

1. Have a simple but complete sketch of the room to be lighted, with information as to its use, location and dimensions and any special information as to the placing of work surfaces and machines, with the bay dimensions of the ceiling pattern and the nature of any beam structures at the ceiling.

2. Determine the number of units and the spacing of the units. It is good practice to arrange the units symmetrically and to space the units at the corners of squares dividing the room into a symmetrical pattern. Where beams or other obstructions are present the pattern of outlet arrangement should conform to the general ceiling pattern. Outlet spacing should not exceed 1.5 times the mounting height above the work surface for units of the direct, semidirect and general diffusing type; and not more than twice the height of the ceiling above the work surface for the semi-indirect and indirect units. The spacing to the side wall should be approximately one-half the spacing between units. From the layout, with the location of the lamps marked, it is possible to determine the area per outlet.

3. The amount of illumination must be determined for the specific task to be performed. The general requirements previously given will determine in general the foot-candles. To determine the best practice for an installation, reference should be made to the recommendations of engineering societies.

4. Equipment must be chosen for the particular task to be performed. In industrial installations the equipment must usually be relatively inexpensive and easy to clean, and should be of the direct or semidirect type, as the ceiling and walls cannot be expected to reflect much of the light. For commercial installations diffusing types are preferable. In either instance the more successful lighting is obtained where the light source is large and of low brightness. In the indirect system of lighting the ceiling acts as a reflector. Use of luminous elements and cove lighting attains lighting conditions similar to that of indirect lighting. The introduction of the fluorescent lamp, requiring many tubes to obtain the desired foot-candles, gives a light distribution comparable with an indirect lighting installation. The practice of using bare fluorescent lamps without proper light control will produce lighting with distressing glare while indirect lighting will not.

5. The efficiency and the utilization factor (or their product, the coefficient of utilization) must be determined for the type of equipment chosen. The room proportion, room coloration and type of equipment enter into this coefficient. The manufacturer of the equipment can supply this information for the specific equipment chosen, or values may be chosen for the general type, given in widely published tables. Considering a very light ceiling and a fairly light side wall colouring, the utilization factors average approximately 0.5 for direct equipment, 0.3 for semi-indirect equipment and 0.25 for indirect equipment. High coefficients are associated with large and light rooms, and the lower coefficients with small and dark rooms. The over-all efficiency utilization factor of a lighting system is relatively poor.

6. The maintenance factor (one minus depreciation factor) is an estimate of the cleanliness of the location and the maintenance of the lighting system. This factor ranges from 60% in relatively poor conditions to as high as 75% under favourable conditions. Direct equipment will maintain better lighting under the adverse conditions of normal industrial usage than will the semi-indirect or indirect lighting systems, which are generally used for commercial purposes.

Having determined the quantities to substitute, the result given is the number of lumens required per outlet (equation 4). From manufacturer or laboratory data a lamp or a number of lamps may be selected which will most nearly approximate the required lumens. These lamps are rated in watts and should be so specified. Since the lumen output is constantly being changed in the manufacture of lamps, it is desirable to refer to the latest tables of lumen output.

The foregoing is applicable to the design for incandescent installations in which lamps in the larger sizes emit approximately 18 to 20 l.p.w.

Lumen Method and Fluorescent Lighting Design.—The only difference in applying equation (4) to fluorescent lamp installations is that the total area is used instead of the area per outlet, thereby determining the total number of lumens required in the lamp output. After the lamp has been selected, the number required is determined from the output of the individual lamps. Equip-

ment to house the lamps and the arrangement of the lamps is then guided by the number of lamps needed. This design method is not as direct as for the incandescent system, and usually more trials will have to be made to get a satisfactory arrangement.

Design of Luminous Ceilings.—An important development of the 1950s was the introduction of glass and plastic luminous ceilings, either solid or louvered, with lighting sources above them. These simulate artificial skylights and, when properly designed and installed with correct baffling so as not to expose the eye to too large an expanse of lighted surface, represent the best in artificial lighting so far attained.

If a room is large and high, the illumination will be equivalent in value to the brightness of the lighting unit in foot-lamberts. Design of the lighting system embodies design of the light unit as well. The illumination obtained is expressed by:

$$\text{foot-candles} = \frac{\text{total lumens} \times \text{utilization factor} \times \text{maintenance factor}}{\text{total room area}} \quad (5)$$

The efficiency and the utilization factor are determined for a specific design, and the manufacturer has this information available. Spacing does not enter into the problem since the units are placed in the room either from wall to wall or with a border around the unit which is very narrow with respect to the total ceiling dimensions.

Either incandescent or fluorescent lamps may be used as a source to illuminate the ceiling. If the space above the ceiling is deep enough, the largest types of lighting units may be used, even industrial equipment with very large incandescent or fluorescent lamps.

Cove Lighting.—Where the lighting equipment is concealed by coves, with the ceiling and upper wall used as a luminous surface, the system may be designed by the lumen method. Good reflecting equipment will have an efficiency of approximately 70% while the cove itself may show efficiencies ranging from 25% to 40%. Recessed coves and coves close to the ceiling will have utilization factors of 0.35.

Coves placed too close to the ceiling will give an uneven illumination, a ratio of one foot from the ceiling to every five feet of lighted surface being the minimum that should be used. Plaster coves, finished with the wall and ceiling surface, are very inefficient and will give spotty lighting. The use of reflectors increases cove efficiency, and with the correct design the coves can be moved closer to the ceiling. Where control is obtained by use of some form of prismatic lens it is possible to mount the light source against the ceiling. Relief decorations must be crosslighted to eliminate undesirable shadows and produce uniform lighting.

Luminous Architectural Elements.—Luminous elements are applicable both to the exterior and interior of buildings. The term is applied to large, low-brightness lighting sources under which it is correct to consider all forms of indirect lighting as well as architectural elements. The correct application of this type of lighting demands close study, with consideration of the design of the structure as a whole. Luminous elements may take the form of panels, recesses, cavities, niches, pylons, columns, pilasters, parapets, spandrels, soffits, beams, coves, coffers or moldings, or may be incorporated into any architectural design. The light may be controlled by diffusing glass, reflectors, louvers or grillwork or by design of the element shape.

The lumen method is used in the design of the luminous element. Projecting elements have utilization factors of 0.5 and maintenance factors of 0.75, while the flush types have utilization factors of 0.7. Efficiency varies from 10% to 90% depending on the reflection material, the shape and the transmission mediums. In brightness the element should be so proportioned that when it is in direct exposure to the eye it does not exceed 75 ft.-L. If the element is on the ceiling and at such an angle as not to be directly exposed to the eye, a brightness of 500 ft.-L. is allowable. For exteriors the brightness depends upon the illumination of the surroundings and ranges from 30 to 400 ft.-L. on buildings to as high as 600 ft.-L. in letter strokes for signs, on which luminous elements are used extensively.

Glass Blocks.—Used in structures for decorative purposes and lighting, glass blocks may be considered as luminous elements and

must be so designed. The blocks will have transmission values ranging from 10% to 85%. Their obscuring value varies inversely as their efficiency. The transmission of an individual block cannot be considered, as the transmission value of a wall or surface built of glass blocks is largely controlled by the construction. These surfaces may be constructed for both daytime and night use. The lighting equipment must not interfere with light transmission during the day and must be so placed that the rudiments of good lighting are not violated.

It is commonly accepted by the lighting specialist that the providing of illumination is the least successful function performed by windows. Glass blocks allow light to enter but eliminate the normal view from the window. Sunlight falling upon glass blocks will produce a brightness surface which must be controlled, and the removal of a window which can be opened makes it necessary to heat and ventilate the building by some other means. Consideration of glass walls or surfaces exposed to the outside requires careful co-ordination of functional design by the architect and the illuminating engineer.

Floodlighting.—Floodlighting should be designed to produce an effective harmony with the object to be lighted. Daylight effect cannot be reproduced by floodlights, and the effect produced must be studied carefully. The simple straight lines of modern structures are excellent subjects for floodlighting. Statues and monuments should be lighted in collaboration with the artist, while recreational areas and sports fields should be lighted to satisfy the requirements of those participating in the particular sport. Uniform lighting of playing fields often is achieved by aiming each floodlight at a specific point on the playing area, the overlap of the lights eliminating shadow zones.

In locating equipment, the surrounding buildings, topography, area to be lighted and economical aspects of the installation must be considered. If not located directly on the building to be illuminated, the equipment may be located on adjacent buildings, electric service poles, street lighting standards (for buildings not higher than three floors), in shrubbery or trees or on poles installed for the purpose. On the building itself, ledges, cornices and parapets will provide concealment. When sports areas, construction projects and airport loading ramps are lighted it is usually necessary to supply towers, poles or special mounting elements.

For illumination at a distance, narrow-beam equipment is used, ranging from searchlights with optical control to standard narrow-beam (15° or less) equipment. For near areas, broad-beam (30° and over) equipment is used. Intermediate ranges and surface areas may use medium-beam (16° to 29°) equipment. The lumen method of design is used for determination of the average illumination with a standard maintenance factor of 0.7 and the output is determined from the beam lumens of the equipment. Since little if any light can be obtained by interreflection, such light as does not strike the specific area to be illuminated is lost. There must be provision for control of the "spill light" which may become objectionable, and there must be about 10% overlapping of beam pattern so as to attain some degree of uniformity. Tables of recommended foot-candles should be used, and buildings with reflection factors of 20% or less will prove uneconomical to illuminate.

6. Operation and Maintenance of Lighting Systems.—The success of a lighting system depends upon selection of the proper installation and lighting source and upon maintenance. The lighting source should be the most economical, determined from first cost of the equipment, its installation and the power and labour costs in the community where the installation is to be made. Frequently there may be a choice of several schemes and systems which will be adequate and satisfactory as to lighting quality; and no general rule can be applied which definitely determines any combination as superior.

For "seeing," even the monochromatic lights seem to prove equally efficient and comfortable to users. Research has not been able to determine any one source quality which is superior to another for the usual seeing tasks. When colour matching is involved in production, daylight sources of artificial light have proved more satisfactory than natural daylight. No artificial source for ordinary lighting, either incandescent or fluorescent,

radiates wave lengths which under continued usage are harmful to the eyes; neither has it been found that any of these, including daylight sources, has superior qualities for seeing.

Lamp Selection.—The general service lamp, in the voltage rating of the electric system, satisfies the usual conditions. For severe tasks under conditions of vibration, heat, extremes of weather, and unusual position, the type of lamp designed for the particular service should be selected. Special usage lamps vary in their base construction, cementing and filament suspension.

Proper Voltage.—To be efficient, lamps should be operated at their rated voltage. To maintain the voltage at the lamp it is necessary to install adequate wiring systems. The voltage at the lamp, when the system is fully loaded, should not deviate more than 2%. Wiring systems that are inadequate are expensive for reasons of output loss and extra losses in the wiring system. A 120-v. incandescent lamp burned at 115 v. gives only 86.4% of the normal lumen output and will be operating at 92.3% efficiency. The fluorescent lamp is even more critical to voltage change than the incandescent lamp, to the extent of becoming inoperative at incorrect voltages.

Maintenance.—From the first hour that a lighting system begins to operate it deteriorates through darkening of the lamp, dirt accumulation on the lighting equipment and general depreciation of the reflecting surfaces. When this depreciation of the system reduces the initial illumination about 30% it is necessary to consider some form of maintenance. The loss can be partially restored by renewing the darkened lamps, cleaning the equipment and, if these fail, by either washing or painting the reflecting surfaces. A schedule of washing equipment monthly and walls every two years is satisfactory in the average commercial installation. The installation must be designed so that maintenance is possible at low unit costs.

The "smashing point" of lamps, at which it is economical to replace the lamp even though it is still operative, is reached when the lumen output of the lamp has been reduced to the point at which the cost of energy consumed per 1,000,000 lumen-hours exceeds the average cost of light produced up to that time, including initial cost of lamp and energy.

Study has shown that the renovated lighting system could gain 12% by repainting of reflecting surfaces, 20% by cleaning and 19% by using new lamps with proper voltage ratings, a total of 51%. (J. O. K.; C. L. A.)

IV. SPECIFIC LIGHTING APPLICATIONS

World-wide interest in artificial illumination gathered momentum with the beginning of the 20th century. Great expositions held in many parts of the world featured spectacular lighting, using the latest developments. Festivals of light were held in many cities. Widespread interest was shown in the psychological and physiological aspects of higher levels of illumination as related to human welfare, one evidence of this being the adoption in 1937 of a factories act in England containing provisions for compulsory adoption of standards of lighting in all factories and workshops.

Artificial illumination has been accepted as an architectural medium, and lighting is no longer a thing of utility alone, but an intrinsic part of the architectural design of buildings. Specialized types of lighting for various industrial, agricultural and domestic fields have been investigated and adopted.

1. Residential Lighting.—Domestic lighting should be both utilitarian and atmospheric. Light adequate in quantity and quality should be provided for reading, sewing, cooking and cleaning, while its decorative effect enhances the appearance of the rooms.

Most home lighting is inadequate, especially in older buildings. Usually, when an electricity supply first became available, a central ceiling fixture in each room was wired and fitted with a low-wattage lamp. Later, this might be replaced by a more powerful lamp, with some sort of shade added, but progress too often stopped at this point, even in countries where industrial and commercial lighting reached high standards. Many reasons for this have been suggested, including the public's failure to appreciate

the relative cheapness of electric light and the fact that fixtures too often are selected on the basis of their appearance rather than their lighting effectiveness. In addition, inadequate wiring often is an obstacle, for spreading the sources of light about a room is usually better than increasing the wattage at existing outlets.

The various national lighting codes make some illumination recommendations for the home (e.g., from the British code: kitchens, 20 lumens per square foot; casual reading, 15; study and sustained reading, 30), but few householders have either the equipment or the experience to make such measurements. In spite of the dangers of rules of thumb, a recommendation in terms of the electrical loading required to give adequate utilitarian lighting may be more practical: 2 w. per square foot or 20 w. per square metre of floor area (this excludes any lighting for decorative purposes). More light than this is desirable, but it is difficult to achieve adequate illumination with less. For example, a living room measuring 16 by 12 ft. has an area of 192 sq. ft. and thus needs about 400 w.; this could be four 100-w. lamps, two in ceiling or wall fixtures and two in the larger type of table lamp.

In any room the lighting arrangement should take account of the visual tasks to be performed there; a dining room needs direct light on the table, the kitchen requires a good distribution of light sources to avoid shadows on work surfaces, and in the bathroom a light at the mirror is important. In halls, stairways and entries good lighting is essential for safety.

2. Retail-Shop Lighting.—The increasing research on consumer buying habits emphasized the importance of visual impact. An item must be seen if it is to be sold, but seeing is itself a matter of degree, of the intensity of the impression created. The aim of retail-shop lighting is to enhance the appeal of the merchandise.

Display Windows.—The first principle is that the lighting should focus attention on the merchandise, not call attention to itself. This means that the brightness of the light sources must be concealed, and ideally the equipment should be out of sight. The light falling on the display should be considered in terms of quantity, colour, direction and the balance between diffuse illumination and direct beams.

Colour rendering usually is considered to be not so critical in display windows as it is inside the shop. Colour-corrected mercury lamps, usually in combination with an approximately equal wattage of incandescent lamps, have proved acceptable for a wide range of merchandise, and, in high or shallow windows, the better

"INTERNATIONAL LIGHTING REVIEW"

SHOP INTERIOR: INDIRECT LIGHTING FROM 100-W. TUNGSTEN LAMPS AND 40-W. FLUORESCENT TUBES SET BEHIND PANELS ABOVE WALLS; COUNTERS ILLUMINED BY SUSPENDED 150-W. GLASS REFLECTOR LAMPS; SHOWCASES ILLUMINED BY CONCEALED 20-W. FLUORESCENT LAMPS

optical control provided by this relatively small source makes it preferable to the fluorescent tube. More commonly, the fluorescent tube is the choice for general illumination.

Beams of light from different directions differ in their effect. Light from the front, originating as close as possible to the line of view, is the most important in display terms since it illuminates the surfaces facing the onlooker; it is revealing and emphatic. Light from above is normally the easiest to provide, is natural in effect and has the most point when the display presents surfaces at a relatively small angle to the horizontal; beams from the side reveal modeling and texture, but light from below ordinarily gives an unnatural effect. Although screening the source presents problems, light from behind the display can give a sense of depth and three-dimensional reality.

Shop Interiors.—The improved colour-rendering of de luxe fluorescent lamps is more than worth the small sacrifice in efficiency. Lamps with outputs close in spectral distribution to those of incandescent sources are widely used for the display of food, furniture, evening clothes and wherever a luxurious atmosphere is appropriate. De luxe cool white lamps produce a clean, stimulating atmosphere for men's wear, sportswear, white goods, furs, toys, fresh produce, meats and flowers.

In modern merchandising the attempt is made to control the customer's reactions throughout the shop, not merely in the windows; it is light that turns stock into display. Built-in lamps in counters and shelving enhance attention values, while spot-lighting permits controlled emphasis.

3. Office Lighting.—As the pattern of employment in modern society has changed to put the office worker in the majority, the industrial worker in the minority, the office has thus come to represent the typical working environment of the time, and office conditions have increasingly preoccupied those concerned with productivity.

Many factors, such as simplification of building services, have combined to favour large rooms with many occupants. The basic situation facing the lighting engineer is that of a rectangular room with windows along one of the longer sides. Thus, desks are arranged to give a direction of view parallel to the window wall, with the occupants sitting with the source of daylight on their left, since the majority will be right-handed. Fluorescent fixtures in rows parallel to the window wall will produce a light distribution that complements the natural light. Recessed luminaires are often preferred by architects for their contribution to a "clean" interior; many are based on a module common to the standard suspended-ceiling systems.

In private offices, specifications ordinarily call for the same illumination as for the larger general room. However, considerations of prestige are important, and an atmosphere approaching the domestic is often sought.

4. Industrial Lighting.—Experience in the more industrialized countries has shown that modern levels of illumination have proved a good economic investment by increasing productivity, improving quality and reducing accidents. The generally accepted conclusion is that lighting is primarily an environmental factor, with many effects that are beyond analysis. As in the commercial field, management is realizing the overwhelming importance of morale, and the question of how much light workers need is being superseded by another: How much do they want? In those countries where legislation on lighting exists, it is concerned with minimum standards; it is therefore irrelevant to this discussion, for the legally specified levels are far below those of general practice.

For general lighting of industrial interiors the choice of light source is almost always between two types: the fluorescent tube and the colour-corrected mercury lamp. The former has some advantage in terms of efficiency and gives a choice of colour; mercury lamps, on the other hand, provide a powerful light source in a compact fitting, thus simplifying installation and maintenance. Mercury lamps also prove useful as point-by-point replacements for incandescent lamps in the modernization of older installations.

In all but the smallest factories, the penetration of daylight from side windows is inadequate for illumination over most of the floor area, and the electric lighting system is used throughout

the working day. Some processes demand a completely controlled environment, with daylight excluded. The increased efficiency of artificial-light sources has focused attention on the real cost of daylight, which is affected by such factors as the design (and therefore the cost) of the building, heating and maintenance costs, and efficient utilization of interior space. Detailed consideration of these and other economic factors has led to the erection, particularly in the United States, of "no-daylight" factories with flat, opaque roofs; windows, if installed at all, serve a purely psychological purpose.

5. School Lighting.—In England contemporary school architecture puts great stress on generous daylighting. Where buildings are used in the evening as well as during the day, the more extended use of the lighting system is accepted as justifying fluorescent systems for classrooms, but otherwise the assumption may be that the electric lighting will be little used and an incandescent system will be more economical. In practice, artificial lighting is turned on more than calculations based on daylight factors would suggest. As this becomes recognized, fluorescent lighting is increasingly favoured.

In the United States there has been a growing awareness of the role that modern lighting levels and balanced brightnesses can play in producing an efficient and comfortable visual environment. In some localities natural daylight is abundant enough for school illumination.

Lighting in school workshops, laboratories and other rooms for practical or vocational instruction tends to be imitative of the appropriate industrial or commercial environment.

6. Street Lighting.—Safe and fast movement along traffic routes after dark is of major economic importance. Street lighting is a field where some degree of international standardization must be a long-term aim, even though road surfaces—a vital factor—may vary, depending on the locally available materials. However, even national codes have been slow in developing; and where such codes have been published, progress toward applying them fully has often been hampered because public lighting systems are administered by local authorities with limited jurisdiction.

At the levels of illumination usually employed, and from the driver's viewpoint, good colour rendering is unimportant, so the most efficient practicable light source is indicated. At least in

ROTTERDAM, NETH., CENTRAL STATION: GENERAL ILLUMINATION OF PLATFORM IS DERIVED FROM LIGHT REFLECTED FROM CURVED CONCRETE CANOPY

Europe, therefore, the integral sodium lamp has been increasingly used for traffic routes; its size and shape are appropriate for the kind of optical control needed. In the U.S. the colour-improved mercury source has come into favour for many street-lighting services.

On an uncrowded road the driver's perception of vehicles, pedestrians and other objects depends on silhouette vision—on seeing objects dark against the brighter background of the road. Therefore, the lighting engineer's aim is to produce a uniformly bright road surface. When this theory was developed in the 1930s, roads usually had polished surfaces; the most economical solution thus was lights that produced their main beams at angles of only 5° to 10° below the horizontal, and British engineers developed "non-cut-off" lanterns with this characteristic. The opposing view, generally adopted in continental Europe, was that the glare this produced was unacceptable. "Cut-off" lanterns, usually simple metal reflectors, were therefore used at somewhat closer spacings and with the sacrifice of some degree of uniformity in road brightness. However, dramatically increased traffic densities, non-skid road surfaces that require a lower beam angle, and economic progress in general tended toward a compromise between the two views. The trend is to closer spacing and greater mounting heights, and in these conditions semi-cut-off and cut-off designs can produce an acceptably uniform light pattern.

7. Floodlighting.—Almost any type of illumination that permits outdoor work to continue after nightfall can be regarded as floodlighting. In railway yards, quarries and construction sites, high-wattage incandescent or mercury lamps are used in open reflectors or enclosed floodlighting fixtures. However, the decorative lighting of statues, fountains and particularly buildings naturally requires more careful attention.

The classic floodlighting problem is that of achieving an apparently nearly uniform brightness on an extensive vertical surface, using light sources close to its base. Thus luminaires mounted at ground level close to a façade must produce a very high intensity in the direction of the top of the building, for not only is the lighted surface there at a greater distance but the angle of incidence of the light is extreme. Conventional floodlights are designed with paraboloidal reflectors housing projector lamps to produce beams of great concentration. Where necessary, a wider spread can be achieved by using a faceted reflector or an ordinary incandescent lamp, or both. Integral-reflector lamps are sometimes used, especially if the scale is small.

Son et Lumière spectacles are a form of dynamic floodlighting presented to the accompaniment of a recorded sound track of the spoken word and music. The original productions were at the châteaux of the Loire valley in France; others have since been

mounted at the Pyramids, the Acropolis and the Tower of London.

LIGHTNING, any of the various forms of visible discharge of atmospheric electricity. For lightning to occur, there must first be a production of electricity, and a separation in space into centres carrying positive and negative charges, respectively. As the charging proceeds, the electrical field between the charge centres or between the ground and a charge centre increases until a field strength is reached at which the air breaks down electrically. A lightning flash, a large electrical spark in the atmosphere, then follows. Charging processes are usually associated with thunderstorms, sometimes also called electric, or electrical, storms, but somewhat similar though less intense effects are present in blizzards, dust storms and even waterfalls; discharges have been observed accompanying all these phenomena. Much electricity is generated within the clouds produced by volcanic eruptions and nuclear explosions, and copious lightning activity often ensues. (See also THUNDERSTORM.)

I. LIGHTNING AND THUNDER IN FOLKLORE

As one of nature's most awesome spectacles lightning has long challenged man's myth-making ingenuity. Speculations about the great power and destructiveness of lightning have not been limited to primitive man, nor are these notions confined to the great mythologies of the world; they live on in the folklore of every land, with ancient heathen beliefs often persisting side by side with folkloric ideas that emerge mainly from the Judeo-Christian tradition.

Throughout the world, gods have been held to manifest themselves through lightning or thunder. These deities include: Baiame and Daramulum (Australian aborigines); Iko (Maori, New Zealand); Indra and Parjanya (India); Kari (Semang Negrites, Malaya); Kvm (Pygmies, tropical Africa); Wakan (Dakota Indians, North America). In China and southeast Asia dragons are believed to have sacred control of thunderbolts, rain and fertility.

Likewise, the thunderbolt, the mythical bolt or dart that explained the damage done by lightning before the nature of electricity was discovered, was considered the weapon of the etymologically identical gods Zeus and Jupiter in Greek and Roman antiquity, and areas struck by lightning were hedged off as sacred precincts. Persons killed by lightning were not accorded usual funerary rites, but were buried at the spot of the divine fulmination. Thor is the Teutonic counterpart of Zeus, Jupiter and other storm gods of Indo-European mythology (e.g., Perkunas, Baltic; Perun, Slavic; Taranis, Celtic).

In Old Testament times lightning struck fear in the hearts of the people, and was regarded as evidence of the divine will of Yahweh (Jehovah). The idea persists in the classification of death and destruction by lightning as acts of God. That these ideas of divine will extend to primitive peoples is seen among Negroes of the African gold coast, where fires started by lightning are not extinguished, nor aid given a person struck down.

In the Christian community various kinds of sinful and blasphemous acts are said to be punished by lightning. These include perjury, mockery of things holy, desecration of sacred places and utensils, and profanation of the Sabbath and other church holidays.

The hawthorn, laurel, aspen, beech, elder and bay trees, among others, are thought to repel lightning, as are several kinds of bushes, including holly. On the other hand, the poplar, locust and walnut are believed to attract it; likewise the oak and ash as the familiar verse indicates: "Beware of an oak: it draws the stroke; avoid an ash: it courts the flash . . ." German folk verses caution against the oak and fir, and bid one seek safety under the beech during a thunderstorm.

The widespread folk belief in the U.S. that fires started by lightning can be extinguished only by milk is also known in France and Germany. Even though the wood from trees felled by lightning is tabu as a fuel it is nevertheless widely used for curative and magical purposes. Cats and dogs are said to attract lightning, also mules and horses; while pregnant women are considered immune to it, as are sleeping persons and babies in the innocent state before they learn to talk. Such sacred objects as the Bible, candles, bells and salt are held to avert lightning or abate it; for safety the occupants of houses are cautioned to stay away from windows, avoid mirrors and keep well back from the chimney; featherbeds are supposed to offer the surest haven. Quite general is the proverbial and erroneous notion that lightning never strikes twice in the same place.

Various notions have been advanced among the folk of all nations to account for the crash of thunder, such as Thor's hurling his mighty hammer at giants; God's chasing the devil, overtaking and dashing him down; or, among American Indians, the flapping of the wings of great thunderbirds. In more homely U.S. folk idiom, thunder is explained as the "'tater" (potato) wagon trundling down the cellar steps, the angry voice of a displeased God or the noise of his water barrels as they roll across the floor of heaven. Any speaking or other noise made during a peal of thunder is considered a mockery, and is held unfailingly to invite a lightning bolt.

(W. D. HA.)

II. FORMS OF LIGHTNING

The term lightning flash or discharge refers to all the phenomena associated with a single lightning incident. A lightning stroke is a special feature of the flash to earth.

Forked lightning is familiar in a ground discharge; the bright main channel then has less luminous branches directed downwards. Branching results from the inhomogeneity of the electric field encountered by a pilot lightning column, termed a leader, moving from the cloud toward the earth. The leader branches in the directions where the electric field is greatest, thus endeavouring to reach the ground by several paths. One branch usually strikes earth first; the other branches then progress no farther, and the successful branch becomes the main discharge channel. Occasion-

ally branching is slight; this is streak lightning. The accompanying photograph of lightning over Brisbane, Austr., shows examples of both forked and streak lightning. Discharges to earth normally contain several high current surges or return strokes of brilliant luminosity along the same channel. The intervals between strokes vary considerably but 50 milliseconds (1/20 sec.) is typical. This time allows the eye to discriminate between the successive luminous pulses; the effect is seen as the flickering characteristic of many flashes to ground.

Sheet lightning is common. The flash occurs within the thundercloud; the channel cannot be distinguished, only a diffuse illumination over a considerable area is observed. The luminosity fluctuates during the discharge because the distribution of charge in the cloud is not uniform. Sheet lightning usually results from a discharge confined to a single cloud. True cloud-to-cloud flashes are rare.

Many other forms of lightning exist. Heat lightning is the illumination, generally diffuse, observed when flashes are too distant for thunder to be heard. Warm summer evenings favour both the occurrence of thunderstorms and the presence of observers outdoors; the term heat lightning is an understandable consequence of these facts. Air discharges are not uncommon. They often emerge from a cloud and run along the base without reaching the earth. The evidence for flashes upwardly directed from thunderclouds is inconclusive; although currents undoubtedly flow above thunderheads, it is uncertain whether they are spread over a wide area or are confined, as in a true discharge, to a discrete channel. Ribbon and bead lightning are rare forms of the discharge to earth. Ribbon lightning occurs when a lateral wind displaces the successive illuminations of the channel by return strokes; the resulting parallel streaks present a ribbonlike appearance. In bead (or pearl) lightning some parts of the channel appear appreciably brighter than others. This can be because these segments are sections of a zigzag channel viewed end on, but even with a straight channel the luminosity sometimes seems to persist longer in certain parts than in others.

Bead lightning and the most mysterious kind of lightning—ball lightning—may be allied phenomena. Some scientists dispute the reality of ball lightning although there is a core of consistent reports confirming its existence. Very infrequently, under thunder conditions and especially following a nearby flash to ground, a globular luminous mass about 20 cm. in diameter is seen floating in the air. The ball moves irregularly; it usually lasts for a few seconds, and may disappear quietly or with an explosion. Standing electromagnetic waves, ring currents, quantum mechanical exchange forces, and gaseous combustion have all been invoked as causative mechanisms for ball lightning, but there is no entirely satisfactory explanation.

In a ground discharge the channel below the cloud is 1 or 2 km. long and is seldom much inclined to the vertical; within the cloud, the channel is more horizontal than below and the path length increases with the number of strokes in the discharge, perhaps within the limits of 2 to 10 km. Cloud flashes have orientations ranging from predominantly horizontal to predominantly vertical; a typical channel length would be 4 km. Air discharges can be as long as 15 km. There is radar evidence for flashes along a squall line of thunderclouds apparently approaching 100 km. in extent; these discharges may not represent a continuous channel but may rather be a sequence of separated flashes occurring in rapid succession along the squall line. See also SQUALL AND SQUALL LINE.

III. METHODS OF STUDY

Although lightning produces many observable effects it is not an easy phenomenon to examine experimentally. There are two main difficulties: exactly when or where a flash will occur is unpredictable, and the range of magnitudes to be covered is immense. A single discharge may last a second, but the detailed study of certain stages demands a time resolution of at least one microsecond (μ sec.; $1/1,000,000$ sec.); at times the current approaches 100,000 amp., while in other phases of the flash it is less than 100 amp.

BY COURTESY OF S. A. PRENTICE, UNIVERSITY OF QUEENSLAND, BRISBANE, AUSTR.

FORKED AND STREAK LIGHTNING OVER BRISBANE, AUSTR.

Experimental investigations of lightning were initiated by Benjamin Franklin in 1749. Many facts had been established previously by intelligent observations but it remained for Franklin to demonstrate how instructive carefully designed experiments can be. Many of Franklin's deductions remained the best information for more than 150 years, a tribute to the quality of his work (see FRANKLIN, BENJAMIN: *Electrical Science*).

Two techniques of studying lightning have been especially valuable. Photographs of changes in luminosity using cameras that record the variations as a detailed function of time were first obtained by Sir Basil Schonland in South Africa in 1933. This work provided the initial clues to the manner in which a discharge propagates. The second important technique, largely developed by Scottish physicist C. T. R. Wilson (*q.v.*) from 1916 onward, consists in measuring the changes in electric field produced by the flash. From the measurements, the charges and currents involved can be deduced. Close to a discharge, the change in electric field is mainly electrostatic, semipermanent and controlled by the positions of the charges and their magnitudes. Farther away, the field change is dominated by a transient electromagnetic term dependent upon the rate at which the currents change.

Other supplementary techniques are valuable. Current surges in objects struck can be monitored by means of elaborate instruments giving detailed information, installed at points struck frequently, such as the tops of high structures. There are, for example, more than 100 flashes per year to a television mast 300 m. tall located at Champaign, Ill. Unfortunately, however, a discharge to a tall structure differs in character from a flash to open ground. For economic reasons, instruments placed at points struck relatively rarely must be cheap; the resulting information is inevitably limited. Radar reflections from lightning give information on conditions in the channel, while deductions regarding electric charges and currents can be made from the damage to objects that have been struck. Some clues to lightning behaviour emerge from studying long sparks artificially generated in the laboratory. In 1962 this triggering technique was extended to the initiation of natural lightning by firing a rocket trailing a grounded wire toward a thundercloud. An experiment of similar intention was attempted, without proper precautions, by Franklin. Fortunately he failed, but his Russian contemporary G. Richmann was successful both in the experiment and in killing himself.

IV. PROPAGATION OF LIGHTNING

Thunderstorm Electrification.—Thunderstorms normally contain several cells each of which represents a separate electric entity. Individual cells have lifetimes of about 45 min.; they seldom develop simultaneously, one cell generally becomes active as another wanes.

The mechanisms responsible for thunderstorm electricity are complicated. Impact of ice particles and supercooled water droplets upon pellets of soft hail (grape) can produce considerable electrification, especially if, as is usual, temperature differences exist between the impinging bodies. Coalescence of droplets; mass movement of charge by air flow; preferential attachment of ions—air molecules that have either gained or lost an electron and are therefore charged—to precipitation elements; all these are factors contributing to thunderstorm electrification.

In an active thundercloud the larger particles usually possess a negative charge while the smaller carriers are positively charged. The electrical structure can be very complex, but a simple model applies to perhaps half the clouds. In the upper portions the net charge is positive, some 30 coulombs in magnitude, and spread over a diffuse volume centred at a height of about 8 km. (one coulomb = the quantity of electricity produced by a current of one ampere in one second). The body of the thundercloud is electrically neutral, containing a mixture of positive and negative charge carriers, representing roughly 1,000 coulombs aggregate charge of each sign. Toward the cloud base the net charge is negative, again about 30 coulombs in size, centred at a height of 4 km. and occupying a more concentrated volume than the upper positive charge. The electric moment of a cloud is twice the algebraic sum of the products of the individual charge magnitudes

and their respective heights; it is +240 coulomb-km. for the above model. If the moment is destroyed, as by a cloud discharge, it can be regenerated within a few seconds. Large particles fall faster than the small carriers by as much as 8 m. per second (m./sec.). Thus within the body of the cloud re-creation of the moment can proceed at 16 coulomb-km. per second—twice the product of the charge concerned (1,000 coulombs) and the relative fall velocity (8 m./sec.). The potential with respect to earth at the negative charge centre is about $-100,000,000$ v.; at the positive centre it is $+100,000,000$ v.; while the conducting upper atmosphere is at $+300,000$ v. Below the cloud the electric field is therefore negative (the sense to drive an electron toward earth); within the cloud it is positive; above the cloud it is again negative.

Flashing in a single thunderstorm cell starts at one or two per minute, then rises abruptly to a peak of perhaps five discharges a minute; this rate is maintained for only a few minutes. The proportion of flashes going to earth is highly variable among individual storms; the rather obvious association applies that if the storm develops at high levels there are few ground discharges. The proportion of discharges to earth increases with geographic latitude; near the equator less than 10% of all flashes reach the ground, but at latitudes of 55° the figure is 40%. Well over 90% of ground discharges transport negative electricity from the cloud to earth. A record of thunder heard upon a particular day defines a "thunderstorm-day." This statistic is related to lightning incidence since the total number of discharges occurring per square kilometer per thunderstorm-day per annum is approximately 0.25. Some parts of the world have more than 200 thunderstorm-days annually; at other places, thunder is unknown. Since it is believed that 1,800 thunderstorms are active over the world at any one time, the plausible flashing rate of 5 per minute leads to a global estimate of 150 discharges a second.

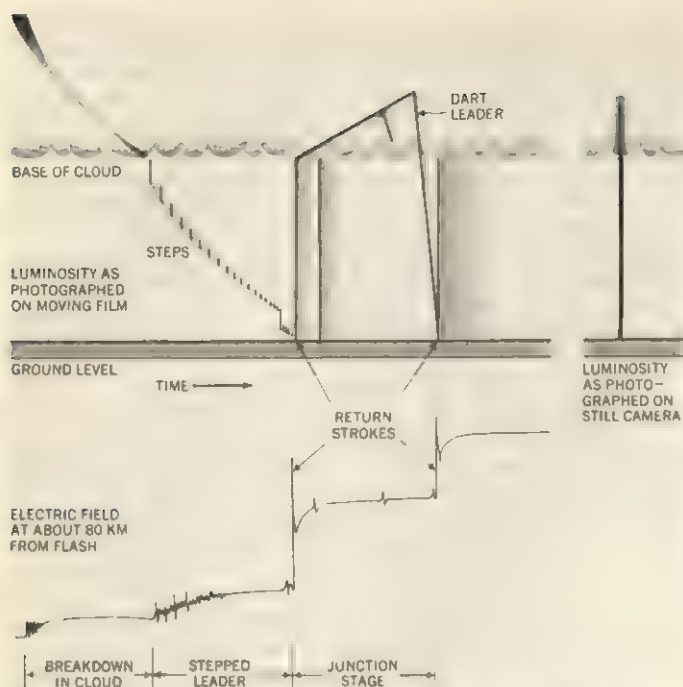

Initiation of a Discharge.—The field strength for electrical breakdown of air at atmospheric pressure is 10,000 volts per centimetre (v./cm.) when water droplets are present. The average pre-discharge field over the path to be bridged by a flash is much smaller, 250 v./cm., for example, between the negative charge centre and the ground. Even within a thundercloud, fields of 1,000 v./cm. are exceeded only over limited areas.

Thus the flash does not take place because the breakdown field strength is simultaneously reached over the whole path. Rather, there is a progression of the breakdown across the gap. In large electric fields water drops distort and show elongated tips. Electrical corona discharge occurs from these tips: a drop disrupts to give a positive streamer spray of ions and droplets, and to leave a residue carrying a negative charge. The residual particles, being larger, fall relative to the positive carriers. A column of negative charge is thus formed; the electric field due to this negative charge exceeds the breakdown value locally at the top of the column; the air at the tip consequently becomes ionized, and therefore electrically conducting, so that the negative column develops into a leader channel—the infant discharge.

Discharge initiation is very localized. It is most likely at the fringes of the negative charge centre. Once a leader channel is a few metres long its further progress becomes easier. The voltage gradient along the channel is less than that in the adjacent air. Therefore the farther the leader travels the greater the potential discontinuity between its tip and the ambient atmosphere; the larger, consequently, the electric field and the easier the production of the ionization to further advance the leader.

Leader channels contain a core a few centimetres in diameter, within which conditions approximate those in an electric arc, the electrical conductivity being large. The core carries a current approaching 100 amp. and is surrounded with space charge generated by lateral corona.

Leaders can develop whenever a sufficient potential discontinuity exists; during thunderstorms, therefore, they frequently originate and travel upward from tall buildings. The field below a thunderstorm is typically 100 v./cm.; the potential discontinuity at a building 300 m. high is therefore 3,000,000 v., more than enough for leader initiation. Tall structures such as the Empire

TYPICAL FLASH TO EARTH: VARIATION WITH TIME OF LUMINOSITY AND ELECTRIC FIELD

State building in New York city are struck more commonly than would be expected; by generating upward leaders they provoke discharges that otherwise would not have occurred so readily.

The Flash to Earth.—The variations with time of the luminosity and electric field associated with a typical ground discharge are represented in the figure. All the phenomena occur within a single channel drawn vertically for simplicity. A still photograph would show only a vertical streak. If, however, a moving film is used, channel development can be followed, and the fact that various sections become bright in turn can be established. The upper part of the figure shows the luminosity changes, and the lower portion the accompanying variations in vertical field at the earth's surface. The field changes are for 80 km. from the flash; at this distance the semipermanent electrostatic field component and the superimposed transient electromagnetic radiations are of comparable size.

Breakdown as a leader process in the cloud is often facilitated by the presence of a small subsidiary positive charge at the cloud base; this charge is generated by corona at the ground and transported upward. The leader, originating and fed from the main negative charge centre, may have to pause in its motion toward earth until the subsidiary positive charge is neutralized. After emerging from the cloud, the leader moves downward at a vertical speed typically of 10^7 cm./sec. Often there is a momentary brightening for about 1μ sec. of perhaps the forward 50 m. of the leader channel. This brightening is repeated at intervals of some 50μ sec., so that the advance of the leader is apparently by steps. In reality, the advance is steady; only the brightening is intermittent. During a step the channel current may increase momentarily to 1,000 amp. In the leader stage the channel, even when the steps are occurring, is never very bright.

The leader reaches the ground about 50 milliseconds after the initial breakdown. As it progresses, negative charge is deposited on and around the channel. This negative charge induces a corresponding positive charge on the earth's surface, and as the leader approaches the ground the fields between the charges increase so that a positive upward leader develops from the earth. Over open terrain, the two leaders unite a few metres above the ground. Following the union, a massive surge of current, representing the mutual charge neutralization, moves up the channel at very great velocity (10^{10} cm./sec.). This spectacular effect is the return stroke. The upward velocity decreases as the return stroke travels higher, because the portions of the channel now

being reached have had time to decrease in conductivity since their original formation. Typically, the current in the return stroke crests to 20,000 amp. in 10μ sec., and causes intense heating and luminosity. Spectroscopic observations show that the temperature reaches $25,000^\circ$ K.; at this temperature the air molecules are dissociated into their constituent atoms, many of which become ionized. Relaxation from the various excited atomic and molecular states causes the brilliant light emission. The diameter of the return stroke channel is only a few millimetres. In the channel the air density is momentarily reduced to perhaps a hundredth of that in the ambient atmosphere; there are approximately 4×10^{17} atoms per cubic centimetre while the electron concentration is 10^{17} per cubic centimetre. Thus the channel is a 25% ionized plasma.

After the return stroke, the current and the associated luminosity in the channel can decrease abruptly or can continue for some time. The channel is now positively charged and positive streamers, known as junction leaders, probe into the cloud in search of untapped concentrations of negative charge. If a concentration is encountered, and the continuing current is still appreciable, a surge of renewed current passes along the whole channel to ground. If, however, the continuing current drops below about 50 amp., the channel decreases appreciably in conductivity; an encounter with a minor centre of negative charge then usually produces a current surge, and an associated recoil streamer of luminosity reaching only part way to the ground. These partial surges produce characteristic variations in electric fields known as K changes.

Sometimes a junction leader taps a negative charge sufficiently intense to cause re-energizing of the entire channel to earth; the recoil streamer is then termed a dart leader. The velocity (2×10^8 cm./sec.) of the dart mechanism is much greater than that for the stepped leader; this is because the channel is still carrying residual ionization and is therefore more conductive than the virgin air first penetrated by the stepped leader process. As with the stepped leader, the dart leader deposits negative charge along the channel, so that when the dart reaches the earth conditions are suitable for a second return stroke to occur. This, and any subsequent stroke, differs from the first in that the upward velocity is constant and the current reaches its peak in less than 1μ sec.

Following a return stroke, the cloud may discharge steadily by a continuous current, intermittently by further strokes, or, as usually happens, by a combination of both mechanisms. About 80% of flashes to earth include more than one stroke, while the average number of strokes in a ground discharge is four. The total change of moment is some 150 coulomb-km., with about 25 coulombs of negative charge flowing to earth, mostly in long continuing currents of low magnitude. The power output in a return stroke exceeds 1,000,000 Mw. (10^{12} watts) for a few microseconds, but the average over the whole duration (typically 300 milliseconds) of a flash is about 4,000,000 kw. (4×10^9 watts). The total energy of the flash is about 350 kw.hr.

Cloud Discharges.—The first lightning in a thunderstorm is within the cloud. As with the ground discharge, the flash originates as a leader; this develops between the two main centres of charge, thereby producing a lightning spark and neutralizing the electrification. A leader in a cloud never encounters a medium, such as the earth, of good electrical conductivity, through which charge can pass very readily. Consequently, the peak current in a cloud discharge rarely exceeds 10,000 amp. Currents of over 1,000 amp. are, however, not infrequent. They occur when the advancing leader, which may be carrying either positive or negative charge, encounters a charge centre of the opposite sign. A readjustment of conditions within the channel follows, and a luminous recoil streamer represents the progress of this readjustment backward from the leader tip. The associated field change and the K change previously discussed are much alike. Indeed there are considerable similarities in the development of a cloud flash and in the processes between the return strokes of a ground discharge. Cloud discharges typically produce a change in electric moment of 100 coulomb-km.

V. EFFECTS OF LIGHTNING

Radio Noise.—The electric field-change far from a discharge is dominated by the transient electromagnetic radiation familiar as the "atmospherics" (atmospheric interference, sferics or noise) that interfere with radio communication. Radio noise extends over a wide range of radio frequencies; it is intense when the current in the discharge changes rapidly. The shorter the path covered by the current, the higher the frequencies radiated. Thus the long channels energized by return strokes radiate predominantly at very low frequencies (3 to 30 kc. per second), while the short sparks that effectively advance a leader give their peak output at perhaps 1,000 kc. per second. In a complete ground discharge the maximum noise signal is at 5 kc. per second; for higher frequencies noise is inversely proportional to frequency. At very low frequencies the noise occurs in pulses and discrimination is easy between cloud and ground discharges; as frequency increases, noise becomes more continuous and it is harder to distinguish cloud from ground flashes. Radio noise propagates in the same manner as conventional radio transmissions.

The "whistler" is an interesting phenomenon. Radio energy emitted by the flash is guided by the earth's magnetic field and may travel far into space. The high frequencies move faster than the low, so the signal after the return to earth can be heard in a loudspeaker as a whistle of descending pitch. Research on whistlers reveals much about the earth's environment in space.

Thunder.—The current surge in a lightning channel produces sudden heating and expansion; this is communicated to the surrounding air as an impulsive compression which, the air being essentially elastic, sets it into oscillation longitudinally, thus generating the sound wave known as thunder. The most abrupt current change, giving the strongest thunder crack, is in the return stroke of the ground discharge. During leader processes currents of hundreds of amperes can flow with little associated light or sound; the current rise is too slow for thunder to occur. At the source, thunder contains a range of sound frequencies extending from about 100 cycles (.1 kc.) per second downward. The higher frequencies are more attenuated during travel, hence the low-pitched rumble of distant thunder. Most of the energy lies in the subaudible frequency range; it often makes houses vibrate and windows and dishes rattle. The thunder wave starts at supersonic velocities but soon slows to 330 m./sec., the speed of sound in air. Since light travels approximately 1,000,000 times faster than sound, the distance of a discharge can be estimated by allowing 330 m. for each second (or roughly 5 sec. per mile) between seeing the flash and hearing the thunder. The lightning channel is of considerable length; thus, the arrival of the sound from the more distant portions occurs appreciably after that for the closest parts and thunder is, consequently, of long duration. Thunder is rarely heard at distances exceeding 15 km. (about 9 mi.).

Lightning-Strikes.—When lightning strikes, several phenomena occur, caused mainly by the current surge of the return stroke. Forces associated with the pinching action of the strong magnetic fields can crush hollow conductors. If the object struck is of high electrical resistance, then large voltages, given by the product of resistance and current (Ohm's law), develop; flashover to nearby surfaces may result. Voltage differences can be transferred great distances if strokes touch metallic conductors such as wire fences. A lightning current surge ending suddenly is described as "cold" lightning; if there is continuing current, the lightning produces heating and ignition and is therefore "hot." Lightning often builds up local pressures by converting water to vapour; destruction of objects sometimes follows.

Lightning tends to strike the highest points. Ships and isolated trees are therefore especially vulnerable. Cold lightning merely damages a tree but the continuing current of hot lightning causes fires. In the United States about one sizable fire results from lightning per 40 sq.km. of forest per annum. Lightning follows the best conducting path; in a tree this is the moist layer below the bark, and bark stripping is consequently a common lightning effect. Traditionally, oaks are struck more often than other trees; this may be correct, but the truly significant factors are height,

habit of growth (in isolation or not) and the proneness to damage, this being dependent on the moisture distribution within the trunk.

Immediate damage to buildings by lightning is small. Heavy currents may pass along wires, and such accessories of civilization as telephones and electrical equipment are therefore particularly vulnerable. The chief dangers are, however, indirect; for example, the starting of fires by quite minor sparks.

Persons struck by lightning are either killed or recover completely, especially if mouth-to-mouth artificial respiration is quickly applied. The lethal current is small and the bodies of many of the victims show no markings; burns are only present for close strokes. Over 70% of casualties occur outdoors, and as countries become more urbanized fatalities due to lightning decrease.

Aircraft in thunderstorms develop a self-charge by colliding with precipitation elements; they also distort existing electrical fields. The fields at the extremities of aircraft can become very high, causing local breakdown of the air visible as a glow discharge (St. Elmo's fire; *q.v.*). Glow discharges generate radio interference that is best minimized by the suitable placing on the aircraft of special discharging points or wicks. Aircraft can provoke lightning strikes by field distortion and also, perhaps, through the exhaust. The current, generally of the continuing type, passes along the fuselage or between wingtips; it follows the longest path in the airplane, this being a better conductor than the surrounding air. Damage is generally slight; minor holes may be burned in the plane's skin, radio antennas may be fused, bearings can be overheated, while radomes covering radar antenna assemblies, being plastic and therefore resistive to current, are especially affected.

VI. LIGHTNING PROTECTION

Statistical information on lightning incidence is essential when considering protection against lightning. It is economically foolish to install a system costing more than the probable losses, but elaborate installations may be justifiable in some situations, for instance in explosives factories.

The principles of protection against direct strokes are simple. A lightning rod, usually of copper, intercepts the stroke before it reaches the threatened structure and passes the current harmlessly to ground. A 45° cone of protection is normally assumed for the rod; this means that it shields over a cone whose radius at the ground is equal to the height of the rod. Upward leaders increase the effective shielding by the rod. The rod is connected to ground through a cable of low electrical resistance (less than 10 ohms); this avoids the development of voltages that may cause side flashover. The lightning current can be adequately carried by a cable only a few millimetres in diameter, but the cable is usually thicker for mechanical strength. All joints must be mechanically and electrically sound, and a good ground connection is often ensured by a counterpoise of buried wires.

The principles of the shielding cone and low resistance path to ground apply to the protection of buildings, trees, ships and power lines. The lightning rod should be mounted as high as possible; for houses this usually means on the mast carrying the television antenna; for ships, the mast is again the appropriate support, and if the hull is nonmetallic, and therefore nonconducting, the ground connection is made to a plate immersed in the water. Power transmission lines usually have one or more grounded overhead wires; each transmission tower has a low footing resistance, the ground connection being improved by buried conductors. With all installations the dangers of flashover, as from adjacent trees, must be considered.

In rural areas voltage transfer can occur along wire fences; these should be grounded at 50 m. intervals and their electrical continuity broken every 200 m. by insulators. Radomes in aircraft are protected by strips of aluminum foil, and bearings are bypassed by metallic "jumpers," thus preventing overheating. Modern aircraft, however, usually avoid storms by flying high and using radar; even within thunderclouds turbulence is a much greater hazard than lightning.

Personal lightning danger is readily minimized. It is best to

be indoors; to avoid contact with the telephone, electrical equipment and water systems; and to sit away from a fireplace. If one is caught outdoors, sheltering in a forest is fairly safe, but isolated trees should be shunned; flashover from the tree can occur and currents can radiate from the trunk along the ground. At the sea or lake, swimmers should leave the water and yachtsmen stay below deck. Proximity to long metallic conductors, such as wire fences, ski lifts and railway lines, is dangerous because of voltage transfer and induced surges. However, during a thunderstorm it is exceptionally safe inside motor cars and railway trains; the metal bodies act as so-called Faraday cages, screening the occupants from the electrical effects. Indeed elaborate protective installations are often essentially Faraday cages made up of interconnected wires.

Even if all direct strokes are avoided, surges induced in long wires, perhaps by flashes to nearby lightning rods, can cause damage. Sometimes, as with the accidental detonation of explosives, this can be catastrophic. Many direct and induced effects can be minimized by using simple lightning arresters in combination with fuses; such devices are often attached to telephone lines, overhead power cables and lead-ins from television antennas before they enter buildings. More elaborate arresters are used on power lines; these consist essentially of a spark gap in series with a nonlinear resistor, and are connected between the power line and ground. A lightning surge in the line breaks down the gap and therefore passes to ground without continuing its potentially destructive course. The nonlinear resistor, by limiting the following current, enables the arrester to reset automatically without the need for circuit breakers. (See *ELECTRIC POWER: Transmission: Transmission Line Design and Construction*.) Electric motors and generators are often protected by suitably connected capacitors; these reduce the rate of voltage rise.

LIGHTNING BUG, the name often given in the United States to the firefly (*q.v.*).

LIGHT VERSE can be defined tautologically as verse written on any light theme. Excluding burlesque and parody, also epigram, limerick, clerihow and macaronics (*qq.v.*), there remains a body of verse in all the western languages almost as great as that devoted to more serious subjects, from which it is divided by no rigid frontier. Light verse is essentially that which celebrates the pleasures of the moment, untroubled by the wingbeat of time the destroyer. It invites to the pleasures of love or of wine; it mocks without malice; or piles up cacophonous mountains of words to deride those who use them for overserious purposes.

Classical.—There are light poems in the *Greek Anthology* (see *ANTHOLOGY*), and both Catullus and Horace wrote light poems which were taken as models by their successors up to the end of the 19th century. Catullus wrote, in *Carmina* ii, of his young mistress's sparrow, in playing with which he hoped to lighten his own cares:

tecum ludere sicut ipsa possem
et tristis animi levare curas.

(Ah, sparrow, could I but play,
Like her, with you
And banish far away
My heart-ache too!)

(trans. by A. S. Way, *Catullus and Tibullus*, Macmillan and Co., Ltd., 1936)

Catullus, however, is never entirely free from these cares. Horace, in *Odes*, i, 20, on the other hand, invites his friends to drink without a thought of the cares they may be drowning at the bottom of the cup:

Vile potabis modicis Sabinum
cantharis, Graeca quod ego ipse testa
conditum levi, datus in theatro
cum tibi plausus,

(There's Sabine for you, when you come this way,
In sober country tankards—nothing grand,
But sealed with my own hand
In a Greek pitcher, on that famous day,
Dear knight Maecenas, when the playhouse rose
To greet you . . .)

(trans. by E. Marsh, *Odes of Horace*, Macmillan and Co., Ltd., 1941)

Sabine, Caecuban and Calenian he can offer, and it is without excuses or self-reproach that he confesses there is neither Falernian nor Formian in his cellar. Seldom could the Romans celebrate the passing minute so cheerfully, since in a world of unbelief nothing could truly comfort a man for the coming of gray hairs and the falling of rose petals.

Medieval.—In medieval Christendom, belief in eternity allowed the poet to watch with less perturbation the fading of that beauty which was his principal theme. The Latin songs of the wandering scholars or goliards (*q.v.*), which attained popularity about the end of the 12th century; the often indecent fabliaux (*q.v.*), rhymed stories chiefly in French, which became current at about the same time; and the mock-epic cycle of the *Roman de Renart* (see *REYNARD THE FOX*), together formed the first great body of light poetry that Europe had known. The goliards may owe something to Horace and the Roman past, though their invitations to drink are coarser and the choice of their wines or beers was no doubt less critical. But the fabliaux and *Renart* are a modern literature, the product of the new middle class. Anti-feudal and anticourtly in tone, they come from that area on the borders of France and Flanders where the wool trade was enriching the new towns. Here for the first time we meet the fox and the crow whose argument over a cheese was told in a more polished way by La Fontaine, some three centuries later. In the 13th-century collection, the *Isopet de Paris*—the title refers to Aesop—the fox lays on his flattery rather thicker; but "Dan Corbel" is as delighted as his more cultivated descendant to hear that he has the finest voice of all the creatures in the district:

Dist Renart: "Par ma foy,
En tout le mont ne say
Nul si belle beste
Comme vous, Dan Corbel
Car fuisse je si bel
Et de cors et de teste!

Il n'est oisel volant
Plus de vous soit plaisant,
Qui vous verroit estendre.
Trop grosse vois avés
Quant haut chanter volés:
Plus n'i a que reprendre."

Side by side with this poetry grew a repertory of vernacular songs, typical of which is the French "Pourquoi me bat mon mari?" which no sooner asks this question than it proposes the remedy:

Or sai bien que je ferai
Et comment m'an vengeraï:
Avec mon amin geirai
Nuette.

("I know how to take my vengeance," she says,
"I'll spend a night with my lover.")

The descendants of such songs are still sung in Parisian revues. The English "Little Pretty Mopsy" is equally frank and commonsensical, and just as up-to-date. The lover knows that kisses are hard to buy, so he asks for them free:

now I se well that kyssys ar dere,
and, yf I shold labvr all the hole yere,
I thynke I shold be neuer the nere;
wherefore, I pray yow, cum kyss me.

One of the finest collections of light verse of many kinds in any language is the *Libro de buen amor* (1343) of the Spanish arch-priest of Hita, Juan Ruiz, which contains the whole repertory of a strolling entertainer, loosely strung together on a thread of pre-

tended autobiography. Here are fables, love songs, serious and burlesque, a battle between Carnival and Lent, satires against the clerics, a song in praise of small women, and several in praise of the Virgin, also other stock religious items. This masterpiece of 13th-century literature contains, in addition, one of the first major literary comic characters, the pander Trotaconventos, who is the mother of the title character of *La Celestina* (q.v.), and the ancestress of Shakespeare's Falstaff, Mistress Quickly and Juliet's nurse. The *Libro de buen amor* derives its material from the goliards, from the fabliaux, from Arabic writing and from popular poetry, and upon all this is impressed the cheerful cast of mind of a worldly, scabrous, curiously learned priest, who could celebrate the pleasures of the world without fear or foreboding since his ultimate trust was in a faith that must redeem him if he believed. Hence his frank rejoicing in the charms of little women, whom he found cold without, yet ardent when in love; comfortable, jolly, cheerful and gay in bed; sensible, pleasing, peaceful and virtuous in the home; and endowed with many other virtues which his hearers would soon discover if they attended to the task. Like the archpriest, Chaucer too takes over the legacy of the *Isopet* in the *Nun's Priest's Tale* and of the fabliaux in the *Reeve's Tale* and the *Miller's Tale*.

Renaissance.—The medieval contribution to light verse was mainly in the realm of the story, satirical, bawdy and irreverent, yet fundamentally sensible and moral. The light verse of the Renaissance tends to revive the pagan conventions of Catullus and Horace. John Skelton in his *Book of Philip Sparrow* takes up Catullus' own theme, in his lighthearted mourning for the death of the girl Joanna's sparrow. Skelton's mock-heroics, however, are still medieval in form, and his *Tuning of Elinor Rummung*, a splendid piece of barroom bawdry, is the greatest fabliau in English. He is a Renaissance figure only in his use and comic misuse of learning, in which he is the English counterpart of François Rabelais. He is perhaps happiest in the fantastic invention of Philip Sparrow's funeral service:

The owl, that is so foul,
Must help us to howl;
The heron so gaunt,
And the cormorant,
With the pheasant,
And the gagging gant,
And the churlish chough;
The knot and the ruff;
The barnacle, the buzzard,
With the mild mallard;
The divendop to sleep;
The waterhen to weep;

and so on through a long catalogue of birds, each with a part to play in the procession. A similar love of lists and strange learning informs the two *Testaments* of François Villon.

French light poetry of the 14th and 15th centuries was written largely in ballades and rondeaux (q.v.), strict forms which challenged the poets to displays of great virtuosity but which limited originality of thought. The prevailing mood was a light melancholy. With Clément Marot a little Horatian wit was injected into these moribund forms. His epigrams, in particular, are pointed in a classical manner that was to prevail for more than two centuries. "De l'Abbé et de son valet" (lxxiv), indeed, well translated, might easily pass as written by the 18th-century poet Matthew Prior:

Monsieur l'abbé et monsieur son valet
Sont faits égaux, tous doux comme de cire;
L'un est grand fou, l'autre petit follet;
L'un veut railler, l'autre gaudir et rire;
L'un boit du bon; l'autre ne boit du pire.
Mais un débat au soir entr'eux s'émeut:
Car maître abbé toute la nuit ne veut
Être sans vin, que sans secours ne meure,
Et son valet jamais dormir ne peut
Tandis qu'au pot une goutte en demeure.

("The abbé and his servant are alike in every way. One's a big fool, the other is a little one, and if one has to drink all night, the other will not go to bed while there is a drop left in the house.")

Ronsard also wrote lightly at times, though his prevailing con-

cern with the passing of beauty cast a shadow even on his gayest lines. He can cry for wine as persuasively as Horace in the verses to his lackey; and he is more particular than Marot in his demands that his bottle be cooled, that he may sit under an arbour, and lie on a bed of flowers when he has finished drinking.

Corydon, marche devant,
Sçache où le bon vin se vend:
Fais refreschir ma bouteille,
Cherche une fueilleuse treille
Et des fleurs pour me coucher.

But he ends his poem with the fear that one day sickness will tell him, in words that carry an echo of Anacreon: "Die, my lad, you've lived too long." (*Meurs, galland, c'est trop vescu.*)

A similar vein runs through the poetry of the English Renaissance from Sir Thomas Wyatt to such Jacobean as Richard Lovelace and Sir John Suckling. Few except Robert Herrick and Ben Jonson were capable of a lightness unmixed with melancholy or sorrow, and these few compensated themselves by writing many heavyhearted poems for each one that was gay. Nevertheless Jonson, in "Inviting a Friend to Supper," promises that

No simple word
That shall be utter'd at our mirthful board
Shall make us sad next morning: or affright
The liberty, that we'll enjoy to-night.

And Herrick tempts his friend, Sir Clipsebie Crew, the recipient of his ode of invitation, with a description of a parson's life in Devonshire that is every bit as carefree and classical:

Then cause we *Horace* to be read,
Which sung, or sey'd,
A Goblet to the brim
Of Lyrick wine, both swell'd and crown'd
A Round
We quaffe to him.

When Herrick is gay he celebrates food, flowers and pretty girls in the cheerful assurance that his "Larres," or household gods, will save from the passage of time anything that he can enshrine in a poem. Suckling, too, in his "Ballad Upon a Wedding," can write of a girl as if she will never grow old:

Her lips were red, and one was thin,
Compar'd to that was next her chin:
(Some bee had stung it newly.)
But (Dick) her eyes so guard her face;
I durst no more upon them gaze
Than on the Sun in July.

Late 17th and 18th Centuries.—At the 17th century progressed, light poetry became more intellectual. Nonsense and other forms of wordplay, the counterpart of the metaphysical conceit, often gave a sinister undertone to words that appear at first to have been chosen out of pure fantasy. Théophile de Viau's nonsense ode, "Un corbeau devant moi croasse," seems to offer a crazy premonition of the end of the world; and even "A Non-Sequitur," probably by Richard Corbett, is not entirely jovial.

The putrid skies
Eat mulsacke pies
Backed up in logick breeches

is crazy enough. But the lines that follow become increasingly baleful:

Munday trenchers make good hay,
The lobster wears no dagger;
Meal-mouth'd shee-peacocks powle the starres,
And make the lowbell stagger.

Samuel Butler's *Hudibras* (1663) is light and digressive in the manner of the fabliaux, and La Fontaine's *Contes* look back in their choice of language and broad anecdote to Marot and Rabelais, but the light form is used to greatest effect in La Fontaine's *Fables* (1668, 1678). Here, without apparent seriousness, a whole picture of society is created, and the behaviour of men anatomized under cover of a delicate fable based on Aesop or drawn from India. Similarly, in the greatest light poem of the 18th century, *The Rape of the Lock* (1714), Alexander Pope builds the most trivial anecdote into a mock epic in which the polite society of

his day is shown by innuendo to be a mere shadow of the heroic days of old. It is in the vein of parody that he asks his initial question:

Say what strange motive, Goddess! could compel
A well-bred lord t'assault a gentle belle?
Oh, say what stranger cause, yet unexplored,
Could make a gentle belle reject a lord?

Among English 18th-century poets Matthew Prior makes fresh use of the broad anecdote, Oliver Goldsmith writes with something of Pope's wit and William Cowper, in his *Diverting History of John Gilpin* (1782), invents the punning narrative that was to be the stock in trade of Thomas Hood.

19th and 20th Centuries.—The greatest English light poem of the 19th century is undoubtedly Byron's *Don Juan* (1819–24), the first important novel in verse, which marked a return to the colloquialism of medieval light poetry. Before him George Crabbe, and after him W. M. Praed, Arthur Clough and, at times, Robert Browning, wrote light poetry that was conversational and digressive in tone. For a while the novel seemed to be leading and the poem following, as it did also in the Russia of Aleksandr Pushkin and his successors. Byron's lightness is sardonic and casual. He throws away a romantic situation with nonchalance:

Alas! for Juan and Haidée! they were
So loving and so lovely—till then never,
Excepting our first parents, such a pair
Had run the risk of being damn'd for ever;
And Haidée, being devout as well as fair
Had, doubtless, heard about the Stygian river,
And hell and purgatory—but forgot
Just in the very crisis she should not.

Clough in the same way, in *Amours de Voyage* (1862), though with rather more show of conscience, writes off Rome and the battle for Italian independence with a colloquial shrug:

Dulce it is, and decorum, no doubt, for the country to fall,—to
Offer one's blood an oblation to Freedom, and die for the Cause; yet
Still, individual culture is also something, and no man
Finds quite distinct the assurance that he of all others is called on. . . .

The 19th century was prolific of light poetry. The nonsense of Edward Lear, the parodies and nonsense of Lewis Carroll, the parodies and occasional verse of C. S. Calverley and the *Bab Ballads* (1869) of W. S. Gilbert are the principal English collections, for which there is little parallel abroad, except for the sardonic doggerel of the German Wilhelm Busch. The cause of this flowering lies in a certain matter-of-fact revulsion from the romanticism of the serious poets, and in the proliferation of humorous periodicals in which such verse could appear.

Light poetry of the 20th century has been sparser and on the whole more literary in its allusions than the punning or the colloquial output of the Victorians. A revival of the 14th-century ballade by Hilaire Belloc, G. K. Chesterton and Sir John Squire, the vogue of the limerick (*q.v.*) and the invention of the clerihew (*q.v.*) were the chief landmarks up to 1925.

American light verse of the 19th century had a parodic character which comes out to perfection in *Hans Breitmann's Ballads* (1871) by Charles G. Leland. These gave a new twist to the macaronic joke, which was particularly apposite to a country so many of whose inhabitants had learned the language in middle life. Earlier American practitioners had exploited the humour of Negro dialect and backwoods jargon. The *New Yorker* school marks the beginnings of sophisticated and urban light verse. T. S. Eliot, in such mock-romantic parodies as "Burbank with a Baedeker: Bleistein With a Cigar," was a forerunner, but the naïve *sotto voce* of *archy and mehitabel* (1927) by Don Marquis strikes a more typically American note. The inventor of this offbeat *vers de société* was Ogden Nash, a master both of the short quatrain and of the longer poem of resigned self-depreciation of the type of "Ask Daddy, he won't know." Nash was the most original and best known of the *New Yorker* poets. Phyllis McGinley, however, produced feminine and more sentimental variants on Nash's self-ironic theme of adult helplessness, and Morris Bishop applied to similar subjects a more traditional talent which at times recalls that of Thomas Hood.

In England the new grotesques of Robert Graves and the neo-Victorian topical verse of John Betjeman were the principal light poetry of the later '50s and early '60s. In France some nonsense of a surrealist kind and in the German-speaking countries the whimsical and punning wit of Christian Morgenstern and the light satires of Erich Kästner stand out among the far thinner output of 20th-century Europe.

Roberts (1942); *The Penguin Book of Comic and Curious Verse* (1952), *More Comic and Curious Verse* (1956), *Yet More Comic and Curious Verse* (1959), all ed. by J. M. Cohen. (Jo. M. C.)

LIGHT-YEAR, an astronomical unit of length, the distance traveled by light in the course of one year, being equivalent to about six million million (6×10^{12}) miles. The distance of stars may be measured in terms of this unit or in terms of the parsec (*q.v.*), which is about 3.26 light-years.

LIGNE, CHARLES JOSEPH, PRINCE DE (1735–1814), officer in the Austrian army, man of the world and, in Belgian literature, the outstanding representative of the elegant sensibility of the *ancien régime*, was born in Brussels, capital of the Austrian Netherlands, on May 23, 1735, the son of Claude Lamoral, prince de Ligne, head of a family long established in Hainaut and ranking as princes of the Holy Roman empire from 1601. Charles Joseph had a passion for soldiering from his earliest years and fought for Austria during the Seven Years' War. When he was chosen to announce the victory of Maxen (1759) to Louis XV of France, his handsome figure and wit won instant favour at Versailles. Having succeeded to immense wealth on his father's death (1766), he could pass his life between Vienna, Versailles and his château of Beloeil, near Mons, one of the great houses of Europe, where he laid out gardens and staged prodigious fetes. His marriage (1755) to Franziska of Liechtenstein had never deterred him from lighthearted amours; he was a favourite of Marie Antoinette; he was welcomed in the Parisian salons; and he visited Voltaire and corresponded with Jean Jacques Rousseau. Throughout these years, however, he remained a trusted adviser of the emperor Joseph II. Sent by Joseph to Catherine II the Great of Russia in 1780, he won her friendship and returned loaded with honours and presents. In 1786 he was once more sent to St. Petersburg, whence Catherine took him in 1787 on her tour of the Crimea. On the outbreak of the Russo-Turkish War he served at the siege of Ochakov (1788) before rejoining the Austrians for the siege of Belgrade (1789).

The Belgian troubles of 1789, the death of Joseph II (1790) and the outbreak of the French Revolutionary Wars (1792) put an end to the happy era of the prince's life. A refugee in Vienna or a guest in other people's houses, he could only write his memoirs and watch, with a soldier's eye, the campaigns of Napoleon I and the mistakes of the allies. His Austrian rank of field marshal (1808) had no practical effect. Yet when the congress of Vienna opened in Oct. 1814, its members crowded about the aged prince to do him honour; and his death, on Dec. 13, was followed by a military funeral which all the congress attended.

The prince de Ligne's *Mélanges militaires, littéraires et sentimentaux* fill 34 volumes (1795–1811), but his personality is best expressed in his letters (collections published in 1809 and in 1812) and in the *Fragments de l'histoire de ma vie* (first printed in 1927). The letters have the easy formality of an 18th-century prince and provide vivid descriptions of incidents in his life; and the *Fragments* are written in a vigorous conversational style anticipating that of Stendhal. There are editions by F. Leuridant of *Oeuvres du prince de Ligne* (1914) and of *Oeuvres inédites* (1914–22), as well as selections in English by K. P. Wormeley (1899) and by L. Ashton (1927).

See F. Leuridant (ed.), *Annales Prince de Ligne*, 19 vol. (1920–38).

LIGNITE. In North America, coals having a moist mineral-matter-free heat content of less than 8,300 B.T.U. per pound are called lignite. Moisture content (as received) varies from 20% up to 60%. The classifications of other countries are overlapping. Some European lignite would be classified "subbituminous" in the U.S. Most brown coals in Europe would be classified as lignite.

Lignite is generally younger geologically than higher-rank coal.

Approximately 4,000,000 tons of lignite are mined annually in the United States, largely by open-pit methods. North Dakota and Texas are the largest producers. Assured U.S. reserves total more than 463,000,000,000 tons, about 15% of the nation's total solid fuels reserves on a B.T.U. basis. About 95% of total tonnage is located in North Dakota, South Dakota and Montana.

The fuel is used by local utility, industrial and domestic consumers fairly close to the mine site. It is adaptable to firing in stokers of the overfeed type, in pulverizers and in cyclone furnaces. It can be shipped and stored in the same manner as higher-rank coals. Because of its greater liability to oxidation and to spontaneous combustion, it requires more careful compaction in stockpiles than coals of higher rank. Crushed lignite can be stored for periods of two or three months without compaction when treated with small quantities of oil.

Lignite (brown coal) resources are a major factor in the development of eastern and southeastern Europe. About one-third of the output is briquetted for domestic and industrial heating. Another one-third is used for power generation. The remainder is used by chemical and carbonization processes. See also COAL AND COAL MINING. (W. A. McC.)

LIGONIER, JOHN (JEAN LOUIS) **LIGONIER**, 1ST EARL (1680–1770), British soldier who was military adviser to the elder Pitt during the Seven Years' War. He was born at Castres in Languedoc, France, on Nov. 7 (new style; Oct. 28, old style), 1680, and came from a French Huguenot family that sought refuge in England in 1698. He joined the British army, took part in all Marlborough's campaigns and battles between 1702 and 1711, and spent the last years of the War of the Spanish Succession as lieutenant governor of Fort St. Philip, Minorca. Later he distinguished himself at the capture of Vigo (1719). In 1720 he was appointed colonel of the Black Horse (7th Dragoon guards). During the War of the Austrian Succession Ligonier acted first as staff officer to George II. He was second-in-command of the cavalry at the battle of Dettingen and was given the Order of the Bath on the field by the king in person. After the battle of Fontenoy (1745) he became commander of the British contingent in Flanders. He led the British forces at Roucoux (1746) and also at Lauffeld (1747), where he saved the allied army from destruction by a brilliant charge of the British cavalry. Soon after the opening (1756) of the Seven Years' War he was appointed commander in chief and acted as military adviser to Pitt; the brilliant successes attending British arms throughout the war worthily crowned Ligonier's lifework. He became a field marshal and was created earl in 1766. He died in Surrey on April 28, 1770, and was buried in Westminster Abbey.

See R. Whitworth, *Field Marshal Lord Ligonier* (1958).

(E. W. SH.)

LIGUORI, SAINT ALFONSO MARIA DE' (1696–1787), Italian moral theologian and founder of the Redemptorists, a doctor of the church, was born at Marianella, near Naples, on Sept. 27, 1696, the son of Giuseppe de' Liguori. He studied law, passed his examination for the doctor's degree at the age of 16 and practised law for eight years. Giving up the bar, he was ordained priest in 1726. In 1732 he founded the Congregation of the Most Holy Redeemer, commonly called the Redemptorists (see REDEMPTORISTS). In 1762 he became bishop of Sant' Agata de' Goti, about 30 mi. from Naples. He resigned this bishopric in 1775 and died on Aug. 1, 1787. He was canonized in 1839 and declared a doctor of the church by Pius IX in 1871. In 1950 he was named patron of moralists and confessors by Pope Pius XII. His feast is celebrated on Aug. 2.

Liguori wrote extensively. By 1953 his works had gone through about 18,000 editions and had been translated into 60 languages. They fall into three classes. (1) The first, in the field of moral theology, is headed by his *Theologia moralis*. This first appeared in 1748 and went through nine editions in his lifetime and more than 60 subsequently. He summarized it in *Praxis confessarii*. Another work in this class is *Homo apostolicus*. (2) The second class embraces his ascetical and devotional writings for priests, religious and lay persons. This includes *Visits to the Blessed*

Sacrament, The True Spouse of Christ (for nuns) and *Selva* (for priests) and *The Glories of Mary*. The last is one of the most influential and widely used manuals of Marian devotion, and it helped to shape the Marian doctrine. (3) The third class contains his dogmatic writings, such as *The History of Heresies*, his works on the infallibility of the pope and those on the power of prayer. This last theme he stressed so constantly that he is sometimes called the "doctor of prayer."

Liguori was also a celebrated preacher, a musician and a poet. He composed and put to music many hymns which are still favourites among the Italian people. His Christmas hymn "Tu Scendi dalle Stelle" is as closely associated with Christmas in Italy as are "Adeste Fideles" and "Silent Night" in other countries.

In theology Liguori is known as the principal exponent of equiprobabilism, a system of principles designed to guide the conscience when one doubts whether he is free from, or bound by, a given law. The system is based on the legal axiom "in doubt the presumption favours the possessor." Applying it to doubts of conscience, Liguori laid down these three principles: (1) In a doubt with equally probable reasons pro and con, a person is free from the obligation of the law if he has been free from it hitherto, for freedom is in possession and the presumption favours the possessor. (2) In a doubt with equally probable reasons pro and con, a person is bound to keep the law if he has been bound to it hitherto, for the law is in possession. (3) In a doubt when the reasons for the obligation of the law are considerably more probable than those for liberty, the law must be kept.

Collected editions of St. Alfonso Liguori's works have been published in Italian, French, German, Dutch and English. For bibliographies, see M. de Meulemeester, *Bibliographie générale des écrivains Rédemptoristes*, three volumes (1933–39) and *Histoire sommaire de la Congrégation du Très-Saint-Rédempteur* (1950); as well as A. Sampers, "Bibliographia Alphonsiana," *Spicilegium Historicum C. SS. R.*, pp. 248–271 (1953).

(RA. J. M.; F. J. C.)

LIGURIA, the smallest of the regions of Italy, is composed of the provinces of Genova, Imperia, La Spezia and Savona. Area 5,410 sq.km. (2,089 sq.mi.). Pop. (1961) 1,735,349. Liguria is shaped like a semicircle, reaching from the mouth of the Roia river to that of the Magra and from the French-Italian frontier to Tuscany. It is dominated by the Maritime Alps as far as the Cadibona pass and by the Ligurian Apennines east of that point. The narrow, picturesquely indented coastal fringe, the Italian Riviera, is customarily divided into a western section, the Riviera di Ponente, and an eastern section, the Riviera di Levante, the point of division being the apex of the Ligurian arc at Voltri. Most of the population is concentrated within this coastal area.

Because of the shelter from the winter winds afforded by the Alps and the Apennines, Liguria is particularly favoured in the production of early vegetables, flowers (especially in the westernmost section), olives and wine. Industries are concentrated in and around the city of Genoa, around Savona and along the shores of the Gulf of La Spezia. Genoa and La Spezia (qq.v.) contain the leading shipyards of Italy, and La Spezia is Italy's major naval base. Iron and steel and machinery are produced in Savona, Imperia (qq.v.) and Genoa; chemicals and petrochemicals at Genoa and at Vado outside Savona. Textiles and food industries are located in nearly all the major cities. Not least among the region's sources of income is the tourist trade, and there are numerous resorts scattered all along the coast.

The main railroad lines connect Genoa with Nice and Marseilles in France to the west, with Pisa and Rome to the southeast and with Milan, Turin and Switzerland to the north. An automobile toll road runs from Genoa to the Po valley. Genoa leads all Italian ports in volume of passenger and freight traffic.

Liguria, which derived its name from its pre-Roman inhabitants, came under the domination of Rome in the 1st century B.C. After short periods of Lombard and Frankish rule during the middle

ages, Genoa began to emerge as a leading power as early as the 11th century. By 1400 Genoa had not only gained control of the entire region but had become one of the principal maritime powers of Europe. Its commerce extended throughout the seas surrounding Europe, and it maintained permanent outposts as far east as the Crimea.

Throughout this period Genoa was involved in numerous conflicts with its competitors, especially Venice. It fell under foreign rule during the late 15th century but was restored to independence by Andrea Doria in 1528. Among its many outstanding seamen, Christopher Columbus was perhaps the most famous. Genoese independence came to an end under Napoleon I, and the congress of Vienna, in 1815, gave Liguria to Piedmont. During the Risorgimento, Liguria played a leading part in Italian affairs and, with Piedmont, contributed significantly to the union of Italy in 1860.

See also **LIGURIANS**; **ITALY**; and references under "Liguria" in the Index. (G. KH.)

LIGURIANS. The Liguri of ancient times, mentioned by Hesiod, are said in other classical sources to have made up the indigenous population of the northwestern Mediterranean coast from the mouth of the Ebro river in Spain to the mouth of the Arno river in Italy. It is a very difficult problem to decide who the Liguri were and also to differentiate them on the Spanish side from indigenous Iberians (*q.v.*). Much that has been written about them is based upon the evidence of place names, especially the distribution of roots ending in *-asc*, *-esc*, *-osc* which are common in the west of Liguria but also occur outside the true Ligurian area; *e.g.*, in the Basque provinces of northern Spain.

In the earliest historical period, "Liguria" referred to an area where in the Early Iron Age Hallstatt culture there was great similarity in the Urnfield pottery and metal types (including a peculiar razor type) between Catalonia, Languedoc, Roussillon, southern Switzerland and northern Italy, through all of which burial in flat graves was prevalent. It has been argued that it was to this Early Iron Age cultural unity that the Greeks applied the ethnic name "Liguri" although the objection can be raised that this identity in Urnfield types no longer applied at the period of the first Greek settlements.

The affinities which exist between the peoples stretching from the Pyrenees to the Arno in prehistoric times are Neolithic rather than Iron Age, and it is probable that the Urnfield elements of the Early Iron Age left the indigenous ethnic stratum undisturbed. This stratum was basically a Neolithic one, and it is to this or rather to types of Neolithic culture in this area that archaeologists are now apt to apply the ethnic term "Ligurian." This Neolithic mode of life continued in village settlements in remote places despite intrusive Celtic elements of later Urnfield invasion, and it was probably to loose political groupings of these people that classical authors attach the name. Rough handmade pottery with finger-impressed decoration of basically Neolithic type has been found in the lowest levels of the Greek city of Ampurias in Spain and of the southern French Celtic fortresses of Ensérune and Cayla de Mailhac, at both of which Iberian influence was strong from the 5th century B.C. onward.

No texts speak of Ligurians (or of Iberians for that matter) in southern Gaul as nations, or attribute definite racial characteristics to them. Ancient authors (Strabo, iv, 6, 2 ff.; Diodorus Siculus, v, 39) describe them as a rough and strong people whose piracy the Romans deplored. These, however, are late texts and refer to the celticized Ligurians (Celtoligures) between the Rhône and the Arno rivers. Strabo tells us distinctly that they were of a different race from the Gauls or Celts, and Diodorus mentions that they lived in villages and made a difficult living from the rocky mountainous soil.

Their boldness caused them to be in great demand as mercenaries. They served Hamilcar in 480 B.C. and the Sicilian Greek colonies in the time of Agathocles and openly sided with Carthage in the Second Punic War. Not until 180 B.C. were steps taken for their final reduction by Rome, when under the proconsuls P. Cornelius Cethegus and M. Baebius 40,000 Ligurians were deported to Samnium and settled near Beneventum (Benevento).

Stretching from Gaul to Etruria, Liguria was made the ninth division of Italy by Augustus and contained the following tribes: the Friniates on the northern slopes of the Apennines, the Briniates and the Apuani in the Vara and Magra valleys respectively, the Genuates around Genoa, and the Veturii to the west of these, the Vediantii around modern Venice, the Intemelii whose capital was Albium Intemelium (modern Ventimiglia) and the Ingauni whose capital was Albium Ingaunum (modern Albenga). North of the Apennines there were lesser tribes, the Vagienni around Augusta Vagiennorum (modern Bene), the Statielli around Aquae Statiellae (modern Acqui). The Taurini near modern Turin and many other tribes listed by Pliny and Livy were also considered Ligurians.

LI HUNG-CHANG (1823–1901), Chinese statesman who symbolized Confucian China's inability to adjust to the modern western-dominated world. For 25 years after 1870, he was governor-general of the northern metropolitan province of Chihli but even this long and able tenure of the highest provincial post in the Ch'ing (Manchu) system did not prevent increasingly damaging military defeats which hastened the final collapse of the dynastic system (1911).

Born in Ho-fei, Anhwei, on Feb. 15, 1823, Li received the prescribed Confucian education, and first won recognition for his part in the suppression of the T'ai p'ing rebellion (1850–64). But the dynasty had other enemies and after Li became Chihli governor-general he was continuously engaged in diplomacy, trying to parry the demands of Great Britain, France, Russia and particularly Japan, whose modernization, like China's, had started only in the 1860s. Yet he had to see or report defeats by the French (war of 1884–85), the Japanese (war of 1894–95), and the western powers and Japan (after the antiforeign Boxer uprising of 1900).

In this quarter-century Li laboured to enhance China's strength. He modernized his army with products of his new arsenal at Tientsin and equipped his northern fleet with purchased late-model European warships, showing a respectable force by the 1890s. Yet Li was an official in a decentralized system, under Manchu domination, and the complex politics of dynastic decline encouraged him to treat these forces almost as personal possessions. Thus he managed not to send in his fleet when France attacked South China in 1884–85. Conversely, he was not able to unify the other new provincial fleets and arsenals into a single force, and so in turn had to send his demoralized northern fleet into unsupported action against Japan in the 1890s. His commercial ventures, which included shipping and mining, were similarly vitiated by a mixture of personal and official concerns. In a word, China's late 19th-century modernization, designed to save the dynasty and the traditional life, was disastrously hampered by institutional contradictions, which are nowhere better illustrated than in Li's unprecedented career. He died on Nov. 7, 1901.

See the entry for Li Hung-chang in A. W. Hummel (ed.), *Eminent Chinese of the Ch'ing Period*, 2 vol. (1943–44). (J. L. RN.)

LILAC, any shrub of the genus *Syringa*, family Oleaceae. The genus contains more than 25 species of ornamental fairly deciduous shrubs and trees, native in eastern Europe and temperate Asia. They have opposite, generally entire leaves and large panicles of small regular flowers, with a bell-shaped calyx and a four-lobed cylindrical corolla, with the two stamens characteristic of the family attached at the mouth of the tube.

The lilacs are among the commonest and most beautiful of fragrant, spring-flowering shrubs. Scores of fine varieties, some with double flowers, have been developed, mostly in France, and are preferred by many to the common lilac.

The common lilac (*S. vulgaris*) is said to have come from Persia in the 16th century, but is doubtfully indigenous to Hungary, the borders of Moldavia, etc. Two kinds of *Syringa*, viz., *alba* and *caerulea*, are figured and described by John Gerard (*Herball*, 1597); these he calls the white and the blue pipe privets. The

white is the common privet, *Ligustrum vulgare*, which, with the ash tree, *Fraxinus excelsior*, is the only member of the family found wild in Great Britain. The blue pipe privet is the lilac, as both figure and description agree accurately with it. It was carried by the European colonists to northeast America and is widely grown in gardens of Canada and the northern and central United States.

The Persian lilac of gardens (*S. persica*), also known as the Chinese or Rouen lilac, a small shrub four to six feet high with intense violet flowers appearing in May and June, is much cultivated for ornament. Of other species, *S. josikaea*, from Transylvania, has scentless bluish-purple flowers; *S. emodi*, a native of the Himalayas, is a handsome shrub with large ovate leaves and dense panicles of purple or white strongly scented flowers.

Lilacs grow freely and flower profusely in almost any soil and situation, but when neglected are apt to become choked with suckers, which shoot up in great numbers from the base. These should be removed to promote better growth, and the suckers used for propagation. Vigorous growth and flowering depend on adequate feeding and proper pruning. Well-rotted cow manure, applied as a four-inch deep dressing about every two years in early spring, is preferred to prepared chemical fertilizers, which tend to induce woody vegetative growth at the expense of flowering shoots. Flower buds set in the autumn. Flower clusters produced in the spring should be removed when they fade. Powdery mildew, a common disease of lilacs, produces a grayish to whitish powder on the leaves; fungicidal sprays, applied during early spring growth, afford control.

Notable collections of lilacs are found at Rochester, N.Y., at the Arnold arboretum, Jamaica Plain, Mass., and at Swarthmore college, Swarthmore, Pa. In 1953 the U.S. Lilac Survey committee issued *Lilacs for America*, which lists all the varieties of *S. vulgaris*.

Syringa is also a common name for the mock orange, which are unrelated shrubs of the genus *Philadelphus* (q.v.). (N. Tr.)

LILBURNE, JOHN (1614–1657), English republican and leader of the extremists known as the Levellers (q.v.), was born at Greenwich in 1614. After an early apprenticeship to a London cloth merchant he soon joined the subversive opposition to the church policy of Charles I's personal rule (1629–40), helping to smuggle in and circulate pamphlets printed in the Netherlands. For this he was tried by the Star Chamber in 1638, fined £500, whipped, pilloried and imprisoned until he submitted. He even used the pillory as a pulpit until he was firmly gagged. Lilburne remained in prison until the Long parliament liberated him in Nov. 1640, when Oliver Cromwell spoke for him. On the outbreak of the Civil War Lilburne was commissioned as a captain in the parliamentarian forces. Taken prisoner at Brentford his life was saved when parliament threatened reprisals if he were not spared and exchanged. When he resigned in April 1645 rather than take the Covenant, Lilburne had risen to the rank of lieutenant colonel.

Thereafter his career was fused with the history of the Levellers. He wrote quantities of pamphlets but his special contribution was his vindication of the legal rights of Englishmen, for which he gained the nickname "Free-born John." He quoted Sir Edward Coke almost as often as the Bible and was even criticized by his fellow Levellers William Walwyn and Richard Overton for attaching exaggerated importance to Magna Carta. Finally Lilburne took the view that the existing law and constitution were inadequate to defend the birthright of Englishmen. He proposed manhood suffrage and extensive reform of the law; past laws were justified only if they harmonized with reason. Thus he rejected

the common-law appeal to precedent and custom.

Lilburne was fierce in his criticism first of the Presbyterian parliament and then of the army's Independent leaders for failing to meet the Levellers' demands. Often arrested, his popularity ensured his acquittal by juries. He even insisted, when on trial in Oct. 1649, that juries were judges of law as well as fact, while the judges were a Norman innovation. Banished by parliament in 1652, Lilburne returned in 1653 after the dissolution of the Rump. He was put on trial and his acquittal by a London jury led to a great popular demonstration which affected the army and alarmed the government. He was therefore kept in prison until 1655 by which time he had become a Quaker and was prepared to offer security for his good behaviour.

Lilburne died at Eltham in Kent on Aug. 29, 1657.

See M. A. Gibb, *John Lilburne the Leveller* (1947).

LILIACEAE, the lily family of plants, containing about 240 genera and 4,000 species, many of economic importance. The family includes plants of highly diverse appearance but of basically similar flower structure. Most Liliaceae are perennials that grow from bulbs (tulip, hyacinth, onion) or rhizomes (asparagus, lily of the valley); some are shrubs (butcher's-broom); some are vines, either herbaceous (glory lily) or woody (cat brier); and a few are tree-like (Joshua tree).

The lily family is cosmopolitan. The majority of species is found in temperate and subtropical regions, although some representatives occur as far north as northern Greenland (*Tofieldia coccinea*) and as far south as Tierra del Fuego (*Luzuriaga marginata*). Liliaceae are especially plentiful in South Africa, which has 60 genera and approximately 1,000 species. About 60 genera occur in North America north of Mexico. California alone has about 25 genera and 120 species. Twenty genera and almost 40 species are found in the British Isles.

Some Liliaceae are well-known garden ornamentals, including the true lily (*Lilium*); crown imperial (*Fritillaria imperialis*); Mariposa lily (*Calochortus*); glory-of-the-snow (*Chionodoxa*); day lily (*Hemerocallis*); plantain lily (*Hosta*); hyacinth (*Hyacinthus*); grape hyacinth (*Muscari*); lily of the valley (*Convallaria majalis*); star-of-Bethlehem (*Ornithogalum umbellatum*); scilla (*Scilla*); tulip (*Tulipa*); and foxtail lily (*Eremurus*). Some Liliaceae are chiefly greenhouse subjects, such as the African lily (*Agapanthus africanus*); St. Bernard's lily (*Anthericum liliago*); gasteria (*Gasteria*); ti (*Cordylina terminalis*); and butcher's-broom (*Ruscus aculeatus*). Bowstring hemp or snake plant (*Sansevieria*) and cast-iron plant (*Aspidistra elatior*) are popular house plants.

Food plants that are members of the Liliaceae are asparagus (*Asparagus officinalis*), onion (*Allium cepa*), chives (*Allium schoenoprasum*), leek (*Allium porrum*) and garlic (*Allium sativum*). Of the several fibre plants in the family the most important are New Zealand hemp (*Phormium tenax*) and bowstring hemp. Some of the drugs obtained from liliaceous plants include aloes, the dried juice from various species of *Aloe*, used mainly as a purgative; colchicum, the dried corm of the meadow saffron or autumn crocus (*Colchicum autumnale*), used in the treatment of rheumatism and gout; and red squill, the dried inner bulb scales of the sea squill (*Urginea maritima*), used as an expectorant and stimulant and also as a rat poison. Colchicine, an alkaloid derived from *Colchicum*, is used by plant breeders in the production of new varieties of plants. Sarsaparilla, a flavouring in certain beverages and medicines, is extracted from the roots

J. E. DOWNWARD

LILAC (*SYRINGA VULGARIS*)

J. E. DOWNWARD

PLANTAIN LILY (*HOSTA ELATA*). ONE OF THE MANY SPECIES OF LILIACEAE

of several tropical American species of *Smilax*. Acaroid resin or "gum accroides," used in varnishes, sizing and inks, is obtained from several species of grass trees (*Xanthorrhoea*) of Australia. Socotra dragon's blood, another resin, comes from the dragon tree (*Dracaena cinnabari*) of Socotra and is used mainly as a pigment.

A few Liliaceae are weedy plants. In localities where wild onions and leeks are common, cattle may graze upon them and yield milk with an off-flavour. Cat brier (*Smilax rotundifolia*) and saw brier (*Smilax glauca*), which are prickly woody vines, may form impenetrable thickets in woods, clearings and abandoned fields. Some Liliaceae are poisonous. In western United States, species of 'death camas' (*Zygadenus*) may cause serious losses among stock that graze upon them. Also poisonous to stock are bunchflower (*Melanthium virginicum*), fly poison or stagger grass (*Amianthium muscaetoxicum*), false hellebore (*Veratrum viride*), meadow saffron, grass trees and several south African species of *Ornithogalum*. Hyacinth bulbs caused acute purgation and eventual death in cattle when used as feed during World War II in Holland. All parts of lily of the valley are poisonous if eaten.

Most genera of Liliaceae have a limited distribution. Many are confined to Australia, South Africa, southern and western United States, Mexico and western Asia. In contrast, some genera (e.g., *Smilax*, *Tofieldia* and *Allium*) have a wide distribution and are found in both the old and new worlds. Among the larger genera of the family are *Allium*, *Smilax*, *Aloe*, *Asparagus*, *Scilla* and *Lilium*. Liliaceae are dominant plants only in some desert regions, as in southwestern United States, where species of *Yucca* are characteristic; southern Africa, where large aloes may be abundant locally; and Socotra, where dragon-tree "forests" occur.

Familiar native Liliaceae in the United States are: Turk's-cap lily (*Lilium superbum*); dog's-tooth violet, adder's-tongue or trout lily (*Erythronium*); ramp or wild leek (*Allium tricoccum*); wild onion (*Allium cernuum* and other species of *Allium*); soapweed (*Yucca glauca*), Spanish bayonet (*Yucca aloifolia*); Joshua tree (*Yucca brevifolia*); Solomon's-seal (*Polygonatum*); false Solomon's-seal or false spikenard (*Smilacina racemosa*); wild lily of the valley (*Maianthemum canadense*); trillium or wake-robin (*Trillium*); red-berried bamboo (*Smilax walteri*); cat brier; oonow (*Brodiaea congesta*); death camas; and bear grass (*Xerophyllum tenax*). Some British Liliaceae are bog asphodel (*Narthecium ossifragum*); lily of the valley; Bath asparagus (*Ornithogalum pyrenaicum*); bluebell or wild hyacinth (*Scilla nonscripta*); crow or field garlic (*Allium vineale*); and meadow saffron.

For the most part, flowers of Liliaceae, which may be borne singly or in clusters, are easily recognized by their six similar petal-like perianth segments (three sepals and three petals), which in some species are united into a tube; by their six stamens; and by their three-chambered ovary, which is superior (i.e., it is situated above the point of attachment of the perianth segments). Well-known members of the family whose flowers differ from this pattern include trilliums, in which the sepals and petals are distinctly unlike, and wild lily of the valley (*Maianthemum*), which has four perianth segments, four stamens and a four-chambered ovary. Liliaceous flowers are generally bisexual, containing both pistil and stamens. Among the few exceptions are *Smilax* and *Chamaelirium* (fairy wand), in which the flowers are unisexual, male and female occurring on separate plants. The fruit of Liliaceae is typically a three-chambered capsule, as in tulip and day lily; or a berry, as in Solomon's-seal and asparagus.

Leaves of Liliaceae may be clustered at the base of the plant or may be scattered along the stem alternately or in whorls. The leaves are generally parallel-veined and leaflike, although in some species they are scalelike. In certain Liliaceae the smaller branches are much flattened and are leaflike in appearance and function, as in butcher's-broom and some species of *Asparagus*. Such leaflike branches are called cladodes and can be distinguished from true leaves because each is subtended by a scale (the true leaf) and each may bear one to several flowers. The "leaves" of garden asparagus are needlelike cladodes borne in tufts.

Flowers of Liliaceae are, for the most part, insect pollinated. Insects visit some species for nectar (scilla, Solomon's-seal, onion, hyacinth, meadow saffron), others for pollen (tulip, lily of the

valley, yucca). In carrion flowers (*Smilax*), herb Paris (*Paris*) and some trilliums, the flowers produce a fetid odour, like that of decaying meat, which attracts carrion-loving flies. Many Liliaceae produce rather heavy seeds that have no special adaptation for dispersal far from the parent plant. Some (e.g., certain *Lilium*) have light, flat, winged seeds that are spread by wind, as are the minute seeds of *Tofieldia* and *Narthecium*. Liliaceae whose fruit is a berry are bird distributed.

Certain anatomical and morphological data indicate that the Liliaceae include a number of genera that either are not closely enough related to be placed in the same family or seem to be more closely related to families other than the Liliaceae. By some students of the problem, notably J. Hutchinson (1934), the Liliaceae are divided into several families. The segregate families recognized by Hutchinson appear, for the most part, to represent natural groups; however, they have not been accepted universally by botanists. United States and British genera transferred by Hutchinson from the Liliaceae include *Smilax*, to the smilax family (Smilacaceae); *Ruscus*, to the ruscus family (Ruscaceae); *Trillium*, *Paris* and *Medeola*, to the trillium family (Trilliaceae); *Allium*, to the amaryllis family (Amaryllidaceae); and *Yucca*, to the agave family (Agavaceae).

See J. Hutchinson, *The Families of Flowering Plants*, vol. 2, "Monocotyledons" (1934); K. Krause, "Liliaceae" in A. Engler and K. Prantl, *Die Natürlichen Pflanzenfamilien*, Bd. 15a:227-386 (1935). (J. W. Tr.)

LILIENCRON, (FRIEDRICH ADOLF AXEL) DETLEV, FREIHERR VON (1844-1909), German writer of novels and poems largely concerned with the glory and violence of war, was born at Kiel on June 3, 1844. He served as a regular officer in the campaigns of 1866 and 1870-71, left the army because of debts in 1875 and, after spending some time in America, became a civil servant, finally being in charge of the administration in Kellinghusen in Holstein, where he remained till 1887. He had begun writing in the early 1880s and his first volume of poems (*Adjutantenritte und andere Gedichte*, 1883) attracted some attention. He lived subsequently in Munich, Berlin and Altona and finally settled in Alt-Rahlstedt near Hamburg, where he died on July 22, 1909.

Liliencron published several plays (*Die Rantzow und die Pogwisch*, 1886) and a novel (*Breide Himmelsbüttel*, 1887), but, apart from his poetry, it was on short stories that he concentrated. In several collections (*Krieg und Frieden*, 1891; *Kriegs-novellen*, 1895) he painted realistic and arresting pictures of war. His lyrical poetry exploited a new manner of conveying broad impressions without sacrificing accuracy of detail, making much use of the acoustic and nervous energy of the words in poems written on a variety of subjects—nature, battle, the life of the soldier or of the Prussian Junker. His feeling for the emotional tone of isolated moments of experience gives his poetry great immediacy and vividness, but it lacks any profound sense of large coherence. He achieved some success also in humorous pieces, particularly the mock-epic *Poggfred* (1896, extended 1908). His reputation stood very high for a time but later declined considerably.

Dehmel, 2 vol. (1910); to his publisher, ed. by W. Friedrich (1910); to his first wife, ed. by H. Spiero (1925). See also J. Bierbaum, *Liliencron*, 2nd ed. (1910); H. Maync, *Liliencron* (1920); H. Leip, *Liliencron* (1938).

(W. D. W.)

LILIENTHAL, OTTO (1848-1896), German aeronautical pioneer, on whose work later, more successful engineers such as Octave Chanute and the Wright brothers drew heavily, was born at Anklam, in Prussian Pomerania, on May 23, 1848. As boys, he and his brother Gustav studied the flight of birds. Later, after graduation from the trade school at Potsdam and the Berlin Trade academy, Otto Lilienthal experimented with flying models with flapping wings and with gliders. His book on bird flight (*Der Vogelflug als Grundlage der Fliegekunst*, 1889) and his essays on flying machines (1894) were recognized as the basic works in aeronautics. Lilienthal made several hundred flights in gliders of

his design from an artificial hill near Lichterfelde. On Aug. 9, 1896, attempting to glide from a hill in the Stollerier mountains near Rhinow, he was killed when his glider turned over in flight. See GLIDING: *History of Gliding Experiments*. (S. P. J.)

LILITH, a female demon of Jewish folklore, equivalent to the English vampire. The personality and name ("night monster") are derived from a Babylonian-Assyrian demon Lilit or Lilu. Lilith was believed to have a special power for evil over children. The superstition was extended to a cult surviving among some Jews even as late as the 7th century A.D. In the rabbinical literature Lilith becomes the first wife of Adam, but flies away from him and becomes a demon.

LILLE (formerly spelled L'ILE or LISLE; Flemish RYSEL or RYSSSEL), an industrial city of northern France, capital of the *département* of Nord and of French Flanders, 160 mi. (258 km.) N.E. of Paris by rail. Pop. (1962) 199,033. Lille lies in a rich agricultural and industrial plain on the right bank of the canalized Deûle. With Roubaix and Tourcoing (*qq.v.*) it forms one of the largest urban agglomerations in France, a continuously built-up and expanding area with a population of about 750,000.

Lille is the headquarters of the I army corps and has an *enceinte* and a pentagonal citadel, one of Vauban's finest works (the "queen of citadels," he said), west of the city, across the Deûle. With its barracks and arsenal, the citadel is surrounded by a park. Before 1858 the town, fortified by Vauban about 1668, occupied an elliptical area of about 2,500 by 1,300 yd., with the church of Notre Dame de la Treille in the centre. At that time, however, the southern ramparts and ditches were replaced by the Boulevard de la Liberté, a straight line from the freight railway station to the citadel. The area of the town was thus more than doubled. Eventually, as the city expanded toward Roubaix and Tourcoing, the three became one great conurbation.

At the demolition of the southern fortifications, the Paris gate, erected in 1682 to the design of Simon Volland in honour of Louis XIV and at his expense, after the conquest of Flanders, was preserved. On the east are the Ghent (1617) and Roubaix (1622) gates, in Renaissance style, in bricks of different colours. The city's churches possess valuable pictures (including an important Rubens in the church of St. Catherine), and the modern cathedral of Notre Dame de la Treille has a statue of the Virgin which is an object of pilgrimage. Lille was made a bishopric in 1913. The Vieille Bourse (17th century) separates the Place du Théâtre and the present Place du Général de Gaulle (who was born at Lille). The Hôtel d'Aigremont, the Hôtel Gentil and other houses are in the Flemish style. The Palais des Beaux-Arts contains a museum and an art gallery, the latter among the richest in France. During World War I, damp (caused by lack of heating) and deterioration of the glass casings resulted in damage to some of the canvases. Throughout World War II great precautions were taken to safeguard the museum's treasures, and there was almost no damage. The large military hospital was once a Jesuit college.

Lille is the seat of a prefect and has tribunals of first instance and of commerce, a commercial arbitration council, a chamber of commerce and a branch of the Bank of France. It is the seat of an *académie* and has a university (established 1887) with faculties of laws, letters, science and medicine and pharmacy, and a number of affiliated institutes. There are also the Catholic University of Lille, a national technical school, schools of music and fine arts, and the industrial and Pasteur institutes.

Lille, with Roubaix-Tourcoing and Armentières, is one of the world's great textile centres. The spinning of flax thread for sewing and lacemaking is specially connected with Lille, and the city has flax, hemp, jute, cotton and woolen mills. There are important iron and steel works and manufactures of locomotives and textile machinery; chemical industries, breweries, distilleries and beet-sugar refineries are also significant.

Lille is an important railway junction, and the canalized Deûle affords communication with neighbouring ports and with Belgium. Trade is chiefly in the raw material and machinery for the city's industries, in its industrial products and in the wheat and other agricultural products of the surrounding district. An international commercial fair is held annually.

In 1030 Count Baldwin IV of Flanders surrounded with walls a little town which had arisen around the castle of Buc. In the first half of the 13th century, the town obtained communal privileges. Destroyed by Philip Augustus in 1214, it was rebuilt by Joan of Constantinople, countess of Flanders; it was besieged and retaken by Philip the Fair in 1297. After having taken part with the Flemings against the king of France, it was ceded to the latter in 1312. In 1369 Charles V, king of France, gave it to Louis de Mâle, who transmitted his rights to his daughter Margaret, wife of Philip the Bold, duke of Burgundy. Under Burgundian rule Lille prospered and its merchants were at the head of the London Hansa. Philip the Good made it his residence. With Flanders it passed from the dukes of Burgundy to Austria, and then to Spain. After the death of Philip IV of Spain, Louis XIV reclaimed the territory and besieged Lille in 1667. He forced it to capitulate, but preserved its liberties. In 1708, after heroic resistance, it surrendered to Prince Eugene and the duke of Marlborough. The treaty of Utrecht restored it to France.

In World War I, after several days' bombardment, the Germans entered the city on Oct. 12, 1914; it was occupied till Oct. 1918, when the Germans were outflanked by the Allied capture of neighbouring towns. The deportation of a large number of citizens in 1916 was the culminating point of tyranny suffered by the people of Lille under war conditions. The city was not shelled by the Allies, though it lay within range of the guns. In World War II, on the other hand, it was severely damaged by Allied air raids.

LILLEBONNE, a town of France in the Seine-Maritime *département*, 3½ mi. N. of the Seine and 24 mi. E. of Le Havre by the Western railway. Pop. (1962) 7,672. It lies in the valley of the Bolbec at the foot of wooded hills. Lillebonne—under the Romans, *Iuliobona*—was the capital of the Caletes and became an important focus of Roman roads. The remains of ancient baths and of a great theatre have been brought to light. The medieval fortifications were built of materials from the theatre. Tradition has it that William the Conqueror in 1066 decided upon the invasion of England at his château in Lillebonne. The church of Notre-Dame has a 16th-century tower and portal; the donjon of a 13th-century castle stands in the park. In the town hall is a museum of archaeology, local history, folklore and natural history. The principal industry was the spinning of wool and cotton. Between Lillebonne and the Seine river is an important petrochemical centre. (M. Yv.)

LILLIBURLERO (LILLIBULLERO), a 17th-century English political song that played an important part in driving James II from the throne in 1688. Among the many verses, two run as follows:

Dare was an old prophesy found in a bog,
Lilli burlero, bullen a-la
"Ireland shall be ruled by an ass and a dog."
Lilli burlero, bullen a-la
Lero, lero, lilli burlero, lero, lero, bullen a-la,
Lero, lero, lilli burlero, lero, lero, bullen a-la.

And now dis prophesy is come to pass,
Lilli burlero, etc.
For Talbot's de dog and Ja. s is de ass.
Lilli burlero, etc.

Written in 1687 by Thomas (1648–1715), (afterward marquess of) Wharton, the verses were intended to discredit the administration in Ireland of Richard Talbot (1630–91), earl of Tyrconnel, after his appointment as viceroy in 1687. According to Gilbert Burnet, bishop of Salisbury, in his *History of His Own Time* (1724), "The whole army, and at last the people, both in city and country, were singing it perpetually. And perhaps never had so slight a thing so great an effect." The earliest known printed version of the tune now associated with the words appeared in Robert Carr's *The Delightful Companion* (1686), for recorder or flute. In *Musick's Hand-Maid* (1689: originally published by John Playford in 1663) it is called "A New Irish Tune" and Henry Purcell's name is subscribed, whether as composer or merely as arranger of the version for harpsichord is not clear. The words, with the tune printed above, were issued on a single sheet

in 1688; it was reprinted in a number of different collections during the next 100 years.

(D. Po.)

LILLIE, FRANK RATTRAY (1870–1947), U.S. zoologist, specializing in embryology, who demonstrated that fertilization involves the interaction of specific substances borne by the egg and sperm (fertilizin theory), and that embryonic sex differentiation is controlled by sex hormones circulating in the blood between fetal cattle twins (freemartin theory). Born in Toronto, Ont., on June 27, 1870, he was educated at the University of Toronto and The University of Chicago (Ph.D., 1894). Returning to The University of Chicago in 1900, he became professor of embryology in 1906 and distinguished service professor in 1931. He served as chairman of the department of zoology (1910–31) and dean of the division of biological sciences (1931–35). Through his leadership (1908–42) the Marine Biological laboratory (Woods Hole, Mass.) was built into a research institution of international distinction.

Lillie was founder and first president of the Woods Hole Oceanographic institution. He served as president of the National Academy of Sciences (1935–39) and was awarded its Agassiz medal in 1940. His books include *Development of the Chick* (1908, 1919), *Problems of Fertilization* (1919) and *The Woods Hole Marine Biological Laboratory* (1944). He died in Chicago on Nov. 5, 1947.

For a full account of Lillie's career see *Biological Memoirs*, National Academy of Sciences, vol. 30 (1957).

(B. H. W.)

LILLO, GEORGE (1693–1739), English dramatist whose tragedy *The London Merchant, or the History of George Barnwell* (1731) revived an interest in domestic themes and influenced the sentimental drama of France and Germany, was born in London, Feb. 4, 1693, the son of a Dutch jeweler. He was for many years a partner in his father's business. His first piece *Silvia, or the Country Burial* (1730), a ballad opera, was produced at Lincoln's Inn Fields. *The London Merchant*, produced by Colley Cibber at Drury Lane, is founded on "an excellent ballad of George Barnwell, an apprentice of London who . . . thrice robbed his master, and murdered his uncle in Ludlow." Lillo had gone back to the Elizabethan domestic drama of passion of which the anonymous *Yorkshire Tragedy* is a type. Scoffing critics called it, with reason, a "Newgate tragedy" but it was regularly acted for many years at holiday seasons for the moral benefit of the apprentices. The last act contained a scene generally omitted on the London stage, in which the gallows actually figured. In 1734 Lillo celebrated the marriage of the Princess Anne with William IV of Orange in *Britannia and Batavia*, a masque. His other dramas were *The Christian Hero* (1735); *Fatal Curiosity* (1736); an adaptation of *Pericles, Prince of Tyre* entitled *Marina* (1738); and *Elmerick, or Justice Triumphant* (1740).

Lillo died in London, Sept. 3, 1739. His unfinished version of the anonymous Elizabethan tragedy *Arden of Feversham* was completed by Dr. J. Hoadly and produced in 1759. His *Dramatic Works, with Memoirs of the Author by Thomas Davies* were published in two volumes, 2nd ed. (1810).

See E. Bernbaum, *The Drama of Sensibility* (1915).

LILLY, WILLIAM (1602–1681), English astrologer immortalized as Sidrophel in Samuel Butler's *Hudibras*, was born on May 1, 1602, at Diseworth in Leicestershire, and was educated at the school of Ashby-de-la-Zouch. In April 1644, he began publishing his astrological almanacs, which received serious attention from some of the most prominent members of the Long Parliament. Like all successful astrologers, he tempered the indications given by the aspects of the heavens with his knowledge of current events, with the result that his predictions often showed a sympathy with the parliament. For this reason, and because he misjudged the scientific revolution that spread so rapidly in England during the 17th century, Lilly fell into disrepute after the Restoration.

He died at Hersham, Surrey, on June 9, 1681.

(O. J. E.)

LILY, WILLIAM (1468?–1522), English Renaissance scholar and classical grammarian, was born at Odiham, Hampshire, about 1468. After graduating at Oxford university he traveled in the south and east of Europe, during which time he studied

Greek. He became the personal friend of William Grocyn, Thomas Linacre and Sir Thomas More. After teaching privately in London he was appointed high master of Dean Colet's refoundation of St. Paul's school (1512–22). He died in 1522.

Lily was a pioneer of Greek learning in England and one of the authors of the Latin grammar which bears his name. In 1540 Henry VIII ordered it to be used in all English grammar schools. In the Anglican canons of 1604 the bishop, when visiting a school, was directed to ask if the "Royal Grammar" was used.

Lily's Grammar was severely criticized by schoolmasters, and numerous revisions were made which corrected errors, eliminated needless complications and contributed useful additions. The most important criticism concerned the Latin syntax "by which children have been usually put upon learning the construction of a language, they were unacquainted with, from rules given them in that very language." Thus English translations of the rules and the syntax were made by William Haine of Merchant Taylors' school (1637), Richard Busby (1659) and many others. Charles Hoole published an edition in 1651 with an English translation on the left-hand pages.

Editions incorporating recognized emendations were also published at Cambridge (1634 and 1640) and at Oxford (1636 and 1687). John Ward's edition (1732) was commonly used in 18th-century English schools. Revised in 1758 and appropriated by Eton college as the *Eton Latin Grammar*, it was finally superseded ten years later by the *Public School Latin Grammar*.

Curtis, *History of Education in Great Britain*, 4th ed. (1957); Watson Foster, *The English Grammar Schools to 1660: their Curriculum and Practice*, ch. xv–xviii (1908).

(S. J. C.)

LILY, the common name applied to herbaceous flowering plants belonging to *Lilium*, the typical genus of the family Liliaceae, embracing about 80 species, all confined to the northern hemisphere and widely distributed throughout the north temperate zone. However, the word "lily" is loosely used in connection with many plants which are not really members of the genus *Lilium*, but belong to genera which are quite distinct botanically. The earliest in cultivation were described in 1597 by John Gerard, who figured eight kinds of true lilies, including *L. candidum* and a variety, *bizantinum*; two umbellate forms of the type *L. bulbiferum*, named *L. aureum* and *L. cruentum latifolium*; and three with pendulous flowers, apparently forms of the martagon lily. Parkinson, in his *Paradysus* (1629), described five varieties of martagon, six of umbellate kinds, together with one American, *L. canadense*.

The Madonna lily, *L. candidum*, was one of the commonest garden flowers of antiquity, appearing in the poets from Homer on, sharing popularity with the rose and the violet. Roses and lilies are thought to have entered Greece from the east by way of Phrygia, Thrace and Macedonia. Mythologically the white lily *Rosa junonis* (called Madonna in the late 19th century) was fabled to have sprung from the milk of Hera. As the plant of purity it was contrasted with the rose of Aphrodite.

The Greek word *krinon* (lily), on the other hand, included red and purple lilies. The red lily was that best known in Syria and Judaea, and the lily of the Old Testament may be conjectured to be a red lily from the metaphor used in Song of Solomon v, 13 ("His lips are lilies") unless the allusion is to the fragrance rather than to the colour. The "lilies of the field" (Matt. vi, 28) are quite certainly *Anemone coronaria*, the poppy anemone, which is common in Palestine where lilies are not.

J. HORACE MCFARLAND CO.

MADONNA LILY (LILIAM CANDIDUM). KNOWN FROM ANTIQUITY

True Lilies.—In North America about 20 native species of lily occur. In the eastern half of the continent the best known are the wood lily (*L. philadelphicum*), the meadow lily (*L. canadense*), the Turk's-cap lily (*L. superbum*) and the bell lily (*L. grayi*). Noteworthy among the ten native lilies found in the Pacific states are the Washington lily (*L. washingtonianum*), the Columbia lily (*L. columbianum*) and the Humboldt lily (*L. humboldtii*). None of these American lilies compares with those from the Himalayas, Korea, China and Japan as garden plants. But many magnificent hybrid lilies were developed after 1930 on the Pacific coast by such outstanding plant breeders as E. F. Palmer and Jan de Graaff. No true lily is found native in Great Britain.

The structure of the flower represents the simple type of monocotyledons, consisting of two whorls of petallike perianth lobes, of three free parts each; six free stamens; and a consolidated pistil of three carpels, ripening into a three-valved capsule containing many winged seeds. In form, the flower assumes three types: trumpet-shaped, with a more or less elongated tube (e.g., *L. longiflorum*, the white trumpet lily, and *L. candidum*, the Madonna lily); an open form with spreading perianth leaves (e.g., *L. auratum*); or assuming a pendulous habit, with the tips strongly reflexed (e.g., the martagon type). All have scaly bulbs which, in three western American species such as *L. humboldtii*, are remarkable for being somewhat intermediate between a bulb and a creeping rhizome. *L. bulbiferum* and its allies produce aerial reproductive bulbils in the axils of the leaves.

The bulbs of several species are eaten in some areas of the world. Medicinal uses were once ascribed to the species, but none appears to have any marked properties in this respect. From *L. longiflorum* was developed in Oregon the Croft lily, the commonest Easter lily in the United States.

The noble *L. auratum*, with its large white flowers, having a yellow band and numerous red or purple spots, is a magnificent plant when grown to perfection; and so are the varieties called *rubrovittatum* and *Crimson Queen*, which have the central band crimson instead of yellow, and the broad-petaled *platyphyllum* and its almost pure white subvariety called *virginale*. Of *L. speciosum*, the Japanese lily (well known to most gardeners as *lancifolium*), the true typical form and the red-spotted and white varieties are impressive plants for late summer blooming.

The tiger lily, *L. tigrinum*, and its varieties *fortunei*, *splendens* and *plenesccens* are among the best species for the flower garden.

The pretty *L. leichtlinii* and *L. monadelphum*, with drooping yellow flowers, and the scarlet droop-flowered *L. tenuifolium* comprise, with those already mentioned, a series of the finest hardy flowers of the summer garden. The Indian *L. giganteum* is distinct in character, having broad heart-shaped leaves and a noble stem 10 to 14 ft. high and bearing a dozen or more large, deflexed, funnel-shaped, purple-stained white flowers; *L. cordatum* (China and Japan) is similar in character, but shorter stemmed.

The cultivation of lilies is not difficult if the gardener keeps in mind a few essentials. Nearly all of them tend to die out in a few years and should therefore be replaced by fresh plantings. They are rich feeders and should only be planted in rich garden loam, with a layer of well-rotted manure well below the bulb but never touching it. Many species, notably *L. hansonii* and *L. henryi*, prefer partial shade to full sun. Drainage must be perfect because they will not stand stagnant water over the winter. If rodents (which eat the bulbs) are a pest, bulbs should be planted in underground wire cages.

In planting (except for *L. candidum*, which should be planted shallowly) the bulbs should be planted at least three times their height below the surface, so that stem roots which develop above the bulb will be in the soil. If a bulb is 3 in. high, its base, when planted, should be 9 in. below the surface. All lilies respond to a winter mulch of manure about 1½ in. thick. Tall sorts must be staked if the site is windy.

Other Lilies.—The Lent lily is a *Narcissus*; the African lily is *Agapanthus africanus*, the belladonna lily is *Amaryllis belladonna* (see **AMARYLLIS**); the Jacobean lily is *Sprekelia formosissima*; the mariposa lily is *Calochortus*; the Peruvian lily is *Astroemeria*; St. Bernard's lily is *Anthericum liliago*; St. Bruno's lily is

Paradisea liliastrum; the water lily is *Nymphaea*; the giant water lily of the Amazon is *Victoria regia*; the arum lily is *Zantedeschia aethiopica*; and there are many others, among them the day lilies (*Heimerocallis*).

See also references under "Lily" in the Index.

BIBLIOGRAPHY.—For the ancient and medieval history of the lily see M. de Cannart d'Hamale, *Monographie historique et littéraire des lis* (1870). Authorities for description and classification of the genus are J. G. Baker, "Revision of the Genera and Species of Tulipeae," *Journ. of Linn. Soc.*, 14:211 (1874), and H. J. Elwes, *Monograph of the Genus Lilium* (1880). The best sources on cultivation and varieties are H. M. Fox, *Garden Cinerellas* (1930); H. B. D. Woodcock and J. Coutts, *Lilies: Their Culture and Management* (1935); H. B. D. Woodcock and W. T. Stearn, *Lilies of the World* (1950); M. E. Leeburn, *Lilies and Their Cultivation* (1955); F. F. Rockwell et al., *The Complete Book of Lilies* (1961). See also the Royal Horticultural society's *Lily Year Book* (1947 et seq.). (N. Tr.)

LILY OF THE VALLEY

(*Convallaria majalis*), a beautiful plant of the lily family (Liliaceae), native to woods in some parts of England, Europe, northern Asia and possibly in the higher Allegheny mountains from Virginia to Tennessee, although the American plant is thought by some to be *C. montana*, an endemic species.

It is widely cultivated for its dainty, white, nodding, fragrant flowers, borne in spring on slender stalks, which, like the two oblong basal leaves, rise from an underground creeping stem, or rootstock. On these underground stems arise small detachable buds, commonly called pips. These, if planted about 1½ in. deep, preferably in the shade, represent the easiest way to start a planting and may also be forced for indoor blooms in winter. Variegated-leaved, double-flowered and pink horticultural varieties are available. (N. Tr.)

J. HORACE MCFARLAND CO.

LILY OF THE VALLEY (CONVALLARIA MAJALIS)

LIMA, a department in central Peru bounded on the southwest by the Pacific ocean, on the northwest by Ancash, on the northeast by Huánuco, Pasco, Junín and Huancavelica and on the southeast by Ica. The northeastern border of the department is drawn along the westernmost range of the Andes, which forms the continental divide. Area 13,087 sq.mi. Pop. (1961) 2,093,435. The capital is the city of Lima (pop. [1961] 1,774,596).

Along the coast there is seldom any rain at all. At Lima the average annual rainfall is 1.8 in., yet many years pass with no recorded rainfall. Temperatures along the coast are mild, averaging between 16° C. (61° F.) in August and 23° C. (74° F.) in February. Only where rivers descend from the Andes can there be irrigation. The five chief rivers—the Chancay, Huaura, Mala, Rímac and Cañete—are all short and only the last two, which rise in snow fields among the highest peaks, have a year-round flow of water to the ocean.

The coast is peculiar in that a thick cloud rests over it, especially from June to October. This cloud is in contact with the mountain slopes from about 2,500 ft. to 4,000 ft. above sea level and there, in the fog zone, is a lush growth of herbaceous annuals known as *loma*, on which cattle can be fed. Above the zone of *lomas* there is a regular rainy season from October to April.

Outside the great urban concentration of Lima and Callao (qq.v.) most of the people work as farmers and herders. Cattle destined for the market in Lima are driven up and down the mountain slopes to feed on the vegetation as it turns green with the rainy season or the fog season. The *lomas* provide pasture from June to October and the high mountain grasslands are green from October to April. From April to June cattle are fed on hay grown under irrigation. Other crops of the irrigated lowlands include

sugar cane, cotton and a variety of vegetables.

There is some fishing off Callao and Huacho, but not nearly so much as the wealth of fish life would support. Salt is produced from the evaporation of sea water at Huacho and Chilca. In the mountains there are copper mines at Casapalca, and coal mines at Oyón. The department is crossed from northwest to southeast by the Inter-American highway and is connected with the highland centres by both rail and highway.

(P. E. J.)

LIMA (a corruption of Rímac), capital and largest city of Peru and of the department of Lima, is situated on the Rímac river adjacent to its seaport Callao (q.v.). In the desert coastal zone, nearly 500 ft. above sea level, Lima is surrounded by an irrigated plain, out of which rise, here and there, rugged crystalline hills, among them San Cristóbal (1,343 ft.) just east of the city. Pop. (1961) 1,715,971.

Lima has grown enormously in area and in population in the 20th century and now covers more than 30 sq.mi. in a great triangle 8 mi. east and southeast of Callao and overlooking the Pacific. Most of the city lies south of the Rímac, the hilly terrain restricting growth on the north. This expansion has taken place on the great cone of alluvial deposition, the gentle slopes of which are truncated by the Pacific. In the pink cliffs so formed, the sand, clays and pebbles are evidence both of the plain's formation and of the fertility of the lands within and surrounding the city.

The climate is equable, the cool Humboldt current considerably reducing temperatures usually experienced in Lima's latitude. Winter temperatures rarely fall below 12° C. (54° F.) and those of summer seldom rise above 27° C. (80° F.). Rainfall averages between one and two inches annually, occurring in the form of sea mists from May to November. The long periods of overcast sky retard both insolation and radiation and prevent the extremes usually associated with desert climates.

History.—Lima was founded as the "City of the Kings" by Francisco Pizarro on Jan. 18, 1535, on the south bank of the Rímac. He traced the outlines of the chief plaza (Plaza de Armas) and the rectilinear plan of streets with built-up blocks and open plazas at intervals, a pattern which still survives. On the same day, he laid the cornerstone of the cathedral, consecrated in 1625, where his remains are preserved. The first archbishop was appointed in 1545. Lima became the luxurious capital of the Spanish viceroys, the first of whom arrived in 1544. By a grant from Charles V, the University of San Marcos, the first university in South America, was founded in 1551.

Lima thus became the focus of Spanish colonization in South America, the heart of Spanish power in the New World and the headquarters of the mercantile control system on the Pacific coast. As vast wealth from the mines accumulated, the city was embellished with elaborate balconies and carved stone portals, while churches and monasteries glittered with gold and silver. Stone bridges were built across the Rímac; one constructed in 1610 is still standing. Meanwhile, for protection against attacks by foreign pirates, the Duke of La Palata (viceroy 1681–89) built the city walls which stood until 1870, when they were razed and replaced by the present boulevards. Much of Lima was destroyed by an earthquake on Oct. 28, 1746, and little in the present city antedates that catastrophe.

During Latin America's struggle for independence Lima was the centre of Spanish resistance, and even after Peru's independence was declared (1821), the city remained rigidly conserva-

tive. The period of reconstruction was followed by a great influx of money from exploitation of the guano deposits on the coastal islands. This resulted in some public improvements, such as the railway to Callao (1851), a lighting system, and a water supply from the Andes. Following Peru's defeat by Chile in the War of the Pacific, Lima was occupied by a Chilean army from Jan. 17, 1881, to Oct. 22, 1883, and many public buildings and scientific, literary and artistic collections were pillaged.

The spectacular modern growth of the city, whereby it has spread over an area 15 times that of the old colonial town, is based on the rise of industry; the growth of its administrative, commercial and transportation functions; and a very large natural increase of its population. In addition it is estimated that 25,000 people immigrate into the capital annually from other parts of Peru. In the process of Lima's expansion south and west of its colonial nucleus, several settlements, such as Magdalena, Miraflores, Barranco and Chorrillos, have been absorbed, and Callao has become a part of Greater Lima.

Urban Regions and Principal Buildings.—The core of the old city, south of the Rímac, still remains the functional centre of the capital. Planned around the Plaza de Armas it includes the government palace, the national library, the city hall, the archbishop's palace, the cathedral and four of Lima's finest churches: La Merced, Santo Domingo, San Francisco and San Pedro. Within this part of the city are preserved many of the narrow streets of the original checkerboard plan, arcaded shops, shady parks and colonial houses with inner patios. Now, however, they share the heart of Lima with skyscrapers, modern banks, hotels, government office buildings and commercial offices. The 20-story skyscraper housing the ministry of education, immediately adjacent to the old University of San Marcos, dramatically symbolizes this curious blend of old and new. It also vividly emphasizes the fact that the advent of reinforced concrete has overcome the building restrictions formerly handicapping a city in an earthquake zone. The Torre Tagle mansion, now the Foreign office, with its fine wood carving and wrought ironwork, is the best remaining example of secular colonial architecture. Many of the churches also contain interesting relics of Peru's historic past. The church of San Pedro, for example, has the tombs of several viceroys, and its 16th-century bell was rung on the day that Peru's independence was declared. The old city nucleus, bounded by the Abancay, Tacna and Colmena avenues and the Rímac on the north, is also the communications centre of Lima; streetcar and bus lines radiate from it, and it is also the site of the Desembarados station of the Central railway, which adjoins the river. Each street in this section, several blocks long and known as a *jirón*, is named after one of the departments of Peru.

North of the Rímac there survives another part of old Lima, which was predominantly an area of aristocratic residences in the 18th and 19th centuries; many plaster-covered adobe houses with barred outer windows and flower-decorated balconies now line the streets. The Alameda de los Descalzos, at the foot of Cerro Cristóbal, a tree-shaded avenue laid out in 1610 and leading to the monastery of discalced friars, is a favourite promenade for the humbler citizens who now reside in this area north of the river.

At the southern limit of the old city is Plaza San Martín and, a short distance beyond, the circular Plaza Bolognesi, each containing a statue of the national hero for whom it was named. From these plazas radiate many wide concrete-paved avenues to the west and south, lined by delightful promenades. One of these, the Paseo Colón, 1 mi. long and 150 ft. wide, with a statue of Columbus, is bordered by trees, flowers and beautiful residences. At one end of this avenue is Exhibition park, 30 ac. of gardens, walks, artificial lakes, the national museum and a zoological garden.

The great arterial roads to the south spread out in a fanlike manner and reach the residential suburbs of San Isidro and Miraflores, with their modern villas, irrigated gardens and open spaces. Still other zones of residential expansion stretch toward the airport at Limatambo on the eastern fringe of the urban area and adjacent to the foothills of the sierra and the maize and cotton fields of the Lima plain.

The coastal districts of Magdalena, Barranco and Chorrillos at

FOTO BOOZ FROM "ANDEAN AIR MAIL AND PERUVIAN TIMES"

MINISTRY OF EDUCATION BUILDING
One of the tallest structures in Lima

the southern and southwestern extremities of the Lima urban area are examples of the "neighbourhood units" set up by the National Housing corporation. They are collective housing estates constructed of brick, cement and adobe accommodating many tens of thousands of Lima's middle-class citizens. On the seaward side extend the beaches and residential resorts which provide a recreational oasis for Lima's large population.

A relatively new feature, originating during the period after World War II, is the development of slum quarters in the northern foothills and along the Rimac terraces, consisting of shacks of every conceivable construction, known as *barriadas*. Many are inhabited by Indians from the sierra.

Cultural Institutions and Services.—The University of San Marcos has faculties of theology, law, medicine, arts and economics, and although some of its old buildings survive in the city centre, the new campus between Lima and Callao is a modern university city. There are also a Roman Catholic university; a school of engineering and mines; an agricultural college; military, naval and air academies; and a wide range of other educational institutions training students for commerce, teaching and arts and crafts. In addition to a well-developed state educational system of primary and secondary schools, there are schools of high reputation maintained by the British and American communities in Lima, along with many other private and convent schools.

Lima is well-endowed with museums, which include collections of Peruvian antiquities, arts, costumes and paintings of scenes and characters in national history. The Museum of the Republic is housed in a palace of the viceroys which was later the home of José de San Martín and Simón Bolívar, while the Museum of Anthropology and Archaeology contains a representative collection of the material culture of Peru's prehistory. The national library, founded by San Martín in 1821 and destroyed during the Chilean occupation of 1881–83, was razed by fire in 1943, destroying the library's valuable collection of some 120,000 volumes. A new building on the same site was opened in 1947. Learned societies include the national academy of medicine (1885); the Athenaeum, founded (1877) as a literary organization; the Historical institute (1905); and the Geographical society (1888), which includes a library, map room, museum and seismological observatory. The city is also an important publishing centre, and *El Comercio* (1839) is one of the oldest newspapers in South America.

Many of the city's parks provide athletic facilities, and in the Campo de Marte there is an auditorium used by the national symphony orchestra for public concerts. The national stadium, with a seating capacity of 70,000, is the nation's leading football arena, and country clubs, horse racing tracks and golf courses are other recreational facilities. Bullfighting is a popular spectator sport.

In the 20th century increasing attention has been paid to the provision of medical facilities, and modern social insurance hospitals of impressive size and design have been built in the city. There are also several hospitals maintained by charity and private organizations.

Trade, Industry and Finance.—Lima's acquisition of important industries is a development of the 20th century, and today the city has by far the largest industrial concentration in Peru, accounting for nearly 70% of the nation's industrial income. The industries are extremely varied, embracing woolen and cotton textiles, tanneries and factories producing leather goods, furniture, clothing, foods, beverages, and a great variety of consumer goods such as aluminum utensils, soap, cigarettes, glassware and silverwork. Foundries, cement works, motorcar assembly plants and oil refineries are also important.

Although there are isolated factories in the north and south of the city, most of the industrial sections of Lima lie in a five-mile band of territory between the capital and Callao. This permits them to utilize both the imports entering through the latter port and the labour supply of the metropolis, as the zone is served by three main roads and a railway. Oil-generated and hydroelectric power is relatively abundant for industrial development.

Nearly all commercial, banking and industrial firms involved in Peruvian business have their headquarters in the capital. The five principal banks are the Continental, Popular, Lima, National City

and Credit Bank of Peru, the three latter being supported by French, United States and Italian capital, respectively.

The city also dominates Peruvian communications. The airport at Limatambo is one of Latin America's finest and plays an important role in national and international links within the continent. About 60% of Peru's motor traffic is based in the capital, and Lima is the great consuming centre for most of the imports arriving by way of Callao. Its administrative, professional and religious functions also provide employment for a great proportion of its population.

The rapid growth of the city has confronted Lima with many grave problems, among which the more important are traffic congestion, especially in the heart of the city, inadequate housing accommodation, the provision of sufficient schools (20% of Lima's population is of school age) and increasing demands upon such urban facilities as water supply and public transport.

(G. J. B.)

LIMA, a city of northwest Ohio, U.S., is located on the Ottawa river (Hog creek), 79 mi. S.S.W. of Toledo; the seat of Allen county. The site was designated by state law in 1831, and its name was chosen by lot, the last to be drawn from a hat. It was incorporated in 1842.

Lima became the centre of the northwest Ohio oil fields in the 1880s and 1890s, especially after scientists discovered a commercially profitable method of removing the oil's sulfur content, and peak annual output once surpassed 20,000,000 bbl. As production diminished in the 20th century, Lima became the centre of a pipeline system operated by six major oil companies from fields in Wyoming, Texas and Oklahoma and supplying the Great Lakes and east coast.

Lima's factories manufacture machine tools, automotive engines, aircraft parts, power shovels and cranes, quarry and road-building equipment, cigars, electric and neon signs, enamelware, steel castings, school and highway buses, hearses, electric motors, rubber, petroleum products and chemicals. It is also the centre of a diversified agricultural area producing grain, soybeans, sugar beets, potatoes, and dairy, poultry and meat products. Nearby are Indian Lake, Lake St. Mary's and Ft. Amanda State parks. Pop. (1960) 51,037; standard metropolitan statistical area (Allen county) 103,691. For comparative population figures see table in OHIO: *Population*. (R. C. Do.)

LIMAN VON SANDERS, OTTO (1855–1929), German army officer famous for his services in Turkey, was born at Stolp (Slupsk) in Pomorze on Feb. 17, 1855. He entered the Hessian life guards in 1874 and rose to become lieutenant general commanding the Kassel 22nd infantry division in 1911. In 1913 he was made head of a German military mission to reorganize the Turkish army. In consequence of a Russian protest at his appointment to command the 1st Turkish army, he was made inspector general. Up to the outbreak of World War I in 1914, he did much to improve the Turkish army, which was in poor shape after the Balkan Wars.

In March 1915 Liman was sent to command the 5th Turkish army at Gallipoli (see DARDANELLES CAMPAIGN). With other Turkish commanders under him, he succeeded in holding the British and Australians and ultimately causing them to evacuate the peninsula. Later, in March 1918, he commanded the 4th, 7th and 8th Turkish armies in Syria and Palestine and for a time held up the British advance. He withdrew most of his forces to Aleppo. After the armistice, he was for a time interned in Istanbul but then organized the repatriation of the German soldiers serving in Turkey. He spent his last years in retirement in Germany and died in Munich on Aug. 22, 1929. Gen. Sir Ian Hamilton, his opponent at Gallipoli, described him as a "clean fighter and a generous foe." He published *Fünf Jahre in Türkei* (2nd ed., 1922; Eng. trans. 1927). (M. P. P.)

LIMASSOL (Gr. *LEMISOS*), a port of Cyprus on Akrotiri bay on the southern coast, lies about 85 km. (53 mi.) S.W. of Nicosia by road. Pop. (1960) 43,593. The sea front is lined with hotels and tourist and customs offices. There is a pier and small dock for vessels under ten-foot draft. Larger ships are served by lighters (barges). Behind the sea front are law courts, banks, municipal

offices, churches, shops and houses. Features of interest include a 100-bed hospital (1957), a housing estate, public gardens with a zoo and the Curium Palace hotel. Limassol castle, now a museum, is chiefly 15th century but has traces of many architectural periods. Limassol is connected by road with the rest of the island.

The chief products are carob, wine, raisins, asbestos and chrome. Bricks, tiles, buttons and soft drinks are manufactured, and fruit is canned. There are umber mines in the district. West and southwest of Limassol are the British military base of Episkopi and the Royal Air Force (R.A.F.) base of Akrotiri in a small enclave of British territory.

The ruins of Amathus (old Limassol), an early Phoenician settlement, are situated 8 km. (5 mi.) E., and Curium, 14 km. (9 mi.) W., was once a flourishing Mycenaean colony. In Roman times Limassol (Lemessus) was the capital of one of the four divisions of Cyprus. It was there that Richard I Coeur-de-Lion landed in 1191 and was married to Berengaria of Navarre. The emperor Frederick II landed at Limassol in 1228 with a claim to the regency of Cyprus. The castle was the first in Cyprus to be captured by the Turks when they took the island from the Venetians in 1570. Limassol was an important trading centre under the Turks and British and remains so in independent Cyprus. (M. Ro.)

LIMBE: see BLANTYRE-LIMBE.

LIMBO (LIMBUS), in Roman Catholic theology, denotes the border of hell, where dwell those who, while not condemned to torture, are deprived of the joy of heaven. In medieval theology there are (1) the *limbus infantum* and (2) the *limbus patrum*.

The *limbus infantum* or *puerorum* is the abode to which human beings dying without actual sin, but with their original sin unwashed away by baptism, were held to be consigned; the category included not unbaptized infants merely but also the mentally defective. The word "limbus," in the theological application, occurs first in the *Summa* of Thomas Aquinas; for its extensive currency it is perhaps most indebted to Dante. The question as to the destiny of infants dying unbaptized presented itself to theologians at a comparatively early period. Generally speaking it may be said that the Greek Fathers inclined to a cheerful and the Latin Fathers to a gloomy view. Indeed, some of the Greek Fathers expressed opinions which it is almost impossible to distinguish from the Pelagian view that children dying unbaptized might be admitted to eternal life, though not to the Kingdom of God. In his recoil from Pelagian heresy, Augustine was compelled to sharpen the antithesis between the state of the saved and that of the lost; thus he taught that there are only two alternatives—to be with Christ or with the devil, to be with him or against him. Later theologians and schoolmen followed Augustine in rejecting the notion of any final position intermediate between heaven and hell but otherwise inclined to take the mildest possible view of the destiny of the irresponsible and unbaptized.

The first authoritative declaration of the Latin Church upon this subject was that made by the second Council of Lyons (1274) and confirmed by the Council of Florence (1439), with the concurrence of the representatives of the Greek Church, to the effect that "the souls of those who die in mortal sin or in original sin only forthwith descend into hell, but to be punished with unequal punishments." The damnation of infants and also the comparative lightness of the punishment involved in this are thus *de fide*; but nothing is determined as to the place they occupy in hell, as to what constitutes the disparity of their punishment or as to their condition after the day of judgment. In the Council of Trent there was considerable difference of opinion as to what was implied in deprivation of the vision of God, and no definition was attempted. Some theologians continue to maintain with Robert Bellarmine that the infants "in limbo" are affected with some degree of sadness because of a felt privation; others hold that they enjoy every kind of natural felicity, as regards their souls now and as regards their bodies after the resurrection, just as if Adam had not sinned.

The *limbus patrum* or *sinus Abrahæ* ("Abraham's Bosom"; Luke xvi, 22) is defined in medieval theology as the place in the underworld where the saints of the Old Testament were confined until liberated by Christ on his "descent into hell." Regarding

the locality and its pleasantness or painfulness nothing has been taught as *de fide*. It is sometimes regarded as having been closed and empty since Christ's descent, but other authors do not think of it as separate in place from the *limbus infantum*. The whole idea has been described as the mere *caput mortuum* of the old doctrine of Hades (the place of waiting, of "the spirits in prison"; I Pet. iii, 19), which was gradually superseded in the Roman Church by that of purgatory (*q.v.*).

LIMBURG (LIMBOURG), **POL, HERMAN, AND JE-HANEQUIN DE** (active c. 1400–1416), most famous of all medieval book illuminators, were born in the Netherlands but achieved fame in Paris. The sons of a sculptor, Arnold van Limburg, they were also the nephews of Jean Malouel, court painter to the duke of Burgundy, and are sometimes known by the name "Malouel" (various spellings). The brothers worked together, and although the eldest and most celebrated appears to have been Pol it has never been possible to distinguish their individual styles. All three died, presumably during an epidemic, in 1416.

About 1400 the brothers were apprenticed to a goldsmith in Paris, and between 1402 and 1404 Pol and Jehanequin were working for the duke of Burgundy in Paris, possibly on the illustration of a *Bible moralisée* now in the Bibliothèque Nationale, Paris. Some time after Burgundy's death in 1404, however, they entered the service of his brother, the duke of Berry, and it was for him that their most lavishly illustrated Books of Hours (the popular form of private prayer book of the period) were produced: the *Belles Heures* (or *Les Heures d'Ailly*, now in The Cloisters, New York) and the *Très Riches Heures* (Musée Condé, Chantilly, France). The latter was left unfinished in 1416 and was completed c. 1485 by Jean Colombe, but the sequence of early 15th-century miniatures are among the supreme examples of the International Gothic style. It is essentially a court style, elegant and sophisticated, combining naturalism of detail with overall decorative effect. An awareness of the most progressive international currents of the time, particularly those deriving from Italy, suggests that at least one of the brothers visited there. Panel paintings, notably a female portrait in the National Gallery of Art, Washington, D.C., are among works attributed to one or another of the Limburgs.

LIMBURG (Fr. LIMBOURG), the most northeasterly of the nine provinces of Belgium, consists of 3 administrative *arrondissements* (Hasselt, Maaseik and Tongeren), 13 judicial cantons and 206 communes. Pop. (1961) 574,606. Area 2,422 sq.km. (935 sq.mi.).

Except for the small Maastricht territory in the Netherlands, Limburg is bounded on the east by the Meuse river. The province divides into three physical regions: the eastern Kempenland plateau in the north, the Demer valley and, in the south, part of the plateau of Hesbaye.

The Kempenland, a plateau between the incised valleys of the Meuse and Demer, is covered by superficial deposits of Quaternary sands and gravels of fluvial origin, laid down by the Meuse in postglacial times when it was swollen and heavily laden. These overlie a mass of Pliocene and other late Tertiary sands. The surface consists of gentle eminences, separated by shallow marshy depressions. The plateau forms a broad indeterminate watershed (maximum altitude, 330 ft.) between streams that drain northward to the lower Meuse and southward to the Demer. It is characterized by sands, often blown into dunes, and has heathland vegetation in the bleaker moorlands, developed where waterlogging has been caused by an underlying impervious hardpan.

The broad Demer valley lies along the southern edge of the plateau; the river meanders westward to join the Dyle, picking up headstreams from both north and south. It has been regularized, and the flat alluvium-covered floor is crossed by a maze of cutoffs and artificial drainage channels.

The southern part of Limburg consists of part of the low

plateau of Hesbaye, with Oligocene sands and clays covered with *limon*. The plateau slopes gently northward to the Demer furrow, crossed by its many tributaries.

The Kempen plateau has coarse sandy soils supporting scanty agriculture, despite much reclamation. Small areas of rye, potatoes and fodder beet are cultivated near villages, pastures are sown with drought-resistant grasses and about a quarter is covered with plantations of Scots and Corsican pine. The Demer valley, with its damp alluvial soils, has dairy farming, and along its margins, between Diest and Hasselt, market gardening is prosperous. Northern Hesbaye, with its sandy loams, has mixed agriculture, including wheat and sugar beet, vegetable-growing and fruit cultivation, as near Tongeren (French, Tongres). Nearly half the province is under arable crops, and nearly a quarter of all Belgian fruit cultivation is found there. The heathlands are grazed by large flocks of sheep, cattle and pigs.

Settlements in the sparsely populated Kempen are on the plateau edges and in the Meuse and Demer valleys. The regional centre is Hasselt (*q.v.*; pop. [1961] 36,618), in the Demer valley, an administrative centre, with a variety of industries—flour mills, distilleries, tobacco factories, breweries, a gelatin works, brickworks, timberyards, tanneries, glue works and fertilizer factories. Farther south are Sint-Truiden (French, St. Trond; pop. [1961] 20,776), an important strategic position, and Tongeren (pop. [1961] 16,176), with local food-processing industries.

Limburg is underlain by the "concealed" Kempen coal field, where coal was discovered in 1901 and first raised commercially in 1917. Its collieries produce nearly one-half of Belgium's coal. A third of the miners are of foreign origin. The commune of Genk (*q.v.*; pop. [1961] 47,416) has three collieries. Zinc and other nonferrous refineries and chemical works are located on cheap, spacious heathland sites.

The needs of industry involved the construction of new roads, railways and tramways and the Albert canal between Antwerp and Liège. Two railway lines cross the province from west to east: from Antwerp via Mol to Mönchengladbach, Ger.; and from Antwerp via Hasselt to Maastricht. The main south-north line is Leuven (Louvain)—Turnhout—Tilburg—Utrecht. For history see LIMBURG, DUCHY OF. (F. J. M.)

LIMBURG, the southeasternmost province of the Netherlands, is bounded north by Gelderland, northwest by North Brabant, south and southwest by the Belgian provinces of Limburg and Liège and east by Germany. Area 2,251 sq.km. (869 sq.mi.). Pop. (1962 est.) 911,568. The southern part, extending to Sittard, consists of a plateau of Cretaceous rocks, sloping downward from the south (near Vaals is the highest part of the Netherlands, 1,054 ft.) to the north, intersected by the Geul and Gulp rivers and covered with loess. There is a coal field underneath some parts of this plateau. In the rest of the province the soil consists mainly of Pleistocene sands. The province is watered by the Maas (Meuse), which forms part of its southwestern boundary and then flows through its northern portion, and by tributaries like the Geul and the Roer.

There is coal mining around Heerlen, Kerkrade and Geleen. At Geleen there is a large chemical works. Coal is shipped from the river ports of Bonn and Stein. The chief industrial centre is Maastricht, the provincial capital, where glass, porcelain, paper, cement, rubber and chemicals are produced and printing is carried on.

Although the loess plateau has fertile arable ground for the cultivation of wheat, rye and sugar beet, dairy farming is increasing as a result of the large increase in population. There is much fruitgrowing, especially cherries.

In the sandy regions farming is mixed, although there is more arable land (mostly producing rye). Pigs and poultry production are important, Roermond having the largest egg market in the Netherlands. Venlo is the centre of a market-gardening area exporting to Germany. Industry is mainly concentrated in the larger centres, such as Roermond, Weert, Venlo and Sittard, and includes light-metal, clothing, hosiery and chemical works and flour mills. The region east of the Meuse between Venlo and Roermond is an important brick- and tilemaking district. For history see LIMBURG, DUCHY OF. (H. J. KE.)

LIMBURG, DUCHY OF, a historic territory of the Low Countries, whose name survives in that of the two provinces of Limburg, one belonging to the kingdom of Belgium, the other to the kingdom of the Netherlands.

When Walram II, count of Arlon, married Judith, daughter of Frederick of Luxembourg, duke of Lower Lorraine (d. 1065; see LORRAINE), he received from his father-in-law some lands lying on either side of the Meuse river and proceeded to build a castle at Limburg. The castle stood on the Vesdre river east of Liège and southwest of Aachen, and from it he took the title of count of Limburg (as Walram I). His son Henry I of Limburg (d. 1119?) was invested as duke of Lower Lorraine by the Holy Roman emperor Henry IV in 1101 but was removed from that dignity by Henry V in 1106 and fell into the hands of the new duke, Godfrey the Bearded of Louvain (d. 1139). This Godfrey, however, was in turn deposed from the duchy in 1128 in favour of Henry I's son Walram II of Limburg, but after the latter's death (also 1139) the duchy of Lower Lorraine, or Lothier as it was now called, was restored to Godfrey II of Louvain (d. 1142). Walram II's son Henry II of Limburg (d. 1167) failed to wrest the title of duke of Lothier from Godfrey III of Louvain and finally gave him his daughter Margaret in marriage (1155), contenting himself with the title of duke of Limburg. The emergence of this new duchy marks the end of Lower Lorraine or Lothier as a real entity: Godfrey III's successor in 1190, Henry I of Louvain, styled himself duke of Brabant (*q.v.*).

With Henry II's successors in Limburg, namely Henry III (d. 1220), Walram III (d. 1226), Henry IV (d. 1246 or 1247) and Walram IV (d. 1279 or 1280), the direct male line of the house of Arlon came to an end. After the death of Walram IV's daughter Irmgard (1282 or 1283), the War of the Limburg Succession broke out, since her cousin Adolf V of Berg disputed the right of her widower, Reinald I of Gelre (see GELDERLAND), to remain in possession of the duchy. Adolf sold his rights to John I of Brabant, and most of the neighbouring states became involved in the struggle: Holland, Jülich, Cleves and the city of Cologne took John's side; Flanders, Nassau and Archbishop Siegfried of Cologne took Reinald's. Reinald eventually sold his own rights to Henry III of Luxembourg; but in the battle of Woeringen or Worringen (June 5, 1288), John won the duchy of Limburg for Brabant.

The duchy of Limburg at this time comprised the bailiwicks of Hervé, Montzen, Baelen, Sprimont and Wallhorn and the counties of Rolduc, Daelhem and Falkenberg. In personal union with Brabant, it conserved its separate institutions. In 1396 the widowed duchess Joan of Brabant ceded it to her niece Margaret of Flanders, wife of Philip the Bold, duke of Burgundy, whose second son Anthony succeeded to it in 1404, two years before he became duke of Brabant also. On the death of Anthony's son Philip (1430) Limburg and Brabant were united with the rest of the Netherlands under Philip the Good, duke of Burgundy. In 1482 Limburg passed to the house of Habsburg with the Burgundian inheritance (see NETHERLANDS, THE: History). Maastricht was attached to Limburg in 1530.

In the latter phases of the war between the United Provinces of the Netherlands and the Spanish Habsburgs, the Dutch conquered the northern part of Limburg; and at the peace of Westphalia (1648) Daelhem, Falkenberg and Maastricht were ceded to them, to become one of the so-called "Generality lands" under the joint rule of the states-general. Southern Limburg passed with the rest of the Spanish Netherlands to the Austrian Habsburgs under the peace of Rastatt at the end of the War of the Spanish Succession (1714). Annexed by the French in 1795 and divided between the *départements* of Ourthe and Meuse-Inférieure, Limburg was reconstituted as a province of the new kingdom of the Netherlands in 1815. This province, however, comprised not only the old duchy but also a piece of Gelderland and the county of Loos.

At the Belgian revolution of 1830 all Limburg except Maastricht took the Belgian side (see BELGIUM: History); and so long as William I of the Netherlands refused to recognize the London treaty of Oct. 1831, the province remained, together with Luxembourg, under Belgian occupation and sent its representatives to

Brussels. At last, in 1838, William decided to accept the treaty, and in April 1839 Belgium accordingly had to renounce parts of Limburg and of Luxembourg. That part of Limburg which lay on the right bank of the Meuse, together with Maastricht and a number of communes on the left bank (including a large area in the north), then became a sovereign duchy under the rule of the king of the Netherlands; but in order to compensate the German confederation for the loss of its rights over the part of Luxembourg which Belgium was allowed to retain, the duchy of Limburg (apart from the communes of Maastricht and Venlo) was declared to belong to the confederation, as did the rest of Luxembourg. When the German confederation had been dissolved after the Seven Weeks' War (1866), a conference met in London to consider the Luxembourg-Limburg question; and in 1867 it was decided to sever all connection of the two duchies with Germany. Thereafter eastern Limburg was integrated with the Netherlands, though the province continued to be described officially as a duchy till 1906. Belgian attempts to secure the cession of eastern Limburg after World War I, chiefly on the grounds that the Germans had been able to violate Dutch neutrality to Belgium's disadvantage during the war, were overruled by the peace conference of Paris in 1919.

BIBLIOGRAPHY.—S. P. Ernst, *Histoire du Limbourg* (1837–52); P. C. Boeren, *De Oorsprong van Limburg en Gelre* (1938); H. A. Beaujean, *Geschiedenis van Limburg* (1949); G. Poswick, *Les Délices du duché de Limbourg* (1951).

LIMBURGITE, a dark-coloured volcanic rock resembling basalt in appearance, but normally containing no feldspar. The name is taken from Limburg (Germany). It consists essentially of olivine and augite with a brownish glassy ground mass, in which a second generation of small augites frequently occurs; more rarely olivine is present also as an ingredient of the matrix.

The principal accessory minerals are titaniferous iron oxides and apatite, and in some limburgites large phenocrysts of hornblende and biotite are found; in others large crystals of sodalite or anorthoclase. Hauynite, a variety of sodalite (*q.v.*), is an ingredient of some of the limburgites of the Cape Verde Islands. Rocks of this group occur in considerable numbers in Germany (Rhine district) and in Czechoslovakia (Bohemia), also in Scotland (Whitelaw hill, Haddington), France (Auvergne), Spain, Africa (Kilimanjaro), Brazil, etc. They are associated principally with basalts, nephelite- and leucite-basalts and monchiquites. From the last-named rocks the limburgites are not easily separated as the two classes bear a very close resemblance in structure and in mineral composition. The ground mass of the monchiquites is not a glass, however, but crystalline analcite (*see* LAMPROPHYRE). Limburgites may occur as flows, as sills or dikes, and are sometimes highly vesicular.

LIME. The tree and fruit of the species *Citrus aurantifolia*, widely grown for its acid fruits throughout the tropical and subtropical areas of the world. The native home of the tree is believed to be the East Indian archipelago and perhaps the nearby mainland of Asia. (In England "lime" is also used to designate the basswood tree or linden; *q.v.*) The Arabs are believed to have taken limes, as well as lemons, from India to the eastern Mediterranean countries and Africa around A.D. 1000 or possibly earlier. Limes were introduced to the western Mediterranean countries by returning crusaders in the 12th and 13th centuries A.D. Columbus took citrus fruit seed, probably including limes, to the West Indies on his second voyage in 1493 and the trees soon became widely distributed and partially naturalized in the West Indies, Mexico and Florida.

Plant Characteristics.—The tree seldom grows more than 8 to 15 ft. high and if not pruned becomes shrublike. Its branches spread and are irregular, with short stiff twigs, small leaves and an abundance of small, sharp thorns. The leaves are pale green; the small white flowers are usually borne in clusters. The fruit is $1\frac{1}{2}$ to $1\frac{3}{4}$ in. in diameter, oval to nearly globular, often with a small apical nipple; the peel is thin, and greenish-yellow when the fruit is ripe. The pulp is tender, juicy, yellowish-green in colour and decidedly acid. As a group, limes somewhat exceed lemons in both acid and sugar content. There are, however, some varieties so

lacking in citric acid that they are known as sweet limes. These are grown to some extent in Egypt and other tropical countries.

Varieties and Hybrids.—The two general groups of acid limes are the Mexican and the Tahiti. The Mexican group is characteristic of the species *C. aurantifolia*, described above. Several varieties, including Everglade and Yung, have been named but in general differ but little from each other. Numerous thornless strains of Mexican limes have arisen from seedlings and from bud sports.

The trees of the Tahiti group resemble the lemon and are larger and more vigorous than those of the Mexican group, with leaves larger and darker coloured. The fruit is larger and more elongated than the Mexican lime; the peel is thicker and the fruit nearly seedless.

The flavour of the fruit of the two groups is similar, but the Tahiti lime lacks some of the bouquet which is typical of the Mexican. The Tahiti lime so closely resembles a lemon that the fruit could easily be confused except for the colour of the pulp and the distinctive taste. From the appearance of the Tahiti group there seems to be a possibility that this fruit may be a hybrid between the lemon and the typical Mexican lime. Leading varieties of the Tahiti group are Bearss, Pond and Tahiti, also called Persian.

The lime hybridizes readily with other species of citrus and some closely related genera. Some of these hybrids are grown as novelties and, to a limited extent, commercially. The Perrine lemon, a cross of Mexican lime and Genoa lemon, is grown locally in Florida and warmer parts of Louisiana and Texas. The limequats, crosses of limes and kumquats, are hardier and more disease resistant than limes and are grown in areas slightly too cold for limes or lemons. Hybrids of limes and mandarin oranges are acid fruits grown locally and also used to some extent as rootstocks for the propagation of other kinds of citrus.

Production and Use.—Mexico is a leading country in lime production, producing around 2,000,000 boxes per year. Egypt produces about 1,000,000 boxes annually, but some estimates are much higher. From 300,000 to 400,000 boxes per year are produced in the United States, mainly in southern Florida. Limes are grown throughout the West Indies and to a limited extent in practically all citrus-growing areas. The trees are a little less cold resistant than most kinds of citrus, so production is largely restricted to relatively frost-free locations.

Limes are used mainly for flavouring drinks, food and confections, much as are lemons. Limeade and other lime-flavoured drinks have a flavour and bouquet quite distinct from those made from lemons. The juice may be concentrated, dried, frozen or canned in a manner similar to lemon juice.

The yield of fresh juice depends upon the variety and the condition of the fruit and varies from 60 to 90 gal. per ton of fruit. The small Mexican lime is less readily handled by machinery in the reaming process than are the larger varieties. Limes contain vitamin C (ascorbic acid) and were formerly used in the British navy to prevent scurvy (hence the nickname "Limey"). Lime oil is a by-product of the fruit, the chief centre for its production being the West Indies. Citrate of lime and citric acid are also prepared from it.

Methods of culture, propagation and pest control for limes are comparable to those used in other citrus orchards. *See* also LEMON and ORANGE.

Webber, "Cultivated Varieties of Citrus," vol. 1, chap. v, in *The Citrus Industry* (1943); W. H. Chandler, *Evergreen Orchards*, 2nd ed., chap. 3, pp. 148–51 (1958). (J. R. MAG.)

LIME. In the strict chemical sense lime refers only to calcium oxide (or quicklime); however, lime which is commercially manufactured from limestone is rarely produced in the pure state and the presence of other substances gives rise to different types of limes having commercial importance. High-calcium limes, chiefly used for various chemical and industrial purposes, are produced from calcareous materials (generally limestone but also chalk and oyster shells) containing 95% to 99% calcium carbonate. Lime-

stones containing various proportions of magnesium carbonate are widely found and are also used to make lime. Magnesium limes are produced from stones containing magnesium carbonate in excess of 5%. One magnesium lime of special importance is dolomitic lime, produced from the mineral dolomite, a type of limestone containing from 30% to 45% magnesium carbonate (see CALCITE; DOLOMITE; LIMESTONE). In the U.S. only limes made from high calcium and dolomitic limestones have commercial significance.

In common usage the term lime includes the various chemical or physical forms of quicklime, hydrated lime and hydraulic lime. When limestone is heated under controlled calcination conditions, the carbonates decompose, producing quicklime. Commercially, quicklime is commonly produced by burning carefully graded limestone in rotary kilns, similar to those used in portland cement manufacture, and in large stationary vertical kilns. The by-product carbon dioxide gas is generally permitted to escape from the kilns, though sometimes it is collected and used to manufacture precipitated calcium carbonate, dry ice, etc. Quicklime, as it is normally manufactured, is highly reactive; however, when calcined for a prolonged time at elevated kiln temperatures, the porous structure contracts. The material loses its chemical reactivity and the lime is said to be "dead-burned." Some dolomitic limestone is commercially processed in this manner; it is known as dead-burned dolomite and is widely used as a lining for basic open-hearth steel furnaces.

When quicklime reacts with water the process is called slaking; the reaction is exothermic, and proceeds at times with almost explosive violence. Dry hydrated lime is produced when quicklime is reacted with just sufficient water to satisfy its chemical affinity for moisture under the conditions of hydration. High calcium quicklimes react readily with water; on the other hand, dolomitic quicklimes, because of the less reactive magnesium oxide component, do not hydrate completely in ordinary processing equipment.

Dolomitic limes hydrated in equipment operated at atmospheric pressures and low retention times are known as dolomitic normal hydrated limes and essentially consist of calcium hydroxide and magnesium oxide with a small quantity of magnesium hydroxide. The magnesium oxide portion of dolomitic lime along with the calcium oxide can be hydrated completely in special equipment using longer retention periods or elevated pressures and temperatures. These "pressure hydrated" or highly hydrated limes are commercially known as dolomitic special hydrated lime.

Hydraulic lime is a type of cementitious lime that will set and harden under water in a manner similar to portland cement. It is obtained by calcining an impure limestone containing large quantities of silica and alumina so that sufficient calcium silicates and aluminates are formed to give the lime its characteristic hydraulic properties. Hydraulic limes are widely used in Europe for mortars in masonry construction; use in the United States, however, is limited.

Limes vary considerably in chemical and physical properties. In part this is due to differences in geology and chemical analyses of the raw limestone. More markedly, however, the degree of overcalcination and other processing variables and conditions affect the rate of slaking, plasticity, density and chemical reactivity of the limes produced. Both quick and hydrated limes are usually white in colour, though some grayish impure limes are known. Calcium and magnesium hydroxides are only slightly soluble in water; nevertheless, the term lime water denotes a weak aqueous solution. Milk of lime is a suspension of lime solids in water.

Lime is widely used to neutralize acids; on the basis of neutralizing values, quick and hydrated limes are stronger bases than sodium hydroxide and sodium carbonate.

Uses.—Next to sulfuric acid, lime was the most widely used chemical in industry in the second half of the 20th century, and was the leading alkali in tonnage consumed. Both quick and hydrated lime products find extensive application in the agricultural, building and chemical industries. Formerly lime was considered primarily a building and agricultural material, and in many un-

developed parts of the world applications for lime are still largely confined to these fields. However, lime is employed basically as a chemical in industry. In the U.S. alone three-fourths of the annual lime tonnage is consumed industrially. Chemical lime is consumed in large quantities by the metallurgical industry in the manufacture of open-hearth and electric-furnace steel, production of magnesium, treatment of aluminum, gold and silver ores, and the smelting and refining of copper, zinc and other metals. Dead-burned dolomite is extensively used as a refractory material to line high-temperature kilns and furnaces. Large quantities of lime are required in the manufacture of paper, calcium carbide and glass, as well as in the purification of water supplies and in the treatment of sewage and industrial wastes. Other chemical applications are in sugar and petroleum refining and in the manufacture of sand-lime brick and concrete products, insecticides, leather goods, bleaching powder, sodium hydroxide, varnish and paints, grease and other products. A market for lime was also developed as a soil-stabilizing agent in the construction of base courses for modern highways and airport runways.

In agriculture, lime—not to be confused with pulverized limestone—is one of several soil liming materials used for promoting crop production by correcting soil acidity and furnishing important plant nutrients.

History.—Lime is one of the oldest products known to man, dating possibly as far back as the cave-man era and the discovery of fire. Primitive kilns which are believed to have been used for preparing lime during the Stone Age have been excavated. It is certain that lime was the first manufactured chemical used by mankind, probably the first agricultural material employed for soil fertility, and certainly one of the oldest mortar and plastering building materials known. Virtually every civilization has utilized lime. Lime plaster, still in good condition, has been found in some pyramids built more than 4,500 years ago in Egypt. The Old and New Testaments of the Bible mention lime several times. Lime was extensively used in mortars and plasters by the Greeks, Romans, Arabians, Moors and other Mediterranean cultures. It was also used by the Incas and Aztecs in South and Central America and by the Chinese in constructing their Great Wall. The first mention of lime as a chemical reagent was by the Roman Xenophon, who recorded that ships carrying a cargo of linen and lime (for its bleaching) were wrecked in 350 B.C. near Marseilles. And another Roman, Vitruvius, an architect under Augustus, wrote the first detailed lime specification. The Romans also used lime in building the road base of the famous Appian way. The Romans originated cement (hydraulic lime), which they prepared from mixtures of lime putty and volcanic ash. Old relics and records in England indicate that lime was used as a mortar material during the Roman occupation. Lime plastering and stuccoing reached their peak during the Italian Renaissance; and during the same period Michelangelo, Raphael and other famous artists created their mural and fresco masterpieces using lime putties extensively. (See also FRESCO PAINTING.)

In North America lime was probably first used by the Spaniards in Florida in the 16th century. Tabby construction consisting of oyster-shell lime, sand and crushed shells was employed for building walls. Early Spanish missions in California and the southwest were invariably constructed of lime stucco. As early as 1635 in Rhode Island quicklime was produced from limestone; however, the Pilgrims probably burned lime from shells at an earlier date shortly after settling at Plymouth, Mass. Lime manufacturing first became a significant industry in commerce about 1733, when boats were used to ship lime from Rockland, Me., to Boston, Mass. Technical progress since the beginning of the 20th century markedly advanced lime manufacturing to its modern important industrial position.

See LIMING; MORTAR IN BUILDING; see also references under "Lime" in the Index. (K. J.)

LIMEHOUSE, a district in the Stepney area of Tower Hamlets (*q.v.*) Borough of the East End of London, Eng., lies on the north bank of the River Thames. It has a large population of workers employed in the nearby West India and East India docks, and of sailors, both natives of London and foreigners, off

merchant ships temporarily in port. There are several homes and hostels for seamen in the area. The Limehouse Cut, a channel which connects the Lea with the Thames, was opened in 1770. St. Anne's, the parish church, completed in 1724 and consecrated in 1730, was designed by Nicolas Hawksmoor, a pupil of Sir Christopher Wren. It was partially destroyed by fire on Good Friday, 1850, and finally reopened after restoration on April 26, 1857. West India Dock Road, with Limehouse Causeway and Pennyfields (in Poplar), is the centre of the much-reduced Chinese quarter. In Narrow Street, the western continuation of Limehouse Causeway, stands "The Grapes" riverside public house, said to be the original of "The Six Jolly Fellowship Porters" in Charles Dickens' *Our Mutual Friend*. Another well-known public house in the area is "Charley Brown's," a resort for sailors with a collection of world curios. The name Limehouse is probably a corruption of the original Lymehostes, which referred to the lime oasts or limekilns in the district. (HE. WA.)

LIMERICK, THOMAS DONGAN, 2ND EARL OF (1634–1715), colonial governor of New York, was born at Castletown, County Kildare, Ireland. The Dongan family went into exile with other Stuart supporters in 1649, and young Thomas entered an Irish regiment of the French army and by 1674 reached the rank of colonel. He was recalled to England in 1677, granted a pension of £500 and appointed lieutenant governor of Tangier (1678–80). In 1682, the Duke of York named him governor of the colony of New York. He was an unusually competent official and left a lasting imprint on the history of New York and other American colonies. He called the first representative assembly in New York and espoused a very liberal "Charter of Liberties" and a broad tolerance in religious matters. His territorial ambitions for New York were practically boundless, but his aggressive policy did result in fixing the boundaries between New York and the other English colonies and later with Canada. Dongan must be given credit for seeing the importance of the position of New York and of the Iroquois tribes in the international struggle for North American supremacy. He carried on his vigorous policy against the French in America despite the fact that his masters in Europe, the Duke of York and Charles II, were allied with Louis XIV and despite French-Canadian appeals to his religious sympathies as a Roman Catholic. James II tardily sanctioned Dongan's French and Indian policy, and many years later the treaty of Utrecht vindicated it by acknowledging the Iroquois as British subjects and Lake Ontario as the boundary of New York.

In 1683 during the period of colonial consolidation, Dongan was relieved of the governorship. He returned to England in 1691, succeeded his brother as earl of Limerick in 1698, and died in London on Dec. 14, 1715. His last years were spent unsuccessfully in trying to recoup his fortune by regaining title to his family lands in Ireland, by collecting the arrears on his pension, and by receiving payment for his personal expenditures for the expansion of New York.

See J. H. Kennedy's *Thomas Dongan, Governor of New York (1682–1688)* (1930) and E. Channing's "Colonel Thomas Dongan, Governor of New York" in *Proceedings of the American Antiquarian Society*, vol. xviii, pp. 336–345 (1906–07). (RA. MU.)

LIMERICK (LUIMNEACH), a county of the Republic of Ireland in the province of Munster, covers 1,037 sq.mi. and has a population (1961) of 133,339. All of its northern boundary is the Shannon estuary and river, except at the city of Limerick, where an area north of the river has been included because of suburban growth. The river Maigue bisects the county and flows north into the Shannon. On the west the Kerry boundary runs through Carboniferous uplands, plateaus mainly 1,000–1,200 ft. high with unproductive Coal Measures, and on the east the boundary with Tipperary runs from the Shannon to Slievefelim (1,524 ft.), then across the Golden vale southward to the Galtee mountains, to the summit of Galtymore (3,018 ft.). The southern boundary, with Cork, follows the Ballyhoura hills, a continuation of the line of the Galtees. These uplands, the Slievefelim, the Galtees and the Ballyhouras, are mainly formed of Devonian (Old Red) Sandstones.

Lowland Limerick is in the main a rolling hummocky landscape

with a variety of glacial drifts, 150–350 ft. high. It is diversified by a number of hills, partly formed of igneous rocks, which rise to 612 ft. near Ballingarry. There are also a number of isolated volcanic hills, including several a few miles south of Limerick city: of these, one of the most striking is Carrigogunnel, a fine crag rising above the Shannon "slob lands," or floodplain. It is crowned by a medieval castle. At one time parts of the lowland were covered with peat bog, but virtually all this has been removed, and pastoral farming gives unity to the scene. The farms are mainly of medium size, from 50 to 80 ac.

The area formed part of the old kingdom of Desmond. With the coming of the Anglo-Norman invaders, it fell largely to the FitzGerald, created earls of Desmond in 1329. For a while their headquarters were at Kilmallock in the southeast of the modern county and later at Askeaton. With the downfall of the earls of Desmond, a large part of county Limerick fell within the scope of the plantation of Munster, begun in 1586. Later changes in land ownership occurred in Cromwellian times. Early in the 18th century some German settlers came from the Palatinate and they were still a recognizable community in the 1830s but have since merged with the general population.

There are remains of round towers at Ardpatrick and at Dysert, and of stone circles, pillar stones and altars at Lough Gur where excavations have been made. Besides the monasteries in the city of Limerick, the most important monastic ruins are those of Adare abbey, Askeaton abbey, Galbally friary, Kilfin monastery, Kilmallock and Monaster-Nenagh abbey. The Ardagh chalice, now in the Dublin National museum, came from the county and is one of the most perfect specimens of Irish jeweled metalwork.

A county council meets at Limerick, the county town, and there is a county manager. Limerick city is a borough with mayor and corporation and a city manager who is a separate official from the county manager. Newcastle West and Rathkeale are administered by town commissioners. For electoral purposes there are two constituencies of East and West Limerick, the former returning four members and the latter three members to *dáil éireann*. Except for Limerick (pop. [1961] 50,786), only four places within the county have more than 1,000 people: these are Newcastle West, Rathkeale, Kilmallock and Abbeyfeale.

Limerick, the biggest town on the west side of Ireland, is a distributing centre for an area far wider than the county. It has two cathedrals serving dioceses roughly coterminous with the county. None of the country towns and villages has become industrialized, except for a few local mills. The numerous villages are shopping centres and many have fairs. Though they are fairly prosperous, their populations do not increase.

Much of Limerick lies within the Golden vale which spreads into County Tipperary round Tipperary town and Cashel. It is famed for its rich pastures and is a main centre of dairying. Nine-tenths of the county is used for crops and pasture, and in many areas almost all the land is under grass and hay, for the main wealth lies in the dairy herds. Surplus stock is sold at fairs and near the city of Limerick there are good fattening pastures. Pig production is to some extent associated with dairying, as the animals are fed on the residue after the cream is separated. Bacon curing is an old-established industry in the city of Limerick. The village of Foynes on the Shannon was the terminus of a transatlantic seaplane service until it was superseded by the establishment of the Shannon airport in County Clare.

See P. Fitzgerald and J. J. McGregor, *The History, Topography and Antiquities of the County and City of Limerick*, 2 vol. (1826–27); Maurice Lenihan, *Limerick: its History and Antiquities* (1866). (T. W. Fr.; Hv. S.)

LIMERICK (LUIMNEACH), a county borough, port and the chief town of County Limerick, Republic of Ireland, occupying both banks and an island (King's Island) of the river Shannon, at the head of its estuary, 129 mi. W.S.W. of Dublin by rail. Pop. (1961) 50,786.

Limerick is said to have been the Regia of Ptolemy and the Rosse-de-Nailleagh of the Annals of Multifernan. There is a tradition that it was visited by St. Patrick in the 5th century, but it is first authentically known as a settlement of the Norse, who sacked

it in 812 and afterward made it the principal town of their kingdom of Limerick but were expelled from it toward the close of the 10th century by Brian Boru. From 1106 till its conquest by the English in 1174, it was the seat of the kings of Thomond or North Munster, and, although in 1177 the kingdom of Limerick was given by Henry II to Philip de Braose, the city was frequently in the possession of the Irish chieftains till 1195. Richard I granted it a charter in 1197.

By King John it was committed to the care of William de Burgh, who founded English Town, and for its defense erected a strong castle. The city was frequently besieged in the 13th and 14th centuries. In the 15th century its fortifications were extended to include Irish Town, and until their demolition in 1760 it was one of the strongest fortresses of the kingdom. In 1651 it was taken by Gen. Henry Ireton, and after an unsuccessful siege by William III its resistance was terminated in 1691 by the treaty of Limerick (see *IRELAND: History: The Jacobite War, 1689-91*). The dismantling of the town's fortifications began in 1760, but fragments of the old walls remain. In 1609 it received a charter constituting it a county of a city and also incorporating a society of merchants of the staple, with the same privileges as the merchants of the staple of Dublin and Waterford.

The prosperity of the city dates chiefly from the foundation of Newtown Pery in 1769 by Edmund Sexton Pery (d. 1806), speaker of the Irish house of commons. Under the Local Government act of 1898 Limerick became one of the six county boroughs having a separate county council. The city is divided into English Town (on King's Island), Irish Town and Newtown Pery, the first including the ancient nucleus of the city, and the last the principal modern streets. The main stream of the Shannon is crossed by Thomond bridge and Sarsfield or Wellesley bridge. The first is commanded by King John's castle, on King's Island, a Norman fortress fronting the river. At the west end of the bridge is preserved the Treaty stone, on which the treaty of Limerick was signed in 1691. The Protestant cathedral of St. Mary, also on King's Island, was originally built in 1142-80 and exhibits some Early English work. The modern Roman Catholic cathedral of St. John is in early pointed style. The churches of St. Munchin (to whom is attributed the foundation of the see in the 6th century) and St. John, Whitmore's castle and a Dominican priory are of interest.

Communication with the Atlantic ocean is open, while inland navigation is facilitated by a canal which avoids the rapids above the city. Quays extend on each side of the river, and vessels of 600 tons can moor alongside at spring tides. There is a graving dock and a wet dock. The principal imports are grain, timber, oil and coal. The exports consist mainly of fish and agricultural produce. The principal industrial establishments include flour mills

(Limerick supplying most of the west of Ireland with flour), factories for bacon curing and for condensed milk and creameries. Some brewing, distilling and tanning are carried on, and the manufacture of lace is maintained at the Convent of the Good Shepherd. The salmon fisheries of the Shannon, for which Limerick is the headquarters of a district, are the most valuable in Ireland. The city benefited greatly from the establishment of the Shannon hydroelectric power station close by (see *SHANNON*) and from the proximity of Shannon airport, about 20 mi. to the west.

LIMERICK. The origin of this popular type of nonsense verse is unknown. Langford Reed, the limerick's only historian and principal anthologist, suggested that the name derives from a song brought back from France by returning members of the Irish brigade in the 18th century, the chorus of which was "Will you come up to Limerick?" To this chorus impromptu verses were added, telling the adventures of persons from various Irish cities. Reed did not state the source of this tradition, for which there is no confirmation.

The first English verse in something like limerick form is the jingle "Hickory, Dickory, Dock," of which the earliest printed version dates from 1744. The French epigram, "On s'étonne ici que Caliste," quoted by James Boswell in his *Life of Johnson*, dates from 1716. Again the form is not identical, but this, and the existence of a French version of "Hickory, Dickory, Dock," offers some support to Reed's theory of a French origin.

The first collections of limericks in English date from about 1820. Edward Lear (q.v.), who composed those in his *Book of Nonsense* (1846) in the early 1830s to amuse the children of his friend the earl of Derby, claimed to have got the idea from a nursery rhyme beginning "There was an old man of Tobago." This is quoted by Eugene Wrayburn at the Veneerings' dinner table in chapter ii of Dickens' novel *Our Mutual Friend*, but Wrayburn remembers it only partially. He gives the rhymes "Tobago" and "dago," but forgets the almost certain second line ending, "sago." Instead he says "isinglass," and he gives no hint of the third and fourth lines.

Lear's limericks are, on the whole, less developed in form than his hypothetical model, since his fifth line usually repeats the rhyme word of the first or second, as in the case of the typical "Old Person of Rheims":

There was an Old Person of Rheims,
Who was troubled with horrible dreams;
So, to keep him awake,
They fed him on cake,
Which amused that Old Person of Rheims.

The last line of a Lear limerick is certainly its weakest member. However there are some in which he uses the full form with a new rhyme word for the fifth line, as, for example, in:

There was an Old Man who supposed
That the street door was partially closed;
But some very large rats
Ate his coats and his hats,
While that futile Old Gentleman dozed.

Here, however, Lear departed from the original "Tobago" form, which he more usually followed, of ending the first line with the name of a place or country.

Langford Reed quotes Bernard Shaw's opinion that "Edward Lear's *Book of Nonsense* is the only collection which any reputable publisher or printer could touch." Certainly the limericks of the Pre-Raphaelite circle were reputed both libelous and indelicate. Those of D. G. Rossetti's that survive are dull and careless. Other men of letters toward the end of the century were far more expert. W. S. Gilbert, for instance, in his sequence of limericks which Sir Arthur Sullivan set as the song in *The Sorcerer* (1877):

Oh, my name is John Wellington Wells,
I'm a dealer in magic and spells,
In blessings and curses,
And ever-filled purses,
In prophecies, witches and knells.

Gilbert also wrote one of the first offbeat limericks, which were to become almost as popular as the true sort, their charm lying in

BORD FAIRLE

KING JOHN'S CASTLE AND THOMOND BRIDGE WITH ST. MUNCHIN'S PROTESTANT CHURCH IN THE BACKGROUND, AS SEEN FROM CLANCY'S STRAND, LIMERICK, ON THE RIGHT BANK OF THE SHANNON

the unexpected jolt of failing to find the expected rhyme:

There was an old man of St. Bees,
Who was stung in the arm by a wasp,
When asked, "Does it hurt?"
He replied, "No, it doesn't,
I'm so glad it wasn't a hornet."

Rudyard Kipling, Arnold Bennett, E. V. Knox, Ronald Knox, Dean Inge and Pres. Woodrow Wilson contributed some noteworthy limericks to the Edwardian repertory, which was also enriched by a stream of "bluer" specimens, attributed, without proven basis, to members of the stock exchange. Many of these anonymous verses circulated in several versions of varying decency.

The limerick had, by the first decade of the 20th century, acquired widespread popularity; and in 1907-08 limerick contests were organized by journals and business houses either for the completion of the last line, or for original verses composed on a certain place name or to advertise a particular product. The sale of rhyming dictionaries is said to have boomed. The true limerick addict, however, transferred his attention to more complicated verses, of the type of the anonymous tongue twister:

A tutor who taught on the flute
Tried to teach two young tooters to toot.
Said the two to the tutor,
"Is it harder to toot, or
To tutor two tooters to toot?"

Others wrote limericks in French or Latin, and yet others exploited the anomalies of English orthography. An example of the first, written in unidiomatic French, betrays its English origins in every line:

Il était une jeune fille de Tours
Un peu vite, qui portait toujours
Un chapeau billy-coque,
Un manteau peau-de-phoque,
Et des p'tits pantalons de velours.

while that on the lady of Leicester betrays an insular pride in the illogical spelling of certain place names:

An obstinate lady of Leicester
Wouldn't marry her swain, though he preicester.
For his income, I fear,
Was a hundred a year
On which he could never have dreicester!

Others pithily summed up the intellectual quandaries of the day. Ronald Knox's comment on the nature of reality has almost outlived the original arguments which he satirized:

There once was a man who said, "God
Must think it exceedingly odd
If he finds that this tree
Still continues to be
When there's no one about in the quad."

(Reproduced by kind permission of Monsignor R. A. Knox's literary executor, Mr. Evelyn Waugh.)

And the argument about predestination which raged in Oxford early in the 20th century is immortalized in a limerick by Maurice E. Hare:

There once was a man who said, "Damn!
It is borne upon me that I am
An engine that moves
In predestinate grooves,
I'm not even a bus, I'm a tram."

Later in the 20th century the limerick lost caste, yielding its popularity to the more offhand cleriheo (*q.v.*) and to the various forms of quatrain used by the U.S. poet Ogden Nash. Its hold remains strong only on the bluer portion of its former empire. Competitions seldom call for the limerick, and very few new examples seem to gain currency.

The best limericks, according to E. V. Knox, "have the consecutive fluency of conversational prose, the metre being faultlessly dactylic throughout," and as the perfect example he quotes:

There was an old man of Khartoum
Who kept two tame sheep in his room:
"For," he said, "they remind me
Of one left behind me,
But I cannot remember of whom."

This piece is not dactylic. Most limericks are in fact roughly anapaestic. But it fulfills his further requirement that it shall "contain the largest amount of improbable incident or of subtle innuendo that can be crowded into the available space." By Knox's standards some of Edward Lear's best pieces would fail, since they make only one zany point. Some of the most memorable limericks syncopate the last line, and endless variations of internal rhyme and dissonance have been used to vary a verse form which would otherwise have grown monotonous. Little except the number of lines and the rhyme scheme is constant in the limerick, and even the latter is provocatively isolated in one of the most famous of offbeat limericks, which outdoes its Gilbertian model:

There was an old man of Dunoon
Who always ate soup with a fork.
For he said, "As I eat
Neither fish, fowl, nor flesh,
I should otherwise finish too quick."

See Langford Reed (ed.), *The Complete Limerick Book* (1925).
(Jo. M. C.)

LIMES, a Latin word, originally meaning "path," which came to mean especially a frontier of the Roman empire (sometimes, but not invariably, an artificial frontier as opposed to a natural one); traces of these frontiers survive in Europe, the middle east and north Africa. Earlier, the word *limes* was applied to any Roman military road. These were driven forward into subdued territory and linked up into a network, including watchtowers and forts, thus securing the country behind a further advance. Once a given line became regarded as a frontier rather than a lateral communication road, however, the towers and forts tended to be concentrated along it and the road between them was often replaced by a continuous barrier, though forts and *limites* ahead of or behind it were not necessarily abandoned.

The *limes* as a continuous barrier can best be seen in Britain (see below) and Germany. The Rhine and Danube rivers, adopted from A.D. 9 as the natural frontiers of the Roman empire, make an inconvenient re-entrant angle; Roman influence beyond them was consolidated under Vespasian (emperor 69-79) by the construction of roads and forts in the Black forest (the *agri decumates*; *q.v.*). The war of Domitian against the Chatti in 83 involved the construction of a chain of forts and towers along the Taunus ridge, soon linked via the Neckar river with a line running north of the Danube. Under Hadrian (117-138) and Antoninus Pius (138-161) the *limes* became a continuous nine-foot palisade running, in its final form, over 300 mi. from the Rhine opposite the Vinxbach river along the Taunus and south to the Main river, which it followed from Seligenstadt to Miltenberg, then in a straight line to Lorch and roughly east via Gunzenhausen to the Danube near Eining. The original appearance of the palisade and towers can be guessed from reliefs on the column of emperor Marcus Aurelius at Rome. The palisade was replaced under Caracalla (212-217) by a stone wall east of Lorch and supplemented by an earth wall (*vallum*) and ditch west of it. The Alamanni broke through the *limes* c. 260 and the Roman frontier was withdrawn to the Rhine and Danube once more.

The *limites* in Britain are Hadrian's Wall (*q.v.*) between the rivers Tyne and Solway and, farther north, the turf wall of Antoninus Pius (see **BRITAIN: Roman Britain**) between the rivers Forth and Clyde. In modern Rumania an earth wall with forts (perhaps built under Domitian) and a later stone wall running from near Cernavoda on the Danube to Constanța (ancient Tomis) on the Black sea are the most conspicuous signs of the *limes* in the Dobruja area, part of the lower Danube defenses. From 106 to c. 270 these were extended northward to include Dacia (*q.v.*); on the east, lines of forts have been traced from the Danube along the Olt river to the Red Tower pass and from Flaminda via Pitești and Cimpulung to Brașov, and on the west in the Mezeș mountains, especially near Moigrad (ancient Porolissum). The roads and fortifications along the Danube were, however, maintained during the occupation of Dacia.

In Asia Minor a continuous barrier was neither practicable nor necessary, as the Romans controlled the roads and river crossings. In Syria, however, an elaborate *limes* system was established, as

much to control the transhumant native population and the caravan routes as for defense against Parthian or Persian attacks. The chief road, known as *strata Diocletiana* after the emperor (284–305) who reorganized it, ran from Bostra (Busra) via Damascus to Palmyra (*q.v.*) and Sura (Suriya), then down the Euphrates and up the Chaboras (Khabur) river to join the eastern frontier cities of Nisibis (Nusaybin) and Singara (Sinjar). From Bostra another road led southward through Arabia to the Gulf of Aqaba. The eastern end was partly abandoned by Jovian (363), but the main line held until the Arab conquest in the 7th century.

In north Africa control of nomads was also necessary. The network system of roads, forts and watchtowers was adopted, but the defenses also included a continuous barrier, a ditch and either a stone or earth wall. In the 5th century, this was known as the *fossatum*, while the term *limes* was applied to the whole system. Here there is particularly good evidence—ancient irrigation- and field-systems—for the settlement of the *limes* area by *limitanei*, the frontier forces of the later empire, who cultivated land in the *limes* area on condition of manning the *limes*.

LIMESTONE, a rock containing at least 50% calcium carbonate, CaCO_3 , but generally not including such rocks that have been recrystallized and chemically altered by metamorphism (see MARBLE). Limestones are typically soluble in cold dilute acids and have a specific gravity of 2.6 to 2.8. They are soft, for calcite, the most abundant mineral constituent, has a hardness of only 3, and are white to cream-coloured unless stained yellow or brown by iron oxides or rendered bluish to black by included organic matter and iron disulfide. Limestones are typically well cemented and without large amounts of intergranular porosity, although chalk and calcareous sinter are incoherent and earthy.

Limestone is appreciably soluble in water enriched in organic acids and carbonic acid, such as ground water which has passed through soil. Terrain which is underlain by limestone in humid regions develops underground drainage and the characteristic karst topography, and abounds in caves and sinkholes (see CAVE). Limestones are noteworthy in that extensive solution and reprecipitation may take place in them after formation, sufficient in some cases to obscure fossils and other evidence of their manner of formation.

Formation and Composition.—The carbonate portion of limestones consists of mixtures in various proportions of land-derived detrital particles, or debris, of older limestone, fecal pellets of invertebrates, fossils and fragments of partly consolidated limestone torn loose by waves in the depositional environment. These materials are cemented by microcrystalline carbonate ooze and coarser-grained pore-filling calcite cement. With increasing numbers of dolomite (*q.v.*) crystals replacing the calcium carbonate of the rock, limestones grade into dolomitic (*i.e.*, rich in magnesium carbonate) limestones and dolomites. The noncarbonate minerals include detrital quartz and feldspar and resistant minerals such as zircon, garnet and tourmaline. Calcium phosphate and silica are contributed by the shells of some organisms. Well-formed crystals of albite and monoclinic potash feldspar, quartz, pyrite and other minerals which grew in the rock during or after its formation are said to be authigenic. The nodules and bands of chert (flint) which replace limestones can be shown in some cases to have resulted from concentration of silica originally present in organic spicules and tests.

Most limestones are partly or entirely of organic origin. The soft, whitish limestones known as coquinas are composed almost entirely of shells and shell fragments, and were formed in warm shallow water like that around the Bahamas today, where organisms grew abundantly and the waves were able to wash away finer-grained material. Some chalks are largely composed of foraminifera such as *Globigerina*. Another foraminiferal limestone, that made by the disc-shaped *Nummulites*, is famous as the

rock from which the pyramids of Egypt were built. Crinoidal limestones are found in older rocks such as the Carboniferous.

Reef limestones were formed by organisms that were able to erect rigid wave-resistant structures in relatively shallow water near upwelling currents rich in nutrients. Corals and calcareous algae are the principal frame builders today in places such as the Pacific atolls and the Great Barrier reef of Australia, but other organisms played this role in the past. Reef limestones are very pure carbonate rocks, and are often dolomitized.

The oolites in oolitic limestones are composed of CaCO_3 chemically deposited about nuclei of various kinds. The purer oolitic limestones contain very little fine-grained material and were formed in agitated water like that overlying the underwater oolite dunes near the edge of the Bahaman platform.

The origin of fine-grained limestones is frequently in doubt because of recrystallization of original features. Some probably were formed from the minute remains of primitive unicellular organisms (coccolithophores and rhabdoliths), others from tiny aragonite (*q.v.*) needles like those resulting from chemical precipitation and from the disarticulation of algal remains in the drewite muds of the Bahamas. Fine grained limestones containing appreciable amounts of clay minerals, pyrite and organic matter were formed below the level of wave action where tiny detrital particles could settle out, in a stagnant, oxygen-poor environment suitable for the preservation of organic matter and the formation of pyrite.

Limestones and dolomites associated with beds of anhydrite and salt, as in the rocks of Permian Age west of the great Capitan reef in west Texas and New Mexico, contain very few fossils and are believed to be chemical precipitates from saline waters concentrated by evaporation. The solubility of these carbonates is such that they should precipitate before anhydrite and salt. This sequence of precipitation is observed today in a long narrow inlet on the arid Peruvian coast.

Limestones formed from accumulations of carbonate rock particles carried by streams are found in the Arbuckle mountains of Oklahoma and in the region north of the Alps. Such rocks are uncommon and formed only in regions of high relief and abundant limestone outcrops, for limestone particles are quickly reduced in streams by abrasion and solution. Relatively common along tropical coasts, however, are limestones formed by the cementation of calcareous beach deposits and dunes.

Lakes in regions such as the north central part of the United States, where ground waters contain large amounts of calcium carbonate dissolved from glacial drift, contain fine-grained carbonate-rich deposits precipitated in large part by the activity of fresh-water algae. The deposits in Lake Zurich are made up of seasonal layers or varves which are alternately rich in carbonates and in organic matter. The dolomitic lake deposits of Eocene Age in Wyoming and Utah are also varved but the varied and unusual suite of authigenic minerals here indicates that the lake waters became highly concentrated.

Occurrences of limestone are discussed in articles on the various geologic systems and epochs, as CRETACEOUS SYSTEM; EOCENE AND PALEOCENE, etc., and on states and countries, as INDIANA; JAPAN. (See also GEOLOGY; OCEAN AND OCEANOGRAPHY: *Marine Sediments*; SEDIMENTARY ROCKS.)

Uses.—Limestone has a large variety of economic uses. High purity calcium carbonate rock is used in the production of sodium carbonate from sodium chloride (salt) by the Solvay process, the manufacture of aluminum oxide (alumina) by the Bayer process, production of synthetic phenol, calcium nitrate, dyestuffs and intermediates, and the refining of beet sugar by the carbonation process.

It is a food supplement for livestock and poultry and is used in whitening (see also CHALK) and as a reactant in the refining of salt brines and the manufacture of glass. The calcination of limestone at temperatures high enough to dissociate calcium carbonate yields both carbon dioxide and lime for commercial use. The latter is used in the construction industries and in manufacturing chemicals including calcium carbide, which is produced by fusing lime with coke in the electric-arc furnace.

Limestones containing impurities of the proper kind and amount are desired for some purposes, although other materials can be mixed with high purity limestone to achieve the same result. The manufacture of portland cement requires one part of shale or clay to three or four parts of limestone. Natural cement is made from rock containing 10% to 22% silica and 4% to 16% aluminum oxide and iron oxide. Rock wool manufacture requires 45% to 65% calcium carbonate (or magnesium carbonate), with the remainder of the rock principally silica.

Limestones may be phosphatic because of original concentrations of phosphatic shells or pellets. On some Pacific islands they become phosphatized from the replacement of carbonate by phosphates removed by ground water from guano. Such rock-phosphate is used for artificial fertilizers. Limestones, because of their susceptibility to attack by acid hydrothermal solutions, are also hosts for deposits of many valuable metals. Like other sedimentary rocks, they may contain accumulations of petroleum and natural gas.

Rocks high in dolomite are used for the manufacture of Epsom salts, of basic magnesium carbonate, which is mixed with asbestos for an insulating material, and of high-magnesium lime which is used in the building industry and in the production of certain chemicals such as magnesia. Dead-burned dolomite is used for patching and repair of basic open-hearth furnaces and for electric furnace bottoms.

There are many applications for which either limestone or dolomite may be used. These include monuments, exterior and interior facings and floors in buildings, flagstone for walks, and chips for roofing, stucco, etc. Crushed rock is used for railroad ballast, riprap fill around the base of dams, piers, etc., filter beds in sewage treatment and surfacing for airports, playground, tennis courts, etc. It is employed extensively in road construction, either alone or mixed with cement or bitumen, and as aggregate in making concrete for buildings and other structures. Agstone (crushed limestone for agricultural and other uses) is employed to regulate soil acidity, to improve soil structure, and to furnish nutrients. Used as fluxes in blast furnaces producing pig iron, during the manufacture of steel in basic open-hearths, and in nonferrous metal smelters, limestone and dolomite combine with impurities to form a slag which can be removed. More finely ground material is added as a filler and conditioner in fertilizers and is employed in the manufacture of paper by various processes.

The specifications for carbonate rock vary greatly with the particular application. Colour is particularly important for many uses of whitening substitutes. Poultry grit should contain less than 0.1% fluorine. A low iron oxide content is particularly important in glassmaking, and building stone used on exterior surfaces should not contain pyrite or marcasite which would yield iron oxide stains on weathering. The total carbonate content is of cardinal importance for agstone. Resistance to repeated freezing and thawing is important for flagstone, for concrete aggregate, and for crushed rock in riprap and railroad ballast. Resistance to abrasion is a required quality of limestone for floors and for road surfaces. Limestones are preferred to dolomite for use in the neutralization of acidic sewage and industrial wastes because of higher reaction rate.

See QUARRYING; STONE; see also references under "Limestone" in the Index.

(D. L. G.)

LIMICOLAE, in former classifications an order or suborder of shore or wading birds, now known as the suborder Charadrii, including jaçanas, snipes, oyster catchers, lapwings, plovers, woodcocks, sandpipers, stilts, avocets, phalaropes, sheathbills (*qq.v.*), and pratincoles.

LIMINA APOSTOLORUM (literally, "The Thresholds of the Apostles"), an ecclesiastical term used to denote Rome and especially the church of St. Peter and St. Paul. A *Visitatio Liminum* might be undertaken *ex voto* (in accordance with a vow) or *ex lege* (in accordance with a law). In 743 a Roman synod decreed that all bishops subject to the metropolitan see of Rome should meet personally every year in that city to give an account of the state of their dioceses. Gregory VII and Sixtus V greatly enlarged the number of bishops subject to this law and Benedict

XIV in 1740 extended the summons to all abbots, provosts and others who held territorial jurisdiction. Under the regulation of Pius X established in 1909, the *Visitatio ad Limina Apostolorum* must be made, either personally or by representative, by all ordinaries and vicars apostolic who have jurisdiction; the periods are five years for those whose dioceses are in Europe and ten for those outside Europe. During the middle ages *ex voto* pilgrimages *ad Limina Apostolorum* were popular among laymen.

LIMING is the application of lime (calcium) materials to crop-land soils to improve productivity. The principal effects are: (1) to supply needed calcium and (2) to reduce soil acidity. This practice was known long before the Christian era and has been used since the beginnings of agricultural history (see *LIME; History*). It was not, however, until the early years of the 20th century that the underlying chemical principles began to emerge. By mid-20th century, the liming of noncalcareous soils in the humid regions of the world had become a most important land-use practice.

Chemically, liming materials are chiefly carbonates of calcium. They are found abundantly in nature as limestone, dolomite, chalk, marl (*qq.v.*) and shell, as well as in other forms. The soft forms, as chalk, can be prepared readily for applying and mixing with soils. The stone forms are of little use until reduced to suitable particle sizes. At one time this was done by burning and slaking. The development of rock crushing, screening and applying equipment in the first half of the 20th century quickly expanded the use of liming materials. With these developments, the amount applied to U.S. soils, to take one example, reached 25,000,000 tons annually.

Both crops and soils are involved in the need for and usefulness of liming materials. Crops require soil-derived calcium in various amounts and vary in their ability to obtain the supplies they need from different soils. For instance, buckwheat, a high-calcium requiring crop, can obtain its supplies from soils of low-supplying powers, while sweet clover, with a moderate requirement, does best on soils of high-supplying powers. Some reasons for such behaviour are: differences in feeding capacities; in ratio balances between basic and acidic soil components; and symbiotic effects which bring atmospheric nitrogen into the plant without accompanying basic components. Soils vary in their supply of calcium and in ability to release it, largely according to the variable amounts of clay-mineral complexes developed in the soil by soil-forming processes. These clays are characterized by various capacities for holding and exchanging basic chemical substances in which calcium and hydrogen are dominant.

In productive soils a large proportion of calcium is released to crops and drainage waters. Liming materials, if present, provide replacements; if not present, hydrogen is substituted and acidity begins to develop. As the acidity intensifies soils become less favourable for crop production: nutrient availabilities decline, soil micro-organisms are handicapped in their activities, substances toxic to plants may develop and physical conditions appear that lead to tillage, drainage and erosion difficulties. Well-planned liming practices will do much to correct these difficulties and to prevent their recurrence.

Liming practices are based chiefly on the principle of correcting acidity by supplying sufficient calcium to satisfy the base exchange requirements of soils for high productivity. Soil tests for acidity (pH) provide guiding information. Where low-cost limestones are abundant, a product with particle sizes ranging downward from an eighth of an inch to dust may be applied in larger amounts for immediate and long-time efficiency. Subsequent applications may not be needed for periods ranging upward from 4 years to as much as 12 or more years. Used in this manner, liming practices will do much to keep soils physically fit, chemically balanced and biologically active for continuing high productivity. See also FERTILIZERS AND MANURES; SOIL.

(F. C. BR.)

LIMIT, a concept fundamental in mathematical analysis, occurs in so many contexts that its general definition can only be given in the setting of general topology. Here will be given a sketch of its origin and principal occurrences. Among the an-

cients the method of exhaustion (so-named in modern times) was the precursor of the theory of limits; it was employed by Euclid and Archimedes in proofs of theorems concerning figures with curved boundaries. A circle, for example, may be approximated by a sequence of inscribed regular polygons (fig. 1), beginning with the square ABCD and the octagon AEBFCGDH and so on, each figure having twice as many vertices as the preceding. If each polygon is regarded as having removed its area from that of the circle, it seems clear that the latter is progressively exhausted, in the sense that the remaining area becomes smaller than any previously assigned amount, however small. If p_1 is the perimeter of ABCD, then $\left(\frac{p_1}{2}\right)a_1$ is the area of ABCD;

FIG. 1.—METHOD OF EXHAUSTION: POLYGONS APPROXIMATING THE CIRCLE

if p_2 is the perimeter of the octagon, then $\left(\frac{p_2}{2}\right)a_2$ is its area; and in general, $\left(\frac{p_n}{2}\right)a_n$ is the area of the n th approximating polygon. In modern language one would say that a_n becomes arbitrarily close to r , the radius of the circle, and p_n becomes arbitrarily close to $2\pi r$, the perimeter of the circle, as n increases. Thus $\left(\frac{p_n}{2}\right)a_n$ approaches $\left(\frac{2\pi r}{2}\right)r$ or πr^2 , which must therefore be the area of the limiting configuration, the circle.

This sort of argument was characteristic of the 18th century; actually, the ancients argued more closely: to prove the area of the circle could not be less than πr^2 they would imagine by way of contradiction that it was, say, πs^2 , with s less than r . Then an approximating polygon could be shown to exist whose area exceeded this amount. The part being less than the whole (for the polygon lay within the circle), this was impossible. That the area could not be greater than πr^2 could then be proved using circumscribed polygons, which exhausted the exterior of the circle. In the argument sketched here, there is not the slightest appeal made to notions of the infinite. The construction of polygons need not be pushed "to the limit"; some one finite polygon can be shown to produce the desired contradiction (see SCIENCE, HISTORY OF: *Alexandrian Science: First Period, 300–30 B.C.*).

Something, if not most, of the finite flavour of such rigorous argument was lost when, in the 17th century, the notion of limit appeared in the work of Newton, Leibniz and their successors in the development of the calculus. It seemed convenient, for example, sometimes to regard a curve (such as a circle) as a polygon of an infinite number of sides, each of infinitesimal length. Arguments based on such apparently nonsensical notions yielded results of such richness and scope that the ideas of the "infinitesimal calculus" survived the most devastating (and just) philosophical attacks. Yet errors and paradoxes occurred which were the work of a later era to resolve.

For example (fig. 2) the broken line ACB has twice the length of AB. So does ADEFB. So does AGHIEJCLB. If this process is continued, the area between the broken lines and AB diminishes to zero, and AB is clearly the limiting configuration. It might be argued that AB should therefore have twice its own length, because all the approximations do. This paradox is the result of the mistaken idea that the limiting configuration must

FIG. 2.—LIMIT PARADOX: THE POLYGONS APPROXIMATING STRAIGHT LINE AB ARE ALL TOO LONG

have properties which are the limiting cases of the corresponding properties of the approximating configurations. By such reasoning, however, one would have also to claim that AB had an infinite number of corners, each a 60° angle.

Beginning with the work of Augustin Cauchy on the convergence of infinite series the 19th century carried to completion the work of arithmetizing analysis. The notion of limit, previously quasi-geometrical, was put into numerical language and divested of all trace of the language of "ultimate behaviour."

Arithmetical Theory of Limits.—If $a_1, a_2, a_3, \dots, a_n, \dots$ is a number sequence, we say it has the limit L if the following statement is true: for every positive number ϵ , however small, there corresponds an index p such that if $n > p$ (n greater than p), then $a_n - L$ is less than ϵ in absolute value. Thus, for example, if $a_n = \frac{n}{n+1}$, i.e., if the sequence is $\frac{1}{2}, \frac{2}{3}, \frac{3}{4}, \dots$, the limit L is

clearly 1 because $a_n - L = \left(\frac{n}{n+1}\right) - 1 = \left(\frac{-1}{n+1}\right)$, whose absolute value is surely as small as any ϵ that might be named, once n is chosen answeringly large. In symbols, one writes

$$\lim_{n \rightarrow \infty} \left(\frac{n}{n+1}\right) = 1$$

Other sequences do not have so obvious a limit; a famous example is where $a_n = \left(1 + \frac{1}{n}\right)^n$. Here the limit is conventionally named e , and is approximately 2.71828. The proof, in this case as in many others, that a limit does exist makes use of the criterion of Cauchy: a sequence a_n has a limit if and only if to each positive ϵ there corresponds an index p such that $a_n - a_m$ is less than ϵ in absolute value whenever m and n both exceed p . Georg Cantor (about 1880) made this criterion a part of the definition of real number. If f is a real function, that is, if for each real number x there corresponds a real value $f(x)$, we say

$$\lim_{x \rightarrow a} f(x) = L$$

if the following statement holds: for every positive number ϵ , there is an interval I surrounding a (say all real numbers between $a - \epsilon$ and $a + \epsilon$) such that if x is in I , but x is not a itself, then $f(x) - L$ has absolute value less than ϵ . This definition gives precision to the intuitive notion " $f(x)$ is near L when x is near a " and makes possible the rigorous proof of the theorems connecting the limit-taking operation with the more usual arithmetic procedures. These theorems are at the root of the utility of the calculus.

Generalizations.—The statements " $f(x)$ is near L when x is near a ," and " a_n is near L when n is far out," whose precise definitions are given above, continue to have meaning even when the quantities involved are not real numbers or integers but instead are members of more general structures in which appropriate notions of nearness and far-outness have been defined. Nearness takes on meaning in all topological spaces, of which the real numbers, the complex numbers, and most geometric configurations are examples; and far-outness takes on a useful meaning in many ordered sets, of which the integers form an example.

LIMITATION, STATUTES OF, the name given to legislative acts restricting the times within which legal proceedings may be brought. Typically these statutes limit the time within which an action may be commenced to a fixed period after the occurrence of the events which gave rise to the cause of action, the length of the period varying with the nature of the action. These statutes, found in all systems of jurisprudence, are designed primarily to attain a degree of stability in the ordering of human affairs. It is commonly said that they are statutes of repose, enacted to protect

against stale claims after evidence has been lost, memories have faded or witnesses have disappeared.

In English-speaking jurisdictions, civil actions commonly are limited by general statutes which classify the actions into broad groups, such as those for the recovery of real property, actions on written contracts, actions on oral contracts and actions arising from torts. Although the periods prescribed are arbitrary, the classification bears a rough relation to the times for which reliable evidence of the respective transactions may be expected to endure. The bringing of actions for the recovery of real property and of actions on contracts under seal commonly is limited to periods of from 10 to 20 years after the cause of action arose. Actions on oral or simple written contracts usually are limited to periods of from three to six years, and those for personal injury to three years or less. There is considerable variation in the periods prescribed in different jurisdictions. Supplementing these general statutes of limitation are a large number of special acts which limit the times within which particular actions, or actions by or against particular parties, may be brought. Thus, in North Carolina and Tennessee an action for slander must be commenced within six months after the cause arose; in New York, the state may bring an action to recover land at any time within 20 years. In addition to actions for slander, actions for claiming forfeitures or penalties and those against certain public officials frequently are restricted by short periods of limitation. Proceedings involving the administration of the estates of decedents also are subject to short limitation periods, normally measured from the appointment of the executor or administrator. Special statutes, where applicable, replace the periods prescribed by the general limitation acts. In Great Britain virtually all civil limitation enactments are gathered in the Limitation act of 1939 (2 & 3 Geo. VI, c. 21) as amended by the Law Reform (Limitation of Actions) act of 1954 (2 & 3 Eliz. II, c. 36). Under these acts most limitations are standardized at either 3, 6 or 12 years.

General statutes of limitation uniformly include provisions allowing persons who are under a legal disability at the time a cause of actions accrues to bring the action within some fixed period after the disability has been removed. Infancy, imprisonment and insanity commonly are included in the disabilities so treated. A disability arising after the accrual of a cause of action will not suspend the running of the period of the statute; it must have existed at the time the cause of action arose. Fraud on the part of the defendant which prevents the plaintiff from discovering the existence of a cause of action prevents the running of the statute until the facts reasonably might have been discovered. Similarly, the period of the statute does not run while the defendant is outside the jurisdiction and thus beyond the reach of its courts, whether the defendant's absence exists at the time the cause of action accrues or occurs thereafter. The part payment of a debt, or other acknowledgment of it, generally is held to start the period of the statute running anew; but statutes in Great Britain and in about half of the states of the U.S., derived from Lord Tenterden's act (9 Geo. IV, c. 14), require a mere acknowledgment of a debt to be in writing and signed by the party to be charged before it will have that effect.

In civil actions, statutes of limitation have been held not to be applicable to a government suing in its own courts, an exception based on the theory of sovereignty. However, in many instances, legislatures have waived this governmental immunity by express statutory enactments.

General statutes limiting the times within which prosecutions for crimes must be begun are common in the Continental countries and in the United States. In the United States the periods normally are shorter than in Europe and the limitations are restricted to misdemeanours and, sometimes, minor felonies. As in the case of limitations on civil actions, the period prescribed in a criminal statute of limitation does not run in the case of a defendant who has fled or concealed himself in order to avoid prosecution. In England there is no general statute of limitation applicable to criminal actions, although statutes creating crimes frequently have included a time limit for the prosecution of the particular crime.

Statutes of limitation appeared early in Roman law and these are the basis of the limitations found in the Continental codes. In England a fixed period of limitation on actions to recover land was first established in 1540 (32 Hen. VIII, c. 2). The Limitation act of 1623 (21 Jac. I, c. 16) established limitations for personal actions, as well as for those for the recovery of real property. Later general statutes of limitation, English and U.S., have been modeled rather closely on this act.

LIMOGES, a city of south central France, capital of the old province of Limousin, chief town of the *département* of Haute-Vienne and seat of a bishop, is situated on the Vienne river 375 km. (233 mi.) S.S.W. of Paris by road. Pop. (1962) 113,378. Lying in an amphitheatre of hills which face south, it is about halfway between the Massif Central and the Atlantic. Boulevards surround the site of the old town, which is crossed by the modern Rue Jean Jaurès. There is the cathedral of St. Étienne, a 13th-century building with a fine choir and choir screen, and a noteworthy apse and portal. The church of St. Pierre dates from the 12th and 13th centuries; that of St. Michel des Lions (14th and 15th centuries) has a tower 198 ft. high, with a spire surmounted by an enormous bronze ball. It contains the relics of St. Martial, patron of the town. Both churches contain 15th- and 16th-century stained glass. Also of interest are the former Jesuit college (17th and 18th centuries), the presidential court (18th century) and the former bishops' palace (18th century) with fine gardens and terraces overlooking the valley of the Vienne. Of the bridges over the river, those of St. Martial (4th-century foundations) and St. Étienne (13th century) are outstanding. Among modern buildings, the most important are the town hall (1883), the law courts, the railroad station (1929) and the municipal sports ground (1946-59). Limoges is well supplied with educational establishments. There are a municipal library and two museums—the Adrien Dubouché National Museum of Ceramics, the richest in France after Sèvres, and the municipal museum in the former bishops' palace, which has a collection of old enamel.

Limoges is on the main railway from Paris to Toulouse; other lines run to Bordeaux, Angoulême, Montluçon and Clermont-Ferrand. The chief industry is the manufacture of porcelain, which goes back to the second half of the 18th century. Enamelware, shoes, gloves, paper and furniture are also manufactured, and precision engineering, weaving and printing are carried on. The discovery of uranium in Limousin opened new vistas for the industrial activity of the region. Limoges is the centre of the stock-farming district and thus is important in the meat trade.

The town owes its beginnings to a ford across the Vienne, hence its Celtic name of Ritu. It was the capital of a Gallic tribe, the Lemovices. It sent a large troop under Sedulix to help Vercingetorix defend Alesia. Under Roman rule the town added Augustus' name to its own and was known as Augustoritum, but in the 4th century it was called Lemovice. It was an important road centre and at that time possessed palaces and thermal baths as well as having its own senate and currency. Christianity was brought there by St. Martial early in the 4th century. The town was destroyed by barbarian invaders in the 5th century, and the survivors built a town on the rock where the cathedral was later erected. This was known as the "city." In the 9th century another town was constructed about 2,000 ft. away, the "castle town"; it enclosed the castle of the counts and the abbey of St. Martial (demolished in 1794) in the old crypt of which was found St. Martial's tomb. The two towns, one under the bishops' authority, the other under the abbots', then the viscounts' and finally the consuls', remained separate until 1792. In the Hundred Years' War the castle town came under the English while the city remained loyal. In 1370 the city was besieged, stormed and sacked by the Black Prince. In the middle ages Limoges was famous for the work of its enamelers and goldsmiths. It was also an important centre for manuscripts made by the monks of the abbey of St. Martial. Plague, famine and the wars of religion devastated the

town until the 16th century, but under great administrators, especially the marquis de Tourny and A. R. J. Turgot in the 18th century, the town recovered its former prosperity.

Every seven years Limoges celebrates the feast of the Ostensions when the relics of St. Martial are exposed for seven weeks and attract numerous visitors. These ceremonies go back to the 10th century and commemorate the miracle by which the saint is said to have halted an outbreak of the plague.

See also references under "Limoges" in the Index. (R. DA.)

LIMÓN, principal Caribbean port of the republic of Costa Rica. Pop. (1960 est.) 15,806. Located in the vicinity of the land seen by Columbus in 1503, Limón was used alternately with other small ports by Spanish colonial merchants as well as smugglers and was the occasional target of pirate and Mosquito Indian attacks. It began to grow in importance after the end of the William Walker filibustering era (see WALKER, WILLIAM) and about 1867 the port was opened to foreign commerce. Under the leadership of Minor Keith, an American, a railroad through very difficult terrain finally joined Limón and San José in 1890. Construction cost 4,000 lives and about \$8,000,000. Much of the construction was done by West Indian Negroes who, until the 1940s, were prohibited by law from migrating to other Costa Rican provinces. The banana industry was developed along the tracks to provide a cash cargo, and by 1900 the United Fruit company had taken the lead in this business.

The chief business of Limón is exporting and importing and it yearly handles more freight than any other port in Costa Rica. Limón is the capital of Limón province, area 3,591 sq.mi., pop. (1960 est.) 59,240. The province is an area of heavy rainfall (about 100 in. annually) that produces sugar cane and two corn crops a year. The region suffered from Panama disease in the 1930s, banana production fell drastically and about 100,000 ac. of banana land were abandoned as the companies moved to the Pacific coast of Costa Rica. (T. L. K.)

LIMONITE, a natural hydrated ferric oxide, is one of the major iron-bearing minerals. The name is from the Greek word for meadow, in allusion to its occurrence as bog ore in meadows and marshes. Limonite was originally considered to be one of a series of hydrated ferric oxides, some with specific names, including turgite, limonite, xanthosiderite and limnrite. Investigation showed, however, that there is only one hydrated form, $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$. This compound is dimorphous, and occurs in two crystalline forms which differ in the nature of the hydrogen-oxygen bonds, and whose formulas may be written as follows: goethite, HFeO_2 and lepidocrocite $\text{FeO}(\text{OH})$. It was then assumed that limonite was this monohydrate in an amorphous condition, but X-ray studies clearly established the fact that most of the so-called limonite, especially the type with a radial fibrous structure, is distinctly crystalline, and is actually goethite.

The name limonite should properly be restricted to impure hydrated iron oxide, with variable water content, and colloidal or amorphous in character. It is sometimes pitchlike or has a vitreous lustre, with a black colour, occurring in stalactitic or botryoidal forms; or more commonly as earthy or porous masses, brown to yellow in colour (yellow ochre). The streak is yellow-brown. The hardness may be as high as 5.5, but usually is apparently less. It is commonly mixed with clay, sand and manganese oxide. It is formed as an alteration product of other iron minerals, such as the hydration of hematite or the oxidation and hydration of siderite and pyrite. See also GOETHITE; IRON AND STEEL INDUSTRY; Iron Ore. (L. S. RL.)

LIMOSIN (LIMOUSIN), **LÉONARD** (c. 1505-c. 1577), French painter best known for his fine portraits in enamel, the most famous of a family of seven enamel painters of Limoges, was the son of an innkeeper in that city. He was influenced at the beginning of his career by the German school; indeed, his earliest authenticated work, signed "L. L." and dated 1532, is a series of 18 plaques of the "Passion of the Lord," after Albrecht Dürer. But this influence was counterbalanced by that of the Italian masters of the school of Fontainebleau, Primaticcio, Rosso, Giulio Romano and Solario, from whom he acquired his taste for arabesque ornament and mythological subjects. Nevertheless, the

French tradition was sufficiently ingrained to save him from becoming an imitator. In 1530 he entered the service of Francis I as painter and *varlet de chambre*, a position which he retained under Henry II. For both these monarchs he executed many portraits in enamel—among them plaques depicting Diane de Poitiers in various characters—plates, vases, ewers and cups, besides decorative works for the royal palaces, for, though he is best known as an enameler distinguished for rich colour, and for graceful designs in grisaille on black or bright-blue backgrounds, he also enjoyed a great reputation as an oil painter. His last signed works bear the date 1574, but the date of his death is uncertain, though it could not have been later than the beginning of 1577. He executed nearly 2,000 enamels. He is best represented at the Louvre, which has his two famous votive tablets for the Sainte Chapelle, each consisting of 23 plaques, signed "L.L." and dated 1553; and many portraits. See also ENAMEL: *Origin and European Development*.

LIMOUSIN, a geographical region and, in a more limited sense, a historic province of France. For the geographer, Limousin is the western part of the Massif Central; i.e., the wide zone of Archean and primary rocks that spreads from the upper valleys of the Cher and the Dordogne, over the three *départements* of Haute-Vienne, Corrèze and Creuse (qq.v.) and the *arrondissements* of Confolens in Charente and Nontron in Dordogne. Little affected by the Tertiary earth movements, it consists mostly of peneplains or rolling plateaus and falls slowly from 3,018 ft. in the Montagne Limousine to 1,000 ft. in the west; yet it is a hilly country with deep river valleys. The rough climate and the low fertility of the acid soils gave it a reputation for poverty.

Limousin, as well as its chief town, Limoges (q.v.), takes its name from that of the Lemovices, whose territory in prehistoric Gaul was probably at least as large as the geographical region. Subdued by the Romans in 49 B.C., the tribal community or *civitas* of the Lemovices was included in the province of Aquitaine in 27 B.C. Under Frankish rule from A.D. 507, the pagus Lemovicinus, or Limousin district, was disputed by rival Merovingian kings; and from 760 to 768 the Carolingian king Pepin and Waifer of Aquitaine fought over it. With the growth of feudalism, however, the country lost its administrative unity. By the middle of the 11th century the viscounts of Limoges (recorded from 876) had scarcely more authority than the viscounts of Comborn, of Turenne and of Ventadour; border zones of the old pagus were annexed by the counts of Poitiers, of Auvergne and of Angoulême; and as early as 944 the northern areas of the pagus were erected into the separate countship of Marche (q.v.).

The feudal disruption of Limousin in the middle ages was offset by three factors. First, there was the continuing prestige of the bishops of Limoges, whose diocese was undiminished and who played a role both as protectors of the people and as mediators in dynastic conflicts. Second, Limousin preserved its cultural tradition, thanks not only to its great abbeys, such as that of St. Martial at Limoges, but also to its possession of an individual dialect, which was taken as a model by the troubadours. Third, the local feudatories themselves, however envious they were of each other, were drawn mainly from indigenous stock and closely intermarried. A concrete manifestation of the regional culture is provided by the enamels of Limoges, renowned from the 12th century (see ENAMEL).

The marriage of Eleanor of Aquitaine to the future Henry II of England (1152) brought suzerainty over Limousin to the Plantagenet dynasty. In the ensuing Anglo-French wars the local viscounts transferred their allegiance according to expediency. Philip II Augustus and Louis VIII recovered Limousin for France; but by the treaty of Paris (1259) Louis IX conceded to Henry III of England such rights as Henry II had enjoyed over fiefs and domains within the boundaries of the diocese of Limoges—an arrangement fraught with controversy because the lands in question were not enumerated and because the local lords could appeal over the English king's head to his French suzerain. Consequently the French retained their hold on Limousin. With the Hundred Years' War the English began incursions; and the whole country was ceded to them in full sovereignty under the treaty of Brétigny.

(1360). The French reconquest, started in 1370, was complete by 1374; later English counterattacks, baronial rebellions and devastation by mercenary companies had only a temporary effect.

In the last centuries of the *ancien régime* the intendant of Limoges was responsible for a *généralité* established from 1586 to comprise Angoumois and Basse Marche, as well as the province or military *gouvernement* of Limousin, which was coextensive with the territory of the four feudal viscounties. The viscounty of Limoges, having passed by marriage through the houses of Comborn, of Brittany and of Blois to that of Albret, was formally annexed to the French crown by Henry IV in 1607, but Turenne survived as a fief till the house of La Tour d'Auvergne sold it to the French crown in 1738. In the 18th century the intendants worked to develop the economy and produced a fine system of roads; and the manufacture of porcelain was begun at Limoges and at St. Yrieix-la-Perche. Yet the country was poor and backward at the time of the French Revolution. Dissolved into *départements* in 1790, the country as a whole did not begin to prosper till the construction of railways (from the 1850s onward). Then the import of fertilizers led to a great expansion of agriculture and stock raising, while industrial products (porcelain and footwear) found markets throughout France. During World War II, there was widespread guerrilla warfare in the region.

LIMPKIN (*Aramus guarauna*), a large raillike bird of the Americas, constituting the family Aramidæ, closely related to the crane (*q.v.*). It is 28 in. long and brown with white spots from head to wing bases. Called also courlan or crying bird from its loud, prolonged, wailing cry, and limpink from its peculiar halting gait as it hunts along the ground, it ranges the lowlands from central Argentina north to the southeastern U.S., Puerto Rico and Hispaniola. One race (*A. g. pictus*) is resident in the Florida peninsula and southern Georgia (Okefenokee swamp). It is found along borders of wooded streams, bayous, sloughs or in open marshes, sometimes uplands, where it runs raillike through brush with long strides or perches on small trees. The limpkin flies like a crane, with short concave wings slowly flapping, neck extended and legs dangling. It feeds on mollusks, crustaceans, aquatic insects, frogs and worms. In the Everglades it feeds chiefly on large, greenish fresh-water snails (*Ampullaria*). These, carried to its nest or favourite feeding perch and held firmly in one foot, are struck several powerful blows with the four-inch bill; the bill is then forced into the spiral opening of the shell to pull out the animal. The bulky nest of leaves, twigs and Spanish moss is found among grasses or shrubs, or in a low tree over or near water; the eggs, four to six, rarely eight, are buff splashed with brown and drab. (G. F. Ss.; X.)

LIMPOPO (CROCODILE or KROKODIL), a river of southeast Africa and, next to the Zambezi, the longest river of Africa entering the Indian ocean. Parts of it are also known by the local names of Oori and Bembe. The name Limpopo is thought to be connected with an African word, *uku popozi* ("to rush"), but this connection is conjectural. The river, whose length is about 1,100 mi., rises on the northern slopes of the Witwatersrand in the southern Transvaal, where its upper course is known as the Krokodil, a name sometimes applied to the whole river. It flows northward transversely to the Magalies mountains, through which it cuts at the Hartbeestpoort gap, the site of a dam. To the north of the Magaliesberg the river flows across the Bushveld basin (see SOUTH AFRICA, REPUBLIC OF: *Physical Geography*). Passing into the open granite country, the Crocodile is joined by the Marico river, after this confluence being known as the Limpopo. About 33 mi. farther downstream it is joined on its right bank by the Notwani, a headwater from the Kalahari.

Farther north the river enters country made rugged by outcrops of Waterberg sandstone and other hard formations where it receives two large right-bank tributaries, the Palala and the Magalakwin, and on the left bank the Maklausi. Below the Maklausi confluence the river receives the Shashi and turns eastward in the direction of the faulting of the Limpopo trough, which extends to the Mozambique boundary. Near Liebig's drift, a mile or two above the Beitbridge, which connects Southern Rhodesia

with the Republic of South Africa, the river forms the Tolo Azimé cataract, in which it falls about 40 ft. over a dolerite dike intruded into the Primitive rocks of this part of the basin. From this point to a little above the Pafuri confluence, nearly 100 mi. downstream, is the fall zone, in which the river passes from the plateau surface to the Mozambique plain. The three largest cataracts, according to W. Ramke, the South African geographer, are at Malala drift (about 30° 35' E.), Molukwe (about 30° 40' E.) and, a little lower, at Quiquequi, the total fall in the zone being about 800 ft., most of it concentrated in 27 mi. of rapids.

Below the Pafuri confluence the Mozambique plain is broken by ridges and *kopjes*; at the confluence of the Olifants the plain is much more even, becoming increasingly flatter toward the coast. The river gradient near the mouth is low, the plain being liable to frequent flooding. The mouth is partially blocked by a sand bar, but a channel about 200 yd. wide and 8 ft. deep at low-water spring tide allows coastal steamers to enter the river at high tide and reach the town of Vila de João Belo (generally known as Chai Chai) without navigational difficulties.

Occupying about one-fifth of the Limpopo basin, its major tributary, the Olifants, enters the Bushveld basin at Loskop, north of Middelburg, where it is dammed. After flowing through the eastern part of the basin floor it turns eastward and cuts successively gorge after gorge through the quartzites and limestone of the eastern margin of the basin and the Transvaal Drakensberg, joining the Limpopo 50 mi. E. of the Lebombo range.

The Limpopo has not been gauged to any considerable extent except in the upper reaches. At the Hartbeestpoort dam the Crocodile headwaters have a mean annual discharge of 124,000 ac.ft. (1 ac.ft. = 43,560 cu.ft.). The flow is at a maximum in February (21,000 ac.ft.) and a minimum in August (4,000 ac.ft.). The dam has an approximate capacity of 136,000 ac.ft., which irrigates about 33,000 ac. around Brits in the Bushveld basin, the main crops being wheat and tobacco. The general regimen of the Limpopo in its middle and lower courses is, however, fairly well known. The maximum flow is generally in February or March, the minimum in August or September. In the winter months the bed may contain a series of pools with little or no connecting flow. Summer floods are sometimes of astonishing proportions, as in 1933 when the peak flow was 505,000 cu.ft. per second.

On the Olifants river the annual discharge at Loskop dam averages about 539,000 ac.ft., the maximum flow being in February (124,000 ac.ft.) and the minimum in September (11,000 ac.ft.). The dam has a capacity of about 167,000 ac.ft. and serves to irrigate about 24,000 ac. of alluvial ground along the river's course. In other parts of the Olifants basin about 14,000 ac. are irrigated by tributaries of the Olifants, including the Zebediela estate where 5,500 ac. of citrus groves are watered by the Gompies river in the northern part of the basin.

In Mozambique the Limpopo is dammed about 100 km. (62 mi.) from its mouth by a barrage about 22 km. (14 mi.) above the village of Guijá, the barrage serving also as a bridge for the Mozambique-Southern Rhodesia railway. The complete Guijá scheme was designed to bring 74,000–99,000 ac. under the furrow, the European plots to be worked by Portuguese labour alone and the African plots by African labour. The scheme was inaugurated in 1955 by the settlement of a pilot nucleus of 50 Portuguese families and 319 African families on the irrigated land. By the end of the 1950s wheat, rice and other crops had been successfully produced. The development of other riparian areas below Guijá was planned.

Though claiming the territory through which it ran, the Portuguese made no attempt to trace the river, which was called Rio do Espiritu Santo by Vasco da Gama in 1497. Capt. J. F. Elton, traveling from the Tati gold fields in 1870, was the first to seek an open road to the sea via the Limpopo. He voyaged down the river from the Shashi confluence to the Tolo Azimé cataract, which he discovered, following the stream thence on foot to the low country. The lower course of the river had been explored 1868–69 by another British traveler, St. Vincent Whitshed Erskine.

See W. Ramke, "Down the Limpopo," *S. Afr. Geogr. J.*, xv (1932). (J. H. Wn.)

LINACEAE, the flax family of dicotyledonous herbs and shrubs, the most important genus of which is *Linum*, comprising cultivated flax and several species of garden plants. See **LINUM**; **FLAX**.

LINACRE, THOMAS (c. 1460–1524), English humanist and physician, founder (1518) and first president of the Royal College of Physicians, was probably born c. 1460 at Canterbury, Kent. Educated at the universities of Oxford and Padua, he was fully imbued with the “new learning” and c. 1501 was called to court as tutor to Prince Arthur. On the accession of Henry VIII he was appointed the king’s physician and he also treated most of the great statesmen and prelates. He made benefactions to medical teaching at Oxford and Cambridge, wrote a Latin grammar and a work on Latin composition and published Latin translations of several of the works of the Greek physician Galen. He died in London on Oct. 20, 1524. An intimate friend of Erasmus, Sir Thomas More, John Colet, William Grocyn and others, Linacre is the prototype of the great scholar physicians of the Renaissance.

See J. N. Johnson, *Life of Thomas Linacre*, ed. by R. Graves (1835). (W. J. Br.)

LINARES, inland province of central Chile. The province was separated from Maule province in 1873, reabsorbed in 1927 and recreated in 1936. Area 3,635 sq.mi. Pop. (1960) 171,302. The province consists of central valley and Andean cordillera terrain, all lying within the Maule drainage system. In the rolling central valley soils are not outstanding, but the province is of major agricultural significance because there is an abundance of water for irrigation. It ranked high in wheat and in wine and flax production, in *chacareria* area (beans, corn, chick-peas, potatoes, peas and lentils), and in rice and sunflower acreage. The San Javier-Villalegre district is noted for its vineyards. Livestock raising (cattle and sheep) is general. Crops are processed and shipped through the market and administrative centres of San Javier (pop. [1960] 8,541), Parral (14,610) and Linares (27,568), the provincial capital. The towns are served by the state railway; at Parral the Cauquenes (Arauco province) branch line begins. The longitudinal highway also traverses the province, and lesser lateral roads lead to spas at Longaví, Panamávida, Catillo and Quinamávida. Although the city of Linares was founded as San Javier de Bella Isla (1755) and renamed Villa de San Ambrosio de Linares (1794), its present name became official in 1875. (J. T.)

LINARES, a town in the province of Jaén, region of Andalucía, southern Spain, lies among the southern foothills of the Sierra Morena, 5 km. (3 mi.) N.W. of the Guadalimar river and 53 km. (33 mi.) N.E. of Jaén by road. Pop. (1960) 60,068 (mun.). Linares is connected by branch railways with the argentiferous lead mines on the northwest, and with the main railways from Madrid to Seville, Granada and the principal ports on the southern coast. Its population is chiefly employed in the lead mines and in the manufacture of powder, dynamite, match for blasting purposes and rope. The mining plant is entirely imported, and smelting, desilverizing and the manufacture of lead sheets and pipes are carried on. Linares lead is unsurpassed in quality. About 0.8 km. ($\frac{1}{2}$ mi.) S. is the village of Cazlona, with remains of the ancient Iberian settlement of Cástulo. The bullfighter Manolete (Manuel Rodríguez) was killed in the bull ring of Linares. (M. B. F.)

LINCOLN, EARLS OF. This English title was first created for WILLIAM D'AUBIGNY, who was created earl of Lincoln about 1139. He soon lost the title and became earl of Sussex, although he is more generally known as earl of Arundel. This creation was much resented by the earl of Chester and his half brother, WILLIAM DE ROUMARE (c. 1096–d. before 1161), both great landholders in Lincolnshire. After they had helped to capture King Stephen at Lincoln in 1141 on behalf of the empress Matilda they changed sides and William was made earl of Lincoln in 1141. The earldom was then granted to GILBERT DE GANT (c. 1120–56) about 1147–48, but on his death the title lapsed. RANULPH DE BLUNDEVILLE (c. 1172–1232), earl of Chester, held the Lincoln earldom from 1217 until 1231 when he resigned it in favour of his sister HAWISE (d. c. 1142) through whom it passed through her son-in-law JOHN DE LACY (c. 1192–1240), into the Lacy family.

HENRY DE LACY (1251–1311), 3rd earl of Lincoln, served Ed-

ward I as both soldier and diplomatist, but under Edward II he joined the baronial opposition led by Thomas, earl of Lancaster, and became one of the ordainers in 1310. He married Margaret, granddaughter of William Longsword, 2nd earl of Salisbury, and his only surviving child, Alice, carried the earldoms of Salisbury and Lincoln to her husband THOMAS (c. 1277–1322), earl of Lancaster. His nephew HENRY (c. 1300–61), earl (afterward duke) of Lancaster, was created earl of Lincoln in 1349, and then the title merged in the crown when his grandson Henry ascended the throne as Henry IV in 1399.

The title was regranted to JOHN DE LA POLE (c. 1462–87), a nephew of Edward IV, who later supported Lambert Simnel, the Yorkist impostor, and was killed at the battle of Stoke, leaving no children. Henry VIII regranted the title to his cousin HENRY BRANDON (1516–34), son of Charles, duke of Suffolk, who also died childless and the title again lapsed. The last creation was for EDWARD CLINTON FIENNES (1512–85), Lord Clinton, who was made earl of Lincoln in 1572 and who managed to serve Henry VIII, Edward VI, Mary I and Elizabeth I without political repercussions or suspicion. The title is still held by his descendants. HENRY (1720–94), 9th earl, succeeded his uncle Thomas Pelham as duke of Newcastle in 1768, and since that time the earldom of Lincoln has been the courtesy title held by the eldest son of the dukes of Newcastle.

LINCOLN, ABRAHAM (1809–1865), 16th president of the United States, was born on Feb. 12, 1809, in a backwoods cabin three miles south of Hodgenville, Ky. When he was two years old he was taken to a farm in the neighbouring valley of Knob Creek. His earliest memories were of this home and, in particular, of a flash flood that once washed away the corn and pumpkin seeds he had helped his father plant. The father, Thomas Lincoln, was descended from a weaver's apprentice who had migrated from England to Massachusetts in 1637. Though much less prosperous than some of his Lincoln forebears, Thomas was a sturdy pioneer. On June 12, 1806, he married Nancy Hanks. The Hanks genealogy is difficult to trace, but Nancy appears to have been of illegitimate birth. She has been described as “stoop-shouldered, thin-breasted, sad,” and fervently religious. Thomas and Nancy Lincoln had three children: Sarah, Abraham and Thomas (died in infancy).

In Dec. 1816, faced with a lawsuit challenging the title to his Kentucky farm, Thomas Lincoln moved with his family to southwestern Indiana. There, as a “squatter” on public land, he hastily put up a “half-faced camp”—a crude structure of logs and boughs, with one side open to the weather—in which the family took shelter behind a blazing fire. Soon he built a permanent cabin, and later he bought the land on which it stood. Abraham helped to clear the fields and take care of the crops but early acquired a dislike for hunting and fishing. In after years he recalled the “panther's scream,” the bears that “preyed on the swine,” and the poverty of Indiana frontier life, which was “pretty pinching at times.” The unhappiest period of his boyhood followed the death of his mother in the autumn of 1818. As a ragged nine-year-old, he saw her buried in the forest, then faced a winter without the warmth of a mother's love. Fortunately, before the onset of a second winter, Thomas Lincoln brought home from Kentucky a new wife for himself, a new mother for the children. Sarah Bush Johnston Lincoln, a widow with two girls and a boy of her own, had energy and affection to spare. She ran the household with an even hand, treating both sets of children as if she had borne them all, but she became especially fond of Abraham, and he of her. He afterward referred to her as his “angel mother.”

This stepmother doubtless encouraged Lincoln's taste for reading; yet the original source of his desire to learn remains something of a mystery. Both of his parents were almost completely illiterate, and he himself received very little formal education. He once said that, as a boy, he had gone to school “by littles”—a little now and a little then—and his entire schooling amounted to no more than one year's attendance. His neighbours later recalled how he used to trudge for miles to borrow a book. According to his own statement, however, his early surroundings provided “absolutely nothing to excite ambition for education. Of course when I came of age I did not know much. Still somehow,

I could read, write, and cipher to the Rule of Three; but that was all." Apparently the young Lincoln did not read a large number of books but thoroughly absorbed the few that he did read. These included Parson Weems's *Life of Washington* (with its story of the little hatchet and the cherry tree), *Robinson Crusoe*, *Pilgrim's Progress* and Aesop's *Fables*. From his earliest days he must have had some familiarity with the Bible, for it doubtless was the only book his family owned.

In March 1830 the Lincoln family undertook a second migration, this one to Illinois, with Lincoln himself driving an ox team. Having just reached the age of 21, he was about to begin life on his own. Six feet four inches tall, he was rawboned and lanky but muscular and physically powerful. He was especially noted for the skill and strength with which he could wield an ax. He spoke with a backwoods twang and walked in the long-striding, flat-footed, cautious manner of a plowman. Good-natured though somewhat moody, talented as a mimic and storyteller, he readily attracted friends. He was yet to demonstrate what other abilities he possessed.

Prairie Lawyer.—After his arrival in Illinois, having no desire to be a farmer, Lincoln tried his hand at a variety of occupations. As a "rail splitter," he helped to clear and fence his father's new farm. As a flatboatman, he made a voyage down the Mississippi river to New Orleans (this was his second visit to that city, his first having been made in 1828, while he still lived in Indiana). On his return he settled in New Salem, a village of about 25 families on the Sangamon river. There he worked from time to time as storekeeper, postmaster and surveyor. With the coming of the Black Hawk War (1832), he enlisted as a volunteer and was elected captain of his company. Afterward he joked that he had seen no "live, fighting Indians" during the war but had had "a good many bloody struggles with the mosquitoes." Meanwhile, aspiring to be a legislator, he was defeated in his first try and then repeatedly re-elected to the state assembly. He considered blacksmithing as a trade but finally decided in favour of the law. Already he had taught himself grammar and mathematics, and now he began to study lawbooks. In 1836, having passed the bar examination, he began to practise law.

The next year he moved to Springfield, the new state capital, which offered much larger opportunities for a lawyer than New Salem did. At first he was a partner of John T. Stuart, then of Stephen T. Logan, and finally, from 1844 on, of William H. Herndon. Nearly ten years younger than Lincoln, Herndon was more widely read, more emotional at the bar, and generally more extreme in his views. Yet this partnership seems to have been as nearly perfect as such human arrangements ever are. Lincoln and Herndon kept few records of their law business, and they split the cash between them whenever either of them was paid. It seems they had no money quarrels.

Within a few years after his removal to Springfield, Lincoln was earning from \$1,200 to \$1,500 annually, at a time when the governor of the state received a salary of \$1,200 and circuit judges only \$750. He had to work hard. To keep himself busy he found it necessary not only to practise in the capital but also to follow the court as it made the rounds of its circuit. Each spring and fall he would set out by horseback or buggy to travel hundreds of miles over the thinly settled prairie, from one little county seat to another. Most of the cases were petty and the fees small.

The coming of the railroads, especially after 1850, made travel easier and practice more remunerative. Lincoln served as a lobbyist for the Illinois Central to assist in getting a charter from the state, and thereafter he was retained as a regular attorney for that railroad. After successfully defending the company against the efforts of McLean county to tax its property, he received the largest single fee of his legal career—\$5,000. (He had to sue the Illinois Central in order to collect the fee.) He also handled cases for other railroads and for banks, insurance companies, mercantile and manufacturing firms. In one of his finest performances before the bar, he saved the Rock Island bridge, the first to span the Mississippi river, from the threat of the river transportation interests who demanded the bridge's removal. His business included a number of patent suits and criminal trials. One of his

most effective and famous pleas had to do with a murder case. A witness claimed that, by the light of the moon, he had seen Duff Armstrong, an acquaintance of Lincoln's, take part in a killing. Referring to an almanac for proof, Lincoln argued that the night had been too dark for the witness to have seen anything clearly, and with a sincere and moving appeal he won an acquittal.

By the time he began to be prominent in national politics, about twenty years after launching upon his legal career, Lincoln had made himself one of the most distinguished and successful lawyers in Illinois. He was noted not only for his shrewdness and practical common sense, which enabled him always to see to the "nub" of any legal case, but also for his invariable fairness and utter honesty.

Private Life.—While residing in New Salem, Lincoln was acquainted with Ann Rutledge. Apparently he was fond of her, and certainly he grieved with the entire community at her untimely death, in 1835, at the age of 19. Afterward stories were told of a grand romance between Abraham and Ann, but these stories lack the support of sound historical evidence. A year after the death of Miss Rutledge, Lincoln was carrying on a half-hearted courtship with Mary Owens. Miss Owens concluded that Lincoln was "deficient in those little links that make up the chain of woman's happiness." She turned down his proposal.

So far as can be known, the first and only real love of Lincoln's life was Mary Todd. High-spirited, quick-witted and well-educated, Miss Todd came from a rather distinguished Kentucky family, and her Springfield relatives belonged to the social aristocracy of the town. Some of them frowned upon her association with Lincoln, and from time to time he too had doubts whether he ever could make her happy. Nevertheless, they became engaged. Then, on a day in 1841 that Lincoln recalled as the "fatal first of January" they broke the engagement, apparently on his initiative. For some time after that, he was overwhelmed by a mood of terrible depression and despondency. Finally the two were reconciled and, on Nov. 4, 1842, were married.

Four children, all boys, were born to the Lincolns. Robert Todd, the eldest and the only one to survive to adulthood, was never very close to his father. Edward Baker was nearly 4 when he died and William Wallace was 11. Thomas, affectionately known as "Tad," outlived his father; Tad, who had a cleft palate and a lisp, was Lincoln's favourite. Lincoln left the upbringing of his sons largely to their mother, who was alternately strict and lenient in her treatment of them.

The Lincolns had a mutual affectionate interest in the doings and welfare of their boys, were fond of one another's company and missed each other when apart, as existing letters show. Like most married couples, the Lincolns also had their domestic quarrels, which sometimes were hectic but which undoubtedly were

BY COURTESY OF CHICAGO HISTORICAL SOCIETY

ABRAHAM LINCOLN'S SPRINGFIELD HOME. NOW PRESERVED AS A MUSEUM BY THE STATE OF ILLINOIS. THE PHOTOGRAPH, TAKEN IN 1860 BY J. A. WHIPPLE, A BOSTON NEWSMAN, SHOWS LINCOLN AND ONE OF HIS SONS IN THEIR FRONT YARD. AND TWO PASSERS-BY

exaggerated by contemporary gossips. Mrs. Lincoln suffered from recurring headaches, fits of temper, and a sense of insecurity and loneliness that was intensified by her husband's long absences on the lawyer's circuit. After his election to the presidency, she was afflicted in spirit by the death of her son Willie, by the ironies of war that made enemies of Kentucky relatives and friends, and by the unfair public criticisms of her as mistress of the White House. She lost all money sense and ran up embarrassing bills. She also put on some painful scenes of wifely jealousy. At last, in 1875, she was officially declared insane, but that was after she had undergone the further shock of seeing her husband murdered at her side. During their earlier married life, Mrs. Lincoln unquestionably encouraged her husband and served as a prod to his own ambition. During their later years together she probably strengthened and tested his innate qualities of tolerance and patience.

With his wife, Lincoln attended Presbyterian services in Springfield and in Washington, but he never joined any church. He once explained: "When any church will inscribe over its altar the Saviour's condensed statement of law and gospel: 'Thou shalt love the Lord thy God with all thy heart and with all thy soul and with all thy mind, and love thy neighbor as thyself,' that church will I join with all my heart." Early in life he had been something of a skeptic and freethinker. His reputation had been such that, as he once complained, the "church influence" was used against him in politics. When running for congress in 1846, he issued a handbill to deny that he ever had "spoken with intentional disrespect of religion." He went on to explain that he had believed in the doctrine of necessity—"that is, that the human mind is impelled to action, or held in rest, by some power over which the mind itself has no control." Throughout his life he also believed in dreams and other enigmatic signs and portents. As he grew older, and especially after he became president and faced the soul-troubling responsibilities of the Civil War, he developed a profound religious sense, and he increasingly personified Necessity as God. He came to look upon himself quite humbly, as an "instrument of Providence," and to view all history as God's enterprise. "In the present civil war," he wrote in 1862, "it is quite possible that God's purpose is something different from the purpose of either party—and yet the human instrumentalities, working just as they do, are of the best adaptation to effect His purpose."

Lincoln was fond of the Bible and knew it well. He also was fond of Shakespeare. In private conversation he used many Shakespearean allusions, discussed problems of dramatic interpretation with considerable insight, and from memory recited long passages with rare feeling and understanding. He liked the essays of John Stuart Mill, particularly the famous one on liberty, but disliked heavy or metaphysical works.

Though he enjoyed the poems of Lord Byron and Robert Burns, his favourite piece of verse was the work of an obscure Scottish poet, William Knox. Lincoln often quoted Knox's lines beginning: "Oh! why should the spirit of mortal be proud?" He liked to relax with the comic writings of Petroleum V. Nasby, Orpheus C. Kerr, and Artemus Ward, or with a visit to the popular theatre.

To the Presidency.—When Lincoln first entered politics, Andrew Jackson was president. Lincoln shared the sympathies which the Jacksonians professed for the common man, but he disagreed with the Jacksonian view that the government should be divorced from economic enterprise. "The legitimate object of government," he was later to say, "is to do for a community of people whatever they need to have done, but cannot do at all, or cannot do so well for themselves, in their separate and individual capacities." He most admired Henry Clay and Daniel Webster among the prominent politicians of the time. Clay and Webster advocated using the powers of the federal government to encourage business and develop the country's resources by means of a national bank, a protective tariff and a program of internal improvements for facilitating transportation. In Lincoln's view, Illinois and the west as a whole desperately needed such aid to economic development. From the outset, he associated himself with the Clay and Webster party, the Whigs.

As a Whig member of the Illinois state legislature, to which

he was elected four times from 1834 to 1840, he devoted himself to a grandiose project for constructing with state funds a network of railroads, highways and canals. Whigs and Democrats joined in passing an omnibus bill for these undertakings, but the panic of 1837 and the ensuing business depression brought about the abandonment of most of them. While in the legislature he demonstrated that, though opposed to slavery, he was no abolitionist. Resolutions were introduced, in 1837, in response to the mob murder of Elijah Lovejoy, an antislavery newspaperman of Alton. Instead of denouncing lynch law, these resolutions condemned abolitionist societies and upheld slavery within the southern states as "sacred" by virtue of the federal constitution. Lincoln refused to vote for the resolutions. Together with a fellow member he drew up a protest against them. This maintained, on the one hand, that slavery was "founded on both injustice and bad policy" and, on the other, that "the promulgation of abolition doctrines tends rather to increase than to abate its evils."

During his single term in congress (1847-49), Lincoln as the lone Whig from Illinois gave little attention to legislative matters as such. He proposed a bill for the gradual and compensated emancipation of slaves in the District of Columbia, but the bill was to take effect only with the approval of the "free white citizens" of the district. It displeased abolitionists as well as slaveholders, and never was seriously considered.

Much of his time Lincoln devoted to presidential politics, to unmaking one president, a Democrat, and making another, a Whig. He found an issue and a candidate in the Mexican War. With his "spot resolutions" he challenged the statement of Pres. James K. Polk that Mexico had started the war by shedding American blood upon American soil. Along with other members of his party, Lincoln voted to condemn Polk and the war while voting supplies for carrying it on. At the same time he laboured for the nomination and election of the war hero Zachary Taylor. After Taylor's success at the polls, Lincoln expected to be named commissioner of the general land office as a reward for his campaign services, and he was bitterly disappointed when he failed to get the job. His criticisms of the war, meanwhile, had not been popular among the voters in his own congressional district. At the age of 40, frustrated in politics, he seemed to be at the end of his public career.

For about five years he took little part in politics, and then a new sectional crisis gave him a chance to re-emerge and rise to statesmanship. In 1854 his political rival Stephen A. Douglas maneuvered through congress a bill for reopening the entire Louisiana Purchase to slavery and allowing the settlers of Kansas and Nebraska (with "popular sovereignty") to decide for themselves whether to permit slaveholding in those territories. The Kansas-Nebraska act provoked violent opposition in Illinois and the other states of the old northwest. It gave rise to the Republican party while speeding the Whig party on the way to disintegration. Along with many thousands of other homeless Whigs, Lincoln soon became a Republican (1856). Before long, some prominent Republicans in the east talked of attracting Douglas to the Republican fold, and with him his Democratic following in the west. Lincoln would have none of it. He was determined that he, not Douglas, should be the Republican leader of his state and section. In their basic views he and Douglas were not quite so far apart as they seemed in the heat of political argument. Neither was an abolitionist, neither a proslavery man. But Lincoln, unlike Douglas, insisted that congress must exclude slavery from the territories. He disagreed with Douglas' belief that the territories were by nature unsuited to the slave economy and that no congressional legislation was needed to prevent the spread of slavery into them. He declared (1858): "'A house divided against itself cannot stand.' I believe this government cannot endure permanently half slave and half free." He predicted that the country eventually would become "all one thing, or all the other." Again and again he insisted that the civil liberties of every U.S. citizen, white as well as black, were at stake. The territories must be kept free, he further said, because "new free states" were "places for poor people to go and better their condition." He agreed with Thomas Jefferson and other founding fathers, how-

ever, that slavery should be merely contained, not directly attacked. In the Lincoln-Douglas debates of 1858, while contesting for Douglas' seat in the United States senate, he drove home the inconsistency between Douglas' "popular sovereignty" principle and the Dred Scott decision (1857), in which the U.S. supreme court held that congress could not constitutionally exclude slavery from the territories. Though he failed to obtain the senate seat, Lincoln gained national recognition and soon began to be mentioned as a presidential prospect for 1860.

On May 18, 1860, after Lincoln and his friends had made skilful preparations, he was nominated on the third ballot at the Republican convention in Chicago. He then put aside his law practice and, though making no stump speeches, gave his full time to the direction of his campaign. His "main object," he had written, was to "hedge against divisions in the Republican ranks," and he counseled party workers to "say nothing on points where it is probable we shall disagree." With the Republicans united, the Democrats divided, and a total of four candidates in the field, he carried the election on Nov. 6. No one in the deep south voted for him, and fewer than 40 out of 100 in the country as a whole. Still, the popular votes were so distributed that he won a clear and decisive majority in the electoral college.

The War Comes.—After Lincoln's election and before his inauguration, the state of South Carolina proclaimed its withdrawal from the Union. To forestall similar action by other southern states, various compromises were proposed in congress. The most important, the Crittenden compromise, included constitutional amendments (1) guaranteeing slavery forever in the states where it already existed and (2) dividing the territories between slavery and freedom. Though Lincoln had no objection to the first of these amendments, he was unalterably opposed to the second, and indeed to any scheme infringing in the slightest upon the free-soil plank of his party's platform. "I am inflexible," he privately wrote. He feared that a territorial division, by sanctioning the principle of slavery extension, would only encourage planter imperialists to seek new slave territory south of the American border and thus would "put us again on the highroad to a slave empire." From his home in Springfield he advised Republicans in congress to vote against a division of the territories. The proposal was killed in committee. Six additional states then seceded and, with South Carolina, combined to form the Confederate States of America.

So, before Lincoln took office, a disunion crisis was upon the country. Attention North and South focused in particular upon Ft. Sumter, in Charleston harbour. This fort, still under construction, was garrisoned by U.S. troops under Maj. Robert Anderson. The Confederacy claimed it and, from other harbour fortifications, threatened it. Foreseeing trouble, Lincoln while still in Springfield confidentially requested Winfield Scott, general in chief of the U.S. army, to be prepared "to either hold, or retake, the forts, as the case may require, at, and after the inauguration." In his inaugural address (March 4, 1861), besides upholding the Union's indestructibility and appealing for sectional harmony, Lincoln restated his Sumter policy as follows: "The power confided in me, will be used to hold, occupy, and possess the property, and places belonging to the government, and to collect the duties and imposts; but beyond what may be necessary for these objects, there will be no invasion—no using of force against, or among the people anywhere." Then, near the end, addressing the absent southerners: "You can have no conflict, without being yourselves the aggressors."

No sooner was he in office than Lincoln received word that the

(CANDIDATE)" PREPARED BY ED-
WARD MENDEL OF CHICAGO FOR THE
CAMPAIGN OF 1860

Sumter garrison, unless supplied or withdrawn, would shortly be starved out. Still, for about a month, Lincoln delayed to act. He was beset by contradictory advice. On the one hand, General Scott, Secretary of State William H. Seward and others urged him to abandon the fort, and Seward through a go-between gave a group of Confederate commissioners to understand that the fort would in fact be abandoned. On the other hand, many Republicans insisted that any show of weakness would bring disaster to their party and to the Union. Finally Lincoln ordered the preparation of two relief expeditions, one for Ft. Sumter and the other for Ft. Pickens, in Florida. (He afterward said he would have been willing to withdraw from Sumter if he could have been sure of holding Pickens.) Before the Sumter expedition got under way, he sent a messenger to tell the South Carolina governor: "I am directed by the President of the United States to notify you to expect an attempt will be made to supply Fort-Sumter with provisions only; and that, if such attempt be not resisted, no effort to throw in men, arms, or ammunition, will be made, without further notice, or in case of an attack upon the Fort." Without waiting for the arrival of Lincoln's expedition, the Confederate authorities presented to Major Anderson a demand for Sumter's prompt evacuation, which he refused. On April 12, 1861, at dawn, the Confederate batteries in the harbour opened fire.

"Then, and thereby," Lincoln informed congress when it met on July 4, "the assailants of the Government began the conflict of arms." The Confederates, however, accused him of being the real aggressor. They said he had cleverly maneuvered them into firing the first shot so as to put upon them the onus of war guilt. Though some historians have repeated this charge, it appears to be a gross distortion of the facts. The facts apparently are these: Lincoln was determined to preserve the Union; to do so, he thought he must take a stand sooner or later against the pretensions of the Confederacy, and he concluded he might as well take this stand at Sumter.

Lincoln's primary aim was neither to provoke war nor to maintain peace. In preserving the Union, he would have been glad to preserve the peace also, but he was ready to risk a war, which he thought would be short.

Commander in Chief.—After the firing on Ft. Sumter, Lincoln called upon the state governors for troops (Virginia and three other states of the upper south responded by joining the Confederacy). He then proclaimed a blockade of the southern ports. These steps—the Sumter expedition, the call for volunteers and the blockade—were the first important decisions of Lincoln as commander in chief of the army and navy. He still needed a strategic plan and a command system for carrying it out.

General Scott advised him to avoid battle with the Confederate forces in Virginia, to get control of the Mississippi river, and by tightening the blockade to hold the South in a gigantic squeeze. Lincoln had little confidence in Scott's comparatively passive and bloodless "Anaconda" plan. He believed the war must be actively fought if it ever was to be won. Overruling Scott, he ordered a direct advance on the Virginia front, which resulted in defeat and rout for the Union forces at Bull Run (July 21, 1861). After a succession of more or less sleepless nights, Lincoln produced a set of memoranda on military policy. His basic thought was this: the armies should advance concurrently on several fronts and should move in such directions as to hold and use the support of Unionists in Missouri, Kentucky, western Virginia and eastern Tennessee. "I state my general idea of this war to be," he later explained, "that we have the greater numbers, and the enemy has the greater facility of concentrating forces upon points of collision; that we must fail, unless we can find some way of making our advantage an overmatch for his; and that this can only be done by menacing him with superior forces at different points, at the same time." This, with the naval blockade, comprised the essence of Lincoln's strategy.

From 1861 to 1864, while hesitating to impose his ideas upon his generals, Lincoln experimented with command personnel and organization. Accepting the resignation of Scott (Nov. 1861) he put George B. McClellan in charge of the armies as a whole. After a few months, disgusted by the slowness of McClellan, he demoted

him to the command of the army of the Potomac alone. He questioned the soundness of McClellan's plans for the peninsular campaign, repeatedly compelled McClellan to alter them, and after the Seven Days' battle before Richmond (June-July 1862) ordered him to give them up. Then he tried a succession of commanders for the army in Virginia—John Pope, McClellan again, Ambrose E. Burnside, Joseph Hooker and George Gordon Meade—but was disappointed with each of them in turn. Meanwhile he had in Henry W. Halleck a general in chief who gave advice and served as a liaison with field officers but who shrank from making important decisions. For nearly two years the Union armies had no very effective unity of command. President Lincoln, General Halleck and War Secretary Edwin M. Stanton acted as an informal council of war. Lincoln, besides transmitting official orders through Halleck, also communicated directly with the generals, sending personal suggestions in his own name. To generals opposing Robert E. Lee, he suggested that the object was to destroy Lee's army, not to capture Richmond or to drive the invader from northern soil.

Finally Lincoln looked to the west for a top general. He admired the Vicksburg campaign of Ulysses S. Grant. Nine days after the Vicksburg surrender (which occurred on July 4, 1863), he sent Grant a "grateful acknowledgment for the almost inestimable service" he had done the country. Lincoln sent also an admission of his own error. He said he had expected Grant to bypass Vicksburg and go on down the Mississippi, instead of crossing the river and turning back to approach Vicksburg from the rear. "I feared it was a mistake," he wrote in his letter of congratulations. "I now wish to make the personal acknowledgment that you were right, and I was wrong."

In March 1864 Lincoln promoted Grant to lieutenant general and gave him command of all the Union armies. At last Lincoln had found a man who, with such able subordinates as William T. Sherman, Philip Sheridan and George H. Thomas, could put into effect those parts of Lincoln's concept of a large-scale co-ordinated offensive that still remained to be carried out. Grant was only a member, though an important one, of a top-command arrangement that Lincoln eventually had devised. Overseeing everything was Lincoln himself, the commander in chief. Taking the responsibility for men and supplies was Stanton, the secretary of war. Serving as a presidential adviser and as a liaison with military men was Halleck, the chief of staff. And directing all the armies, while accompanying Meade's army of the Potomac, was Grant, the general in chief. Thus Lincoln pioneered in the creation of a high command, an organization for amassing all the energies and resources of a people in the grand strategy of total war. He combined statecraft and the over-all direction of armies, with an effectiveness that year by year increased. His achievement is all the more remarkable in view of his lack of training and experience in the art of warfare. This lack may have been an advantage as well as a handicap. Unhampered by outworn military dogma, Lincoln could all the better apply his practical insight and common sense—some would say his military genius—to the winning of the Civil War.

Emancipation.—There can be no doubt of Lincoln's deep and sincere devotion to the cause of personal freedom. Before his election to the presidency he had spoken often and eloquently on the subject. In 1854, for example, he said he hated the Doug-

las attitude of indifference toward the possible spread of slavery to new areas. "I hate it because of the monstrous injustice of slavery itself," he declared. "I hate it because it deprives our republican example of its just influence in the world—enables the enemies of free institutions, with plausibility, to taunt us as hypocrites. . . ." In 1855, writing to his friend Joshua Speed, he recalled a steamboat trip the two had taken on the Ohio river 14 years earlier. "You may remember, as I well do," he said, "that from Louisville to the mouth of the Ohio there were, on board, ten or a dozen slaves, shackled together with irons. That sight was a continual torment to me; and I see something like it every time I touch the Ohio, or any other slave-border."

Yet, as president, Lincoln was at first reluctant to adopt an abolitionist policy. There were several reasons for his hesitancy. He had been elected on a platform pledging no interference with slavery within the states, and in any case he doubted the constitutionality of federal action in the premises. He was concerned about the possible difficulties of incorporating nearly 4,000,000 Negroes, once they had been freed, into the nation's social and political life. Above all, he felt that he must hold the border slave states in the Union, and he feared that an abolitionist program might impel them, in particular his native Kentucky, toward the Confederacy. So he held back while others went ahead. When Gen. John C. Frémont and Gen. David Hunter, within their respective military departments, proclaimed freedom for the slaves of disloyal masters, Lincoln revoked the proclamations. When congress passed confiscation acts (in 1861 and 1862), he refrained from a full enforcement of the provisions authorizing him to seize slave property. And when Horace Greeley in the *New York Tribune* appealed to him to enforce these laws, Lincoln patiently replied (Aug. 22, 1862): "My paramount object in this struggle is to save the Union, and is not either to save or to destroy slavery. If I could save the Union without freeing any slave I would do it, and if I could save it by freeing all the slaves I would do it; and if I could do it by freeing some and leaving others alone I would also do that."

Meanwhile, in response to the rising antislavery sentiment, Lincoln came forth with an emancipation plan of his own. According to his proposal, the slaves were to be freed by state action, the slaveowners were to be compensated, the federal government was to share the financial burden, the emancipation process was to be

gradual, and the freedmen were to be colonized abroad. Congress indicated its willingness to vote the necessary funds for the Lincoln plan, but none of the border slave states was willing to launch it, and in any case few Negro leaders desired to see their people sent abroad.

While still hoping for the eventual success of his gradual plan, Lincoln took a quite different step by issuing his preliminary (Sept. 22, 1862) and his final (Jan. 1, 1863) Emancipation Proclamation. This famous decree, which he justified as an exercise of the president's war powers, applied only to those parts of the country actually under Confederate control, not to the loyal slave states nor to the Union-occupied areas of the Confederacy. Directly or indirectly the proclamation brought freedom during the war to fewer than 200,000 slaves. Yet it had great significance as a symbol. It indicated that the Lincoln government had added freedom to reunion as a war aim, and it attracted liberal opinion in England and Europe to increased support of the Union cause.

Lincoln himself doubted the constitutionality of his step, except as a temporary war measure. After the war the slaves freed by the proclamation would have risked re-enslavement, had nothing else been done to confirm their liberty. Something else was done: the 13th amendment was added to the constitution, and Lincoln played a large part in bringing about this change in the fundamental law. Through the chairman of the Republican national committee he urged the party to include a plank for such an amendment in its platform of 1864. The plank, as adopted, stated that slavery was the cause of the rebellion, that the president's proclamation had aimed "a death blow at this gigantic evil," and that a constitutional amendment was necessary to "terminate and forever prohibit" it. When Lincoln was re-elected on this platform, and the Republican majority in congress was increased, he was justified in feeling, as he apparently did, that he had a mandate from the people for the 13th amendment. The newly chosen congress, with its overwhelming Republican majority, was not to meet until after the lame-duck session of the old congress during the winter of 1864-65. Lincoln did not wait. Using his resources of patronage and persuasion upon certain of the Democrats, he managed to get the necessary two-thirds vote before the session's end. He rejoiced as the amendment went out to the states for ratification, and he rejoiced again and again as his own Illinois led off and other states followed one by one in acting favourably upon it. (He did not live to rejoice in its ultimate adoption.)

Lincoln deserves his reputation as the Great Emancipator. His claim to that honour, if it rests uncertainly upon his famous proclamation, has a sound basis in the support he gave to the antislavery amendment. It is well founded also in his greatness as the war leader who carried the nation safely through the four-year struggle that brought freedom in its train. And, finally, it is strengthened by the practical demonstrations he gave of respect for human worth and dignity, regardless of colour. During the last two years of his life he welcomed Negroes as visitors and friends in a way no president had done before. One of his friends was the distinguished former slave Frederick Douglass. Afterward Douglass wrote: "In all my interviews with Mr. Lincoln I was impressed with his entire freedom from prejudice against the colored race."

Wartime Politics.—To win the war, President Lincoln had to have popular support. The reunion of North and South required, first of all, a certain degree of unity in the North. But the North contained various groups with special interests of their own. Lincoln faced the task of attracting to his administration the support of as many divergent groups and individuals as possible. So he gave much of his time and attention to politics, which in one of its aspects is the art of attracting such support. Fortunately for the Union cause, he was a president with rare political skill. He had the knack of appealing to fellow politicians and talking to them in their own language. He had a talent for smoothing over personal differences and holding the loyalty of men antagonistic to one another. Inheriting the spoils system, he made good use of it, disposing of government jobs in such a way as to strengthen his administration and further its official aims.

The opposition party remained alive and strong. Its membership included war Democrats and peace Democrats, often called

"copperheads," a few of whom collaborated with the enemy. Lincoln did what he could to cultivate the assistance of the war Democrats, as in securing from congress the timely approval of the 13th amendment. So far as feasible, he conciliated the peace Democrats. He gave heed to the complaints of one of them, Gov. Horatio Seymour of New York, in regard to the draft quota for that state. He commuted the prison sentence of another, Congressman Clement L. Vallandigham of Ohio, to banishment within the Confederate lines. In dealing with persons suspected of treasonable intent, Lincoln at times authorized his generals to make arbitrary arrests. He justified this action on the ground that he had to allow some temporary sacrifice of parts of the constitution in order to maintain the Union and thus preserve the constitution as a whole. He let his generals suspend several newspapers, but only for short periods, and he promptly revoked a military order suppressing the hostile *Chicago Times*. In a letter to one of his generals he expressed his policy thus: "You will only arrest individuals and suppress assemblies or newspapers when they may be working palpable injury to the military in your charge, and in no other case will you interfere with the expression of opinion in any form or allow it to be interfered with violently by others. In this you have a discretion to exercise with great caution, calmness, and forbearance." Considering the dangers and provocations of the time, Lincoln was quite liberal in his treatment of political opponents and the opposition press. He was by no means the dictator critics often accused him of being.

Within his own party he confronted factional divisions and personal rivalries that caused him as much trouble as did the activities of the Democrats. True, he and most of his fellow partisans agreed fairly well upon their principal economic aims. With his approval the Republicans enacted into law the essentials of the program he had advocated from his early Whig days—a protective tariff, a national banking system, and federal aid for internal improvements, in particular for the construction of a railroad to the Pacific coast. The Republicans disagreed among themselves, however, on many matters regarding the conduct and purposes of the war. Two main factions arose: the "radicals" and the "conservatives." Lincoln himself inclined in spirit toward the conservatives, but he had friends among the radicals as well, and he strove to maintain his leadership over both. In appointing his cabinet, he chose his several rivals for the 1860 nomination and, all together, gave representation to every important party group. Wisely he included the outstanding conservative, Seward, and the outstanding radical, Salmon P. Chase. Cleverly he overcame cabinet crises and kept these two opposites among his official advisers, until Chase's resignation in 1864.

He had to deal with even more serious factional uprisings in congress. The big issue was the "reconstruction" of the South. The seceded states of Louisiana, Arkansas and Tennessee having been largely recovered by the Union armies, Lincoln late in 1863 proposed his "ten per cent plan," according to which new state governments might be formed when 10% of the qualified voters had taken an oath of future loyalty to the United States. The radicals rejected Lincoln's proposal as too lenient, and they carried through congress the Wade-Davis bill, which would have permitted the remaking and readmission of states only after a majority, not a tenth, had sworn to past, rather than prospective, loyalty. When Lincoln pocket-vetoed that bill, its authors published a "manifesto" denouncing him.

Already he was the candidate of the "Union" (that is, the Republican) party for re-election to the presidency, and the Wade-Davis manifesto signalized a movement within the party to displace him as the party's nominee. He waited quietly and patiently for the movement to collapse, but even after it had done so, the party remained badly divided. A rival Republican candidate, John C. Frémont, nominated much earlier by a splinter group, was still in the field. Leading radicals promised to procure Frémont's withdrawal if Lincoln would obtain the resignation of his conservative postmaster general, Montgomery Blair. Eventually Frémont withdrew and Blair resigned. The party was reunited in time for the election of 1864.

In 1864, as in 1860, Lincoln was the chief strategist of his own

FOUR SCORE AND SEVEN YEARS
AGO OUR FATHERS BROUGHT FORTH
ON THIS CONTINENT A NEW NATION
CONCEIVED IN LIBERTY AND DEDICA-
TED TO THE PROPOSITION THAT ALL
MEN ARE CREATED EQUAL.

NOW WE ARE ENGAGED IN A GREAT
CIVIL WAR TESTING WHETHER THAT
NATION OR ANY NATION SO CON-
CEIVED AND SO DEDICATED CAN LONG
ENDURE. WE ARE MET ON A GREAT
BATTLEFIELD OF THAT WAR. WE HAVE
COME TO DEDICATE A PORTION OF
THAT FIELD AS A FINAL RESTING
PLACE FOR THOSE WHO HERE GAVE
THEIR LIVES THAT THAT NATION
MIGHT LIVE. IT IS ALTOGETHER FIT-
TING AND PROPER THAT WE SHOULD
DO THIS. BUT IN A LARGER SENSE
WE CAN NOT DEDICATE—WE CAN NOT
CONSECRATE—WE CAN NOT HALLOW—
THIS GROUND. THE BRAVE MEN LIV-
ING AND DEAD WHO STRUGGLED HERE
HAVE CONSECRATED IT FAR ABOVE
OUR POOR POWER TO ADD OR DETRACT.
THE WORLD WILL LITTLE NOTE NOR
LONG REMEMBER WHAT WE SAY HERE
BUT IT CAN NEVER FORGET WHAT THEY
DID HERE. IT IS FOR US THE LIVING
RATHER TO BE DEDICATED HERE TO
THE UNFINISHED WORK WHICH THEY
WHO FOUGHT HERE HAVE THUS FAR
SO NOBLY ADVANCED. IT IS RATHER FOR
US TO BE HERE DEDICATED TO THE
GREAT TASK REMAINING BEFORE US—
THAT FROM THESE HONORED DEAD
WE TAKE INCREASED DEVOTION TO
THAT CAUSE FOR WHICH THEY GAVE THE
LAST FULL MEASURE OF DEVOTION—
THAT WE HERE HIGHLY RESOLVE THAT
THESE DEAD SHALL NOT HAVE DIED IN
VAIN—THAT THIS NATION UNDER GOD
SHALL HAVE A NEW BIRTH OF FREEDOM—
AND THAT GOVERNMENT OF THE PEOPLE
BY THE PEOPLE FOR THE PEOPLE SHALL
NOT PERISH FROM THE EARTH.

LINCOLN'S GETTYSBURG ADDRESS AS IT IS INSCRIBED IN GRANITE ON THE WALL OF THE LINCOLN MEMORIAL IN WASHINGTON, D.C. THE SPEECH WAS DELIV-
ERED NOV. 19, 1863 AT CEREMONIES DEDICATING A PORTION OF THE GETTYSBURG BATTLEFIELD AS A CEMETERY FOR THOSE WHO DIED THERE IN THE BATTLE
FOUGHT ON JULY 1, 2 AND 3 OF THAT YEAR

electoral campaign. He took a hand in the management of the Republican speakers' bureau, advised state committees on campaign tactics, hired and fired government employees to strengthen party support, and did his best to enable as many soldiers and sailors as possible to vote. Most of the citizens in uniform voted Republican, and their ballots were a great help to Lincoln. He was re-elected with a large popular majority (55%) over his Democratic opponent, George B. McClellan.

Peace Planning.—In 1864 the Democratic platform called for an armistice and a peace conference, and prominent Republicans as well as Democrats demanded that Lincoln give heed to Confederate peace offers, irregular and illusory though they were. So, in a public letter (July 18, 1864), he stated his own conditions: "Any proposition which embraces the restoration of peace, the integrity of the whole Union, and the abandonment of slavery, and which comes by and with an authority that can control the armies now at war against the United States, will be received and considered by the Executive government of the United States, and will be met by liberal terms on other substantial and collateral points." When conservatives protested to him against the implication that the war must go on to free the slaves, even after reunion had been won, he explained: "To me it seems plain that saying reunion and abandonment of slavery would be considered, if offered, is not saying that nothing else or less would be considered, if offered." After his re-election, in his annual message to Congress, he said: "In stating a single condition of peace, I mean simply to say that the war will cease on the part of the government, whenever it shall have ceased on the part of those who began it." On Feb. 3, 1865, he met personally with Confederate commissioners on a steamer in Hampton Roads. He promised to be liberal with pardons if the south would quit the war, but he insisted on reunion as a precondition for any peace arrangement. In his second inaugural address he embodied the spirit of his policy in the famous words "with malice toward none, with charity for all." His terms satisfied neither the Confederate leaders nor the radical Republicans, and so no peace was possible until the final defeat of the Confederacy.

At the end of the war Lincoln's policy for the defeated South was not clear in all its details, though he continued to believe that the main object should be to restore the "seceded states, so-called," to their "proper practical relation" with the Union as soon as possible. He possessed no fixed and uniform program for the region as a whole. As he said in the last public speech of his life (April 11, 1865), "so great peculiarities" pertained to each of the states, and "such important and sudden changes" occurred from time to time, and "so new and unprecedented" was the whole problem that "no exclusive and inflexible plan" could "safely be prescribed." With respect to states like Louisiana and Tennessee, he continued to urge acceptance of new governments set up under his ten per cent plan during the war. With respect to states like Virginia and North Carolina, he seemed willing to use the old rebel governments temporarily as a means of transition from war to peace. He was on record as opposing the appointment of "strangers" (carpetbaggers) to govern the South. He hoped that the southerners themselves, in forming new state governments, would find some way by which whites and Negroes "could gradually live themselves out of their old relations to each other, and both come out better prepared for the new." A program of education for the freedmen, he thought, was essential for preparing them for their new status. He also suggested that the vote be given immediately to some Negroes—"as, for instance, the very intelligent, and especially those who have fought gallantly in our ranks."

On the question of reconstruction, however, Lincoln and the extremists of his own party stood even farther apart in early 1865 than a year before. Some of the radicals were beginning to demand a period of military occupation for the South, the confiscation of planter estates and their division among the freedmen, and the transfer of political power from the planters to their former slaves. In April 1865 Lincoln began to modify his own stand in some respects and thus to narrow the gap between himself and the radicals. He recalled the permission he had given for the assem-

LINCOLN'S TOMB IN OAK RIDGE CEMETERY, SPRINGFIELD, ILL.

bling of the rebel legislature of Virginia, and he approved in principle—or at least did not disapprove—Stanton's scheme for the military occupation of southern states. After the cabinet meeting of April 14, Attorney General James Speed inferred that Lincoln was moving toward the radical position. "He never seemed so near our views," Speed believed. What Lincoln's reconstruction policy would have been, if he had lived to complete his second term, can only be guessed at.

On the evening of April 14, 1865, John Wilkes Booth shot Lincoln as he sat in Ford's theatre in Washington, and early the next morning he died.

The Living Lincoln.—"Now he belongs to the ages," Stanton is supposed to have said as Lincoln breathed his last. Many thought of him as a martyr. The assassination had occurred on Good Friday, and on the following Sunday, memorable as "Black Easter," hundreds of speakers found a sermon in the event. Some of them saw more than mere chance in the fact that assassination day was also crucifixion day. One declared: "Jesus Christ died for the world; Abraham Lincoln died for his country." Thus the posthumous growth of his reputation was influenced by the timing and circumstances of his death, which won for him a kind of sainthood.

Among the many who remembered Lincoln from personal acquaintance, one was sure he had known him more intimately than any of the rest, and influenced the world's conception of him more than all the others put together. That one was his former law partner, Herndon. When Lincoln died, Herndon began a new career as Lincoln authority, collecting reminiscences wherever he could find them and adding his own store of memories. Though admiring Lincoln, he objected to the trend toward sanctifying the man. He saw, as the main feature of Lincoln's life, the far more than ordinary rise of a self-made man, a rise from the lowest depths to the greatest heights—"from a stagnant, putrid pool, like the gas which, set on fire by its own energy and self-combustible nature, rises in jets, blazing, clear, and bright." To emphasize this point, Herndon gave his most eager attention to evidences of the dismal and sordid in Lincoln's background. An extremely significant event in Lincoln's development, as Herndon viewed it, was a "romance

of much reality" with Ann Rutledge. Lincoln loved no one but Ann and, after her death, never ceased to grieve for her. His memory of her both saddened and inspired him. As for his wife, Mary Todd, she married him out of spite, then devoted herself to making him miserable. So Herndon would have it, and after him countless biographers and novelists and playwrights elaborated upon his views, which persist as accepted knowledge about Lincoln despite their refutation by historical scholarship.

Lincoln has become a myth as well as a man. The legendary is to be sought in imaginative literature and in folklore, in poems, plays, novels, anecdotes and the like. It is also to be found in ostensibly factual productions, including footnoted biographies and histories.

The Lincoln of legend has grown into a protean god who can assume a shape to please almost any worshiper. He is Old Abe and at the same time a natural gentleman. He is Honest Abe and yet a being of superhuman shrewdness and cunning. He is also Father Abraham, the wielder of authority, the support of the weak, and he is an equal, a neighbour and a friend.

Lincoln the man has a reputation which may be considered apart from that of Lincoln the myth. While he was yet alive, this reputation began to grow, and before his death his qualities of greatness already were widely recognized. In the midst of the Civil War, for instance, the *Washington Chronicle* found a resemblance between him and George Washington in their "sure judgment," "perfect balance of thoroughly sound faculties," and "great calmness of temper, great firmness of purpose, supreme moral principle, and intense patriotism." The *Buffalo Express* referred to his "remarkable moderation and freedom from passionate bitterness," then added: "We do not believe that Washington himself was less indifferent to the exercise of power for power's sake." An English newspaper, the *Liverpool Post*, suggested that "no leader in a great contest ever stood so little chance of being the subject of hero worship as Abraham Lincoln," if one were to judge only by the way he looked. His long arms and legs, his grotesque figure, made him too easy to caricature and ridicule. "Yet," this newspaper concluded, "a worshiper of human heroes might possibly travel a great deal farther and fare much worse for an idol than selecting this same lanky American." His inner qualities—his faithfulness, honesty, resolution, insight, humour and courage—would "go a long way to make up a hero," whatever the man's personal appearance.

Among American heroes, Lincoln continues to have a unique appeal for his fellow countrymen and also for people of other lands. This charm derives from his remarkable life story—the rise from humble origins, the dramatic death—and from his distinctively human and humane personality as well as from his historical role as saviour of the Union and emancipator of the slaves. His relevance endures and grows especially because of his eloquence as a spokesman for democracy. In his view, the Union was worth saving not only for its own sake but also because it embodied an

ideal, the ideal of self-government, which was of interest to the people of the entire world. Hence the universality of his continuing appeal.

His best ideas and finest phrases did not occur in impromptu speeches. Rather, his long-remembered sayings were written and rewritten with meticulous revisions ahead of time. Some resulted from a slow gestation of thought and phrase through many years. One of his recurring themes—his central theme—was the promise and the problem of self-government. As early as 1838, speaking to the Young Men's Lyceum of Springfield on "The Perpetuation of Our Political Institutions," he recalled the devotion of his Revolutionary forefathers to the cause, and went on to say: "Their ambition aspired to display before an admiring world a practical demonstration of the truth of the proposition, which had hitherto been considered at best no better than problematical; namely, the capacity of a people to govern themselves." Again and again he returned to this idea, especially after the coming of the Civil War, and he steadily improved his phrasing. In his first message to congress after the fall of Ft. Sumter he declared that the issue between North and South involved more than the future of the United States. "It presents to the whole family of man, the question whether a constitutional republic, or a democracy—a government of the people, by the same people—can, or cannot, maintain its territorial integrity, against its own domestic foes." And finally at Gettysburg he made the culminating, the supreme statement, concluding with the words: "that from these honored dead we take increased devotion to that cause for which they gave the last full measure of devotion—that we here highly resolve that these dead shall not have died in vain—that this nation, under God, shall have a new birth of freedom—and that government of the people, by the people, for the people, shall not perish from the earth."

BIBLIOGRAPHY.—For the general reader, the most usable and valuable guide is Paul M. Angle's *A Shelf of Lincoln Books* (1946). Practically all the known writings of Lincoln himself are available in *The Collected Works of Abraham Lincoln*, edited by Roy P. Basler, 9 vol. (1953-55). A judicious selection from these volumes is reprinted in *The Living Lincoln*, edited by Angle and Earl S. Miers (1955).

Classic multi-volume biographies are John G. Nicolay and John Hay, *Abraham Lincoln: A History*, 10 vol. (1890); Albert J. Beveridge, *Abraham Lincoln, 1809-1850*, 2 vol. (1928); Carl Sandburg, *Abraham Lincoln: The Prairie Years*, 2 vol. (1926), and *The War Years*, 4 vol. (1939); and James G. Randall, *Lincoln the President*, 4 vol. (1945-1955). The best of the one-volume lives is Benjamin P. Thomas' *Abraham Lincoln* (1952).

Matters of controversy and conflicting interpretation are discussed in *Lincoln Reconsidered* (1956), by David Donald, and in *The Lincoln Nobody Knows* (1958), by Richard N. Current. Important works dealing with aspects of Lincoln's statesmanship are David M. Potter, *Lincoln and His Party in the Secession Crisis* (1942); William B. Hesseltine, *Lincoln and the War Governors* (1948); Kenneth M. Stampp, *And the War Came* (1950); and T. Harry Williams, *Lincoln and the Radicals* (1941), and *Lincoln and His Generals* (1952). Ruth Painter Randall writes authoritatively of Lincoln's family life in *Mary Lincoln: Biography of a Marriage* (1953), and *Lincoln's Sons* (1955). Mrs. Randall effectively refutes the views of William H. Herndon, which may most conveniently be found in Herndon's *Life of Lincoln*, edited by Paul M. Angle (1930). An able and realistic treatment of Lincoln's legal career is John J. Duff's *A. Lincoln, Prairie Lawyer* (1960).

(R. N. Ct.)

LINCOLN, a city and county of a city, municipal, county and parliamentary borough, the county town of Lincolnshire, Eng., and the chief town of the Parts of Lindsey, lies 132 mi. N. by W. of London by road. Pop. (1961) 77,068. Lincoln is built on the north side of a gap occupied by the river Witham in the limestone ridge known as the Lincoln edge or cliff. The cathedral stands on the hill and is a landmark for miles, and the town spreads from north of the summit (200 ft.) down the hill and over the flat plain. Fosse way (q.v.) ends at Lincoln, and Ermine street (q.v.) runs through it.

Architecture.—The Newport arch or north gate of Lindum is one of the most interesting pieces of Roman architecture in England. It consists of a carriageway, flanked by two footways, of which one remains, and a west tower with curved segmental front is now exposed. The Roman Ermine street runs through it, leading northward straight to the Humber. Fragments of the town

WINSTON POTE FROM A DEVANEY—PUBLIX

LINCOLN MEMORIAL, POTOMAC PARK, WASHINGTON, D.C., ERECTED BY THE UNITED STATES GOVERNMENT AND DEDICATED MAY 30, 1922. ARCHITECT, HENRY BACON. THE 36-COLUMN COLONNADE REPRESENTS THE STATES EXISTING AT THE TIME OF LINCOLN'S DEATH

wall remain at various points. There is an extensive collection of Roman antiquities from the *colonia* in the City and County museum. Several Roman cemeteries have been discovered; buildings, including baths, an aqueduct pipeline and a public fountain, have been excavated, as have pottery kilns. Of the buildings the most striking is the series of column bases in Bailgate belonging to a portico on the west side of the Roman main street leading to the Newport arch. There is a fine Roman altar to the Parcae in St. Swithin's church found during the building of the church. (I. A. Rb.)

Among churches, apart from the minster, two of outstanding interest are those of St. Mary-le-Wigford and St. Peter-at-Gowts (*i.e.*, sluice gates), both in the lower part of High street. Their towers are probably of mid-11th-century date. Bracebridge church shows similar early work, but as a whole the churches of Lincoln show plainly the results of the siege of 1644.

There were formerly three small priories, five friaries and four hospitals in or near Lincoln. The preponderance of friaries over priories of monks is explained by the fact that the cathedral was served by secular canons. Bishop Grosseteste was the devoted patron of the friars, particularly the Franciscans, who were always in their day the town missionaries. The Grey friary, near St. Swithin's church, is a picturesque two-storied building of the 13th century, now housing the City and County museum. The building known as John of Gaunt's stables, actually St. Mary's guildhall, is of two stories, with Norman doorway and molding. St. Mary's was the leading religious and social guild of the city. The Jew's house is another 12th-century building, and Norman remains appear in several other houses, such as Deloraine court and the house attributed to Aaron the Jew. Among medieval gateways, the Exchequer gate, used by the Lincolnshire Archives committee, is a fine specimen of 14th-century work. Pottergate is of the 14th century, and Stonebow in High street of the 15th, with the guildhall above it. In the Strait lived the Christian boy afterward known as "little St. Hugh," who was asserted to have been crucified by the Jews in 1255. His shrine remains in the S. choir aisle of the minster. Other antiquities are the Perpendicular conduit of St. Mary in High street and the Norman High bridge, carrying High street over the Witham and retaining some 16th-century houses upon it. Among modern buildings is the Usher art gallery, built in 1927, containing the Usher collection of watches, the Peter de Wint collection of oils and water colours, and the Tennyson collection. G. F. Walts's statue of Tennyson stands on the cathedral green.

Lincoln castle, lying west of the cathedral, was newly founded by William the Conqueror when Bishop Remigius decided to establish his minster under its protection. There are Norman remains in the Gateway tower and parts of the walls are of this period; the keep dates from the middle of the 12th century.

(J. W. F. H.; F. T. BA.)

The Cathedral.—Lincoln cathedral contains some of the earliest purely Gothic work extant, as well as every style from the simple massive Norman of the central west front and the later Norman of the west doorways and towers onward through all the Gothic styles, of each of which both early and late examples appear. The building material is the golden oölite and calcareous stone of Lincoln heath and Ancaster, which has the peculiarity of becoming hardened on the surface when tooled. Formerly the cathedral had three spires, all of wood or leaded timber. The spire on the central tower, which would appear to have been the highest in the world, was blown down in 1547. Those on the two western towers were removed in 1808. In 1921 the towers were found to be in imminent danger of collapse and to save them they, with the west transept, Galilee porch and nave, were treated by grouting, the work (with the help of American contributions) being completed in 1932. The peal of 12 bells in the southwest tower, of which four were a World War I memorial to ringers, were lowered 30 ft. and the upper part of the tower was reconstructed with a lantern roof and the lower louvers were closed.

The ground plan of the first church, adapted from that of Rouen, was laid by Bishop Remigius in 1086, and the church was consecrated three days after his death, on May 6, 1092. The

west front consists of an Early English screen (*c.* 1225) thrown over the Norman front, the west towers rising behind it. The earliest Norman work is part of that of Remigius and the great portals and the west towers up to the third story are also Norman (*c.* 1148); the upper parts of them date from 1365 and the Perpendicular windows were inserted about 1450. The nave and aisles were completed about 1220. The transepts, mainly built between 1186 and 1235, have two rose windows: that in the north with contemporary stained glass is Early English, that in the south Decorated—these are called respectively the Dean's Eye and Bishop's Eye. A Galilee of Early English work forms the entrance of the south transept. Of the choir the western portion, known as St. Hugh's (1186–1200), is the famous first example of pointed work; the eastern, called the Angel choir, is ornate work completed in 1280. Perpendicular canopied stalls fill the western part. The great east window, 57 ft. high, is an example of transition from Early English to Decorated (*c.* 1288). Other features of the interior are the Easter sepulchre (*c.* 1300) and the organ screen of a somewhat earlier date. The great central tower is Early English as far as the first story; the continuation dates from 1307. The total height is 271 ft. and the west towers are 206 ft. high. The central tower contains the bell, Great Tom of Lincoln, weighing more than 5 tons.

The buildings of the close that call for notice are the chapter house of ten sides, 60 ft. in diameter, 42 ft. high, with a vestibule of the same height, built about 1225 and therefore the earliest of English polygonal chapter houses, and the library, built by Sir Christopher Wren. The episcopal palace contains work of the date of St. Hugh, and the ruined great hall is mainly Early English. There is some Decorated work and much Perpendicular.

The see covers almost the whole of the county, with very small portions of Nottinghamshire. At its earliest formation, when Remigius, almoner of the abbey of Fécamp, removed the seat of the bishopric there from Dorchester in Oxfordshire in 1072, it extended from the Humber to the Thames, eastward beyond Cambridge and westward beyond Leicester. It was reduced, however, by the formation of the sees of Ely, Peterborough and Oxford, and by rearrangement of diocesan boundaries in 1837. Lincoln cathedral possesses the finest copy extant of Magna Carta (1215); it was exhibited at the New York world's fair, 1939–40, and was afterward sent to the Library of Congress, Washington, D.C., where it remained during World War II. Postwar changes include the rebuilding of the great organ and the establishment (1960) of a cathedral treasury of diocesan plate.

(J. W. F. H.)

History.—The known history of Lincoln begins with the establishment at Lindum by A.D. 47 of the fortress of the 9th legion. After a short tenure by the 2nd legion *Adiutrix* from A.D. 71 onward, the fortress was converted into a *colonia* or settlement for time-expired legionary soldiers. The walls, following the legionary defenses, enclosed a rectangular area of 41 ac., bounded on the north by the Roman gateway of Newport arch, on the west by the west wall of the castle, on the south by the edge of the plateau, and on the east by a line running through the cathedral choir. The town increased in size and early in the 3rd century the western and eastern walls were extended to the south down the hillside almost as far as the river Witham to enclose a second rectangular area of some 56 ac. There was ribbon development along the road to the south across the river, where the railway stations now lie. The Roman enclosures formed the nucleus of medieval Lincoln to which additions were made outside the walls as the population grew. (I. A. Rb.)

The first mention of post-Roman Lincoln is Bede's record that St. Paulinus preached in Lindsey in 628 and built a stone church at Lincoln in which he consecrated Honorius archbishop of Canterbury.

The Danes, in about 877, established themselves at Lincoln, which was one of the five boroughs recovered by King Edmund in 940. Coins were struck there by the Danes in imitation of Alfred pennies and there was a mint from the reign of Edgar to that of Edward I. At the time of Domesday, Lincoln was governed by 12 lawmen, relics of Danish rule, each with hereditary

franchises of sac and soc. The strength of the position of the castle built by William I the Conqueror in 1068 brought much fighting on Lincoln.

In 1141 King Stephen was imprisoned for a short time in the castle by Ranulf, earl of Chester, fighting for the empress Maud. In 1149 Stephen bought the friendship of Ranulf by conceding him, among other territories, the castle and city of Lincoln. King John went to Lincoln in 1200 to attend the obsequies of St. Hugh and while there he received the homage of the king of Scotland. In 1216 the castle stood a siege by the partisans of the French Prince Louis, who were defeated at the battle called Lincoln Fair on May 20, 1217. John de Lacy, nephew by marriage of Ranulf, became the first earl of Lincoln of the Lacy family in 1232 on the death of Ranulf. By the marriage of his descendant, Alice, to Thomas Plantagenet, the castle became part of the future duchy of Lancaster, which was united with the crown on the accession of Henry IV. By the time of the Civil War the defenses had been so neglected that in 1644 the castle was easily taken by the parliamentarians who did a great deal of damage to the city. In 1831 the castle was sold to the counts of Lincoln.

In c. 1157 Henry II gave the citizens their first charter, granting them the city at a fee-farm rent and all the liberties which they had had under William II. In 1200 the citizens obtained release from all but pleas of the crown without the walls, and pleas of external tenure, and were given the pleas of the crown within the city according to the customs of the City of London, on which those of Lincoln were modeled. The charter also gave them quittance of toll and lastage (ship-loading privileges) throughout the kingdom, and of certain other dues. The office of mayor is first mentioned in 1206. In 1275 the citizens claimed the return of writs, assize of bread and ale and other royal rights, and in 1301 Edward I, when confirming the previous charters, gave them quittance of murage, pannage, pontage (taxes or payments for building or repairing town walls, pasturage of swine and maintaining bridges) and other dues. The borough court or moot held weekly meetings in the guildhall from 1272. The mayor and citizens were given criminal jurisdiction in 1327 when the mayor and bailiffs were ordered to hear all local pleas, which led to friction with the judges of assize. The city became a separate county by charter of 1409, when it was decreed that the bailiffs should henceforth be sheriffs and the mayor the king's escheator, and the mayor with four others, justices of the peace, with defined jurisdiction. As the result of numerous complaints of inability to pay the fee-farm rent of £180 Edward IV enlarged the bounds of the county of the city in 1466, while Henry VIII in 1546 gave the citizens four advowsons, and possibly also in consequence of declining trade the city markets were made free of tolls in 1554. A charter was granted by Charles I in 1628 after quo warranto proceedings. It provided for 13 aldermen, 4 coroners and other officers. Lincoln surrendered its charters in 1684, but the first charter was resumed after the revolution of 1688 and was in force till 1835.

Parliaments were held at Lincoln in 1301, 1316 and 1328, and the city returned two burgesses from 1295 to 1885, when it lost one. The county borough now returns one member. After the 13th century the chief interests of Lincoln were ecclesiastical and commercial. As early as 1103 Orderic Vitalis, the chronicler, declared that a rich citizen of Lincoln kept the treasure of King Magnus of Norway, supplying him with all he required, and there is other evidence of intercourse with Scandinavia. There was an important Jewish colony, Aaron of Lincoln being one of the most influential financiers in the kingdom between 1166 and 1186. Made a staple (a town appointed by the king to trade in a certain product) of wool, leather and skins in 1291 and famous for its cloths of scarlet and of Lincoln green in the 13th century, Lincoln had a few years of great prosperity, but with the transference of the staple to Boston early in the reign of Edward III, its trade began to decrease. The craft guilds remained important until after the Reformation, a pageant still being held in 1566. The fair now held during the last whole week of April seems to be the successor of that granted by Charles II in 1684. Edward III authorized a fair from St. Botolph's day to the feast of

SS. Peter and Paul in 1327, Henry IV granted one in 1409 for 15 days before the feast of the Burial of St. Hugh, and William III gave one for the first Wednesday in September.

Industries and Communications.—The principal industry is now heavy engineering: oil engines, excavators, pumps, castings, agricultural machinery and automobile components. The market has a large trade in corn and agricultural produce.

Seven main roads converge on Lincoln and two railway lines pass through it; there are two railway stations. In 1958 Queen Elizabeth II opened Pelham bridge, a fly-over (overpass) to the east of the city, to relieve traffic congestion in High street. The racecourse, to the northwest, is famous for the Lincolnshire handicap; it is owned by the corporation.

See J. W. F. Hill, *Mediaeval Lincoln* (1948), *Tudor and Stuart Lincoln* (1956). (J. W. F. H.)

LINCOLN, city and seat of Logan county, Ill., U.S., is located 29 mi. N. of Springfield. Founded in 1853 and incorporated in 1857, it was named after Abraham Lincoln, then a Springfield attorney, who performed the legal work of the incorporators. Lincoln had tried cases in Postville (the 1835 settlement now part of Lincoln city), and was legislative sponsor of Logan county. Through his influence Lincoln became the county seat.

Situated in an area rich in tillable lands, coal and building materials, it is a shipping point for grains, poultry and dairy products, manufactures, sand and gravel. Manufactures include chinaware, glass containers, cosmetics, store fixtures, metal castings, electrical goods, women's garments and corrugated boxes.

It is the seat of Lincoln college (Presbyterian) chartered in 1865 as Lincoln university, the Lincoln State school for mentally retarded children, the Lincoln Bible institute for theological training, and the Illinois Odd Fellows' Orphans' home.

For comparative population figures see table in ILLINOIS: *Population*. (S. R. K.)

LINCOLN, the capital city of Nebraska, U.S., and seat of Lancaster county, is located 55 mi. S.W. of Omaha in a grain and livestock raising region.

Lincoln came into existence in 1867 as a compromise site for a state capital between two conflicting factions, the North Platters who favoured Omaha and the South Platters who favoured a location south of Salt creek. A commission selected the village of Lancaster in Lancaster county, and renamed it Lincoln after Pres. Abraham Lincoln. This location was also chosen because of the salt basin along Salt creek, but industrial development of the saline deposits never materialized.

The admittance of Nebraska to the union as a state in March 1867, the establishment of Lincoln and the beginning of railroad building in the region were almost simultaneous.

Lincoln was incorporated in 1869 and succeeded in getting its first rail connection, the Burlington and Missouri River line from Plattsmouth, in 1870. It was made a city of the first class in 1887 and became a junction of the Burlington railroad system for the major routes from Chicago to Denver, and from Kansas City to Billings, Mont. Lincoln attracted other railroad connections and by the late 19th century there were 19 different rail routes leading from the city.

A communication hub, Lincoln also developed as a distribution and wholesale centre. Railroads furnished Lincoln with its most important continuing industry through the establishment of major repair and locomotive shops in suburban Havelock. Havelock, University Place, College View and Bethany, previously separate towns, were annexed by Lincoln during 1926-30.

In the early 20th century the political life of Lincoln was dominated by William Jennings Bryan (*q.v.*) who lived there from 1887 to 1921 and published the *Commoner*. A long period of prosperity, growth and civic improvement followed World War I, until the area was hit by the economic depression of the 1930s, aggravated by drought. By the 1940s the agricultural market was again stable, and Lincoln's economy was given an industrial and commercial boost during the World War II period when a number of large business enterprises were established there.

Lincoln also has a large milling and grain storage business and

manufactures industrial rubber V-beltting, agricultural machinery, light self-propelled vehicles, telephone equipment, valves and plumbing supplies, office equipment, dairy and meat products, bricks and pharmaceuticals. The wholesale and jobbing business remained important and the city also became a focus for retail trade. Of added commercial significance was Lincoln's growth as a major insurance centre. A number of federal activities including an air force base and a veterans hospital added to the city's development.

Lincoln early acquired and maintained a position as an educational, cultural and religious centre in the state. The University of Nebraska (founded 1869, state supported), Nebraska Wesleyan university (1887, Methodist), Union college (1891, Seventh-day Adventist) and Cotner School of Religion (1889, Christian Church) are schools of collegiate rank. There is a concentration of state and regional church offices, religious organizations and schools. The Nebraska Art association, the Lincoln Symphony orchestra and the Lincoln Community playhouse are representative of the cultural groups active in the city.

Outstanding on the prairie is the Nebraska state capitol, completed in 1932. A central tower of 400 ft. rises from a massive two-story base. Designed by Bertram Grosvenor Goodhue, it was a pioneer in changing the architectural concepts of the nation in regard to the design of public buildings, holding a place as one of the nation's architectural showpieces. The Nebraska State Historical society building houses an outstanding museum with collections of Indian and pioneer relics.

The population in 1950 was 98,884; in 1960 it was 128,521. The population of the Lincoln standard metropolitan statistical area (Lancaster county) was 155,272 in 1960. For comparative population figures see table in NEBRASKA: Population.

(W. D. A.)

LINCOLN JUDGMENT, an ecclesiastical *cause célèbre* which marked the climax of the ritual prosecutions in the Church of England during the 19th century. It was delivered in 1890 by Archbishop E. W. Benson (*q.v.*), sitting in his own court, which had not been convened since 1699, upon complaints by the Church association against Edward King, bishop of Lincoln, who had committed certain alleged breaches of ritual in the communion service. The judgment, based on a minute historical analysis of ritualistic practices, sanctioned the eastward position of the celebrant, the use of the mixed chalice of wine and water (if mixed before the service), altar lights and the singing of the *Agnus dei*. Manual acts not visible to the congregation and the sign of the cross in the blessing were declared illegal. The fact that Benson ignored previous rulings of the judicial committee of the privy council, making historical tradition the test of validity, meant that ritualists who had previously defied the decisions of secular courts were now prepared to fall into line. The judgment contributed greatly to the ending of the unedifying ritual prosecutions which had dated from the Purchas judgment passed by the judicial committee of the privy council in 1871, but frequently disobeyed because it lacked spiritual authority.

See E. S. Roscoe, *The Bishop of Lincoln's Case* (1891); A. C. Benson, *Life of E. W. Benson* (1899).

(D. H. N.)

LINCOLN PARK, a city of Wayne county, Mich., U.S., is one of Detroit's many residential suburbs. It is grouped with several other communities along the west side of the Detroit river, which are referred to as the "down river communities." The building of the nearby Ford River Rouge plant at Dearborn (*q.v.*) during World War I created a need for many workers' residences.

The alkali industries of Wyandotte (*q.v.*) are nearby and many people from Lincoln Park are also employed there. Lincoln Park was incorporated as a village in 1921 and became a city in 1925. Ecorse and Wyandotte lie between Lincoln Park and the Detroit river.

The population in 1960 was 53,933; for comparative population figures see table in MICHIGAN: Population.

(F. E. L.E.)

LINCOLNSHIRE, a county of eastern England, is bounded north by the Humber, east by the North sea and the Wash, and from south to northwest by Norfolk, Cambridgeshire, Northamp-

tonshire, Rutland, Leicestershire, Nottinghamshire and Yorkshire. The geographical area is 2,664 sq.mi.

Physical Features.—The sinking of exploratory bore holes for coal and oil has shown that geologically Lincolnshire rests on a foundation of Carboniferous rocks. The later overlying sedimentary deposits dip to the east, a factor which determines the bold north-south lines of the county's landscape and the west-east drainage of the ancient rivers. There are two upland areas: in the west the Lincolnshire Limestone, with Northampton Beds below; and in the east the Chalk Wolds. During its passage through the county the limestone escarpment narrows from a broad plateau some 20 mi. in width southwest of Grantham to a ridge only 2 to 3 mi. across north of Lincoln. Prominent breaks in the escarpment occur at three points: in the north the Humber gap; centrally the Lincoln gap, through which the river Witham now flows but which owes its origin to the early Trent before its capture by a tributary of the Humber; and in the south the Ancaster gap which is now dry. The Wolds to the east are 45 mi. long and vary in width from 5 to 12 mi. The western escarpment is steep in the north, rising to 548 ft. near Caistor. The dip slope of the Wolds extends eastward to an old cliff line once overlooking a wave-cut platform which is now thickly covered with Boulder Clay and known as the Marshland. The other major geographical area of Lincolnshire is the Fens (*q.v.*). The coast line in the north is sheltered by the Spurn headland, and quiet conditions allow for the deposition of silt and sand, producing salt marshes and sand dunes with sandy beaches. The easternmost bulge of the coast line from Mablethorpe to Ingoldmells is subject to erosion and is strengthened by massive concrete sea defenses to prevent the inundation of the marshland. After the storms of Jan. 1953 these defenses had to be heavily restored. South of Skegness there is another area of accretion giving rise to sand banks and mud flats that form the Lincolnshire shore of the Wash beyond Gibraltar point.

Lincolnshire is predominantly an agricultural county. There are, however, reminders of the early vegetation. In the southwest, on the Lias Clay, there are still fine woodlands, some now managed by the Forestry commission. In the northwest, relics of the blown-sand heath land still remain, and open pine and birch woodlands that were once so typical of this region are conserved in nature reserves at Scotton common and Linwood warren. The typical calcareous heath lands of the late 18th century with their rabbit warrens and thorn and gorse scrub, on the limestone and chalk uplands, have given place to large arable fields with occasional deciduous woodlands planted to the east and west of the wolds. The Forestry commission has changed the character of the countryside in the north of the county by planting extensive coniferous forests on much of the sandy heath in the neighbourhood of Scunthorpe, Market Rasen and Gainsborough. These alterations have produced widespread changes in the flora and fauna, and since 1948 the Lincolnshire Naturalists' trust, in collaboration with the local authorities and landowners, has achieved much in the field of nature conservation. In the early 1960s there were at least 28 sites of special scientific interest, including 10 nature reserves owned, leased or managed by the trust and 4 over which the trust had consultative agreements with landowners. The Skegness and Gibraltar point nature reserve has a fine bird observatory.

History.—The earliest evidence for human settlement in the county is seen in a widely distributed series of Lower Paleolithic implements found mainly since 1945. Upper Paleolithic people, normally cave dwellers from Derbyshire, occupied open sites in north Lincolnshire during the warmer part of the year, particularly at Sheffield's hill, 3 mi. N. of Scunthorpe. The subsequent Mesolithic settlement was concentrated largely in three regions: north and south of Scunthorpe; the extreme south of the Wolds; and the Sleaford-Grantham area. The most impressive feature of the Neolithic immigration is seen in the fine series of 15 long barrows located on the Wolds. The Bronze Age saw the heaviest settlement in prehistoric times, and in the Early Bronze Age entry into the county appears to have been through the Humber and Wash estuaries. At Tathwell, south of Louth, a

fine group of six round barrows remains. In the Middle Bronze Age, trade links have been proved between the Lincolnshire Wolds and central Europe. Notable Early Iron Age antiquities have come from the river Witham at Lincoln and point to the importance of this site at the crossing of the river and important prehistoric trackways. The most outstanding field monument of this period in the county is the earthwork sited on the limestone plateau at Honington, near Grantham, and known as Honington camp. An extensive Early Iron Age salt industry was developed on the coast round Ingoldmells. There are few areas of Lincolnshire that were not occupied by the Romans. The Ermine street passed right through the county and the Fosse way terminated at Lincoln. Even the fenland was effectively drained by the Lincolnshire and Cambridgeshire Car dykes and became part of the great grain-growing area, the produce of which was carried north in barges along the Car dyke to Lincoln and then via the Foss Dyke canal to the Trent and the north. A vast network of fields and farms in the Fens was revealed by aerial photography. As well as the Roman colony at Lincoln (Lindum colonia), there were important smaller, walled towns at Caistor, Horncastle and Ancaster. Ironstone was smelted by the Romans, and there is evidence of the working of deposits at Scunthorpe and near Grantham. The subsequent Anglo-Saxon invasion was largely along the Humber and into the Wash. Archaeological evidence and place names show that the broad lines of settlement were along the Roman roads.

The three divisions of Lincolnshire are older than the county. The ancient kingdom of Lindsey, known in Anglo-Saxon times as Lindesig—the territory of the Lindissi—had the same boundaries as the modern administrative county of that name, though it was practically an island in early times. Kesteven, south of the Witham, has an Anglo-Saxon name the first element of which means a wood, and it was always a well-wooded district. Holland, so often confused with the common name for the Netherlands, has a different derivation and refers to land overlooked by high ground.

From the 7th and 8th centuries there survives an interesting list of the kings of Lindsey, going back to the 6th and continuing to the end of the 8th century. In the 7th century the supremacy over the kingdom of Lindsey alternated between Mercia and Northumbria. St. Paulinus preached in Lincoln in the 7th century and converted the governor of the city and his household. He built a stone church there: the first recorded Christian church in the county. Kesteven and Holland belonged to Middle Anglia. The Danish invasion of the 9th century swept away many of the Saxon institutions, and by 878 Lincoln and Stamford were included among the five Danish boroughs. The division of the land among Danish settlers, the naming and settlement of villages and the introduction of the Scandinavian tongue had a permanent effect on the county; only Holland remained uninfluenced by this settlement.

In the struggles of the reign of Stephen, castles at Newark and Sleaford were raised by Alexander, bishop of Lincoln, against the king. In the struggles between John and his barons in 1216 Lincoln remained loyal to the king, but after the landing of Louis of France the city was captured by Gilbert de Gant, created earl of Lincoln by Louis. The castle held out successfully against the invaders. After his disastrous march to Swineshead abbey, John journeyed through Sleaford to Newark, where he died, and in the battle called Lincoln Fair in 1217 Gilbert de Gant was captured by the royalists and the city sacked. At the time of the Wars of the Roses the county, because of territorial influence, was mainly Lancastrian, and in 1461 the Yorkist strongholds of Grantham and Stamford were sacked to such effect that the latter never recovered. In the Civil War of the 17th century, Lindsey for the most part declared for the king. Lord Willoughby of Parham was a prominent parliamentary leader, and the Isle of Axholme and the Puritan yeomanry of Holland declared for parliament.

As early as 1295 two knights were returned to parliament for the county and two burgesses each for Lincoln, Grimsby and Stamford. In the 14th century, parliament met several times at

Lincoln and Stamford, the most notable time being at Lincoln in 1301. Grantham was enfranchised in 1463 and Boston in 1552. Under the act of 1832 the county was divided into a northern and southern division each returning two members; in 1868 it returned six members in three divisions and in 1885 seven members in seven divisions. In 1935 Lincolnshire and Rutland were together divided into seven constituencies: Brigg, Gainsborough, Grantham, Holland with Boston, Horncastle, Louth, and Rutland and Stamford.

At the time of the Domesday survey there were between 400 and 500 mills in Lincolnshire, 2,111 fisheries producing large quantities of eels, 361 saltworks, and iron forges at Stow, St. Mary and Bytham. Lincoln and Stamford were flourishing centres of industry, and markets existed at Kirton-in-Lindsey, Louth, Old Bolingbroke, Spalding, Barton and Partney. The early manufactures of the county are all connected with the woolen trade, Lincoln being noted for its scarlet and green cloths in the 13th century, while an important export trade in the raw material sprang up at Boston. The deforestation of Kesteven in 1230 brought large areas under cultivation, and the same period is marked by the growth of the maritime and fishing towns, especially Boston (which had a famous fish market), Grimsby, Barton, Saltfleet, Wainfleet and Wrangle. The Lincolnshire towns suffered from the general decay of trade in the 15th century, but agriculture was steadily improving; and with the gradual drainage of the Fens, culminating in the vast operations of the 17th century, more than 330,000 ac. in the county were brought under cultivation, including more than two-thirds of Holland. The fen drainage resulted in the extinction of many local industries, such as trade in goose feathers and the export of wild fowl to the London markets.

Ecclesiastical History and Architecture.—Lindsey was originally included in the Mercian diocese of Lichfield, but when it was conquered by Egrith of Northumbria about 671 it came under the bishop of York. On the subdivision of the Northumbrian see by Archbishop Theodore in 677, it was made into a separate diocese. There is a list of the bishops of Lindsey from 678 to 869 and again from 953 to 1004. The Danish invasions of the 9th century put an end to the bishopric and to organized ecclesiastical life; monastic foundations which existed at Icanho (perhaps near Boston), Barrow, Bardney, Partney and Crowland as early as the 7th century were destroyed and only Bardney was ever rebuilt. The Middle Anglian diocese had its seat at Leicester but in 877, during the Danish occupation, it was transferred to Dorchester in Oxfordshire, which became the episcopal centre for the whole region and remained so until Bishop Remigius transferred it to Lincoln in 1072.

There are examples of Saxon and Norman architecture in many of the churches. St. Peter's at Barton-upon-Humber is the finest Saxon church, built shortly before A.D. 1000. There is an impressive Saxon tower at Broughton, near Brigg, but the best-known pre-Conquest church is at Stow. The characteristic Saxon-Norman towers, built about the time of the Conquest, are best illustrated at Bracebridge (Lincoln), Marton, Rothwell, Clee and Great Hale. The outstanding example of domestic architecture of this period outside of Lincoln is the manor house at Boothby Pagnell.

At the time of the suppression of the monasteries under Henry VIII there were upward of 100 religious houses, and in the Fens rose some of the finest abbeys held by the Benedictines. The Gilbertines were a pure English order which arose in Lincolnshire. Sempringham, the chief house of the order, was founded by St. Gilbert c. 1135. Barlings (Premonstratensian), northeast of Lincoln, was founded in 1154. The Benedictine Mitred abbey of Crowland existed in 1051. Thornton abbey (Black Canons), with its fine 14th-century brick gatehouse, was founded in 1139 at the same time as Kirkstead where the Cistercian monks built a chapel for lay people outside the precincts. There is a wealth of Early English churches in the county: St. James's, Grimsby, is a good example; Tattershall is typical of the fine Perpendicular churches; and Grantham, Sleaford, Heckington and Crowland of the Decorated style. There are good examples of 15th-century

HUGH BIBLEY

THE WESTERN LANTERN TOWER OF ST. BOTOLPH'S CHURCH, BOSTON, KNOWN AS THE "BOSTON STUMP" (1309-1460)

village churches in the wolds; e.g., at Bag Enderby and Sutterby. Louth church, with one of the finest spires in England, belongs to the later middle ages, and the spire was erected between 1501 and 1515. To this period belongs also the famous "Boston Stump," the tower of St. Botolph's church at Boston. The 15th century is also reflected in the brick castle at Tattershall built by Ralph Cromwell, 1433-55.

Population and Administration.—Lincolnshire is divided into three administrative counties called the Parts of Holland, the Parts of Kesteven and the Parts of Lindsey, each with a county council. Holland, the smallest, covers 418.6 sq.mi. and contains one municipal borough, Boston (pop. [1961] 24,903); one urban and three rural districts; its population in 1961 was 103,388. Kesteven, in the southwest, covers 722 sq.mi. and within it are two municipal boroughs, Grantham (25,030) and Stamford (11,743); two urban districts and four rural districts; its population in 1961 was 135,317. Lindsey, covering 1,523 sq.mi., including the county boroughs of Lincoln (77,065) and Grimsby (96,665), contains three municipal boroughs, Cleethorpes (32,705), Louth (11,556) and Scunthorpe (67,257); nine urban and nine rural districts; its population in 1961 was 504,678. Apart from the industrial areas in the north and northwest, the seaside resorts and a number of market towns, Lindsey is mainly a county of small villages. The provision of adequate schools, village halls, public transport and other amenities is therefore a special problem. By arrangement between the three administrative counties there is a single police force outside Lincoln and Grimsby.

For judicial purposes Lincolnshire lies in the midland circuit of the high court, and the assize town is Lincoln. Separate commissions of the peace are issued for Holland, Kesteven, Lindsey (divided into 6, 5 and 14 petty sessional divisions respectively), Grantham, Grimsby and Lincoln; and separate quarter sessions are held for each of these areas. Lincoln has its own assizes, being a county of a city.

The crown is represented by a lord lieutenant appointed for the entire geographical county and by a high sheriff for the entire county except Lincoln, which elects its own.

At Cranwell, 12 mi. N.E. of Grantham, is the Royal Air Force

college set up in 1920 and officially opened in 1934. It is the training place for permanent commissioned officers. There is also a training station for short-service officers.

The Economy.—Lincolnshire is one of the principal arable counties of England, 80% of the total area being cultivated. The agriculture is highly mechanized. Barley, wheat and oats are the chief grain crops and potatoes the main root crop. Cattle, pigs and sheep are raised in large numbers; the Lincoln Red short-horn has been bred in the county since the middle of the 19th century, and a favourite breed of pig is the Lincolnshire Curly Coat. On the wolds and heaths are flocks of the largest British sheep—the Lincoln Longwool—whose popularity outside the county has increased since World War II. It has been of great value for crossing with Merino in New Zealand, Australia and the Argentine.

One-sixth of the vegetable acreage of England and Wales is in Lincolnshire, and almost one-sixth of the sugar beet. Horticultural crops are predominant in the south of the county round the Wash, while the Spalding area is notable for its bulb fields, especially daffodils and tulips.

In a county of such varied geological structure the surface extraction of minerals is a considerable industry. Ironstone is won from rich beds at several places. The Frodingham ironstone (Lower Lias) is quarried along 7 mi. of its outcrop near Scunthorpe, the Marlstone ironstone (Middle Lias) near Grantham and the Northampton ironstone (Inferior Oolite) at Colsterworth; and there is mining of the Claxby ironstone (Lower Cretaceous) south of Caistor. There are large cement works near Barton-upon-Humber (using chalk) and at Kirton Lindsey (using the Lincolnshire limestone). Building stone from the Lincolnshire limestone has long been famous, the finest quarries being at Ancaster. Clay, sand and gravel are also worked.

At Scunthorpe are some of the largest and most up-to-date iron foundries and rolling mills in Europe, and between 1901 and 1961 the population of the town grew from 9,000 to 67,257 on account of its steel industry. Lincoln, Grantham and Gainsborough long enjoyed an international reputation for the manufacture of agricultural machinery; but the scope of their engineering and other industries has greatly extended. There are smaller but established industries such as milling, brewing, beet-sugar extraction, ropemaking, canning (especially at Boston and Bardney) and oil-cake manufacture at Barton-upon-Humber, Brigg, Boston, Louth, Sleaford and elsewhere. At Immingham on the Humber a deep-water dock was constructed in 1912 and has been extensively used for trading, chiefly in coal, iron, grain, timber and motor vehicles. With the development close by, since 1945, of large chemical and fertilizer factories and an oil refinery, the village is expanding into a small but prosperous town. At Keadby on the Trent an electric power station was put into operation in 1952. Grimsby is the greatest deep-sea fishing port in England and has a numerous fleet of steam trawlers. Boston is a port whose shipping trade with the European continent consists largely of the importing of timber and agricultural produce.

Lincoln was an important meeting place of Roman roads and canals and is now a railway centre. Canals are little used, but the rivers Trent, Witham, Ancholme and the Roman Foss Dyke are navigable by barge. A ferry crosses the Humber from New Holland to Kingston upon Hull in Yorkshire.

The Lincolnshire coast is a popular holiday area for the industrial Midlands, the principal resorts being Cleethorpes, Mablethorpe and Sutton, Chapel St. Leonards, Ingoldmells and Skegness.

LIND, JAMES (1716-1794), Scottish physician, who has been called the "founder of naval hygiene in England," took his M.D. degree at Edinburgh in 1748 and was physician at the Haslar hospital for men of the Royal Navy, Gosport, Hampshire, Eng., from 1758 until his death. When Lind went to Haslar, scurvy was a common disease among sailors, causing more

deaths in the Royal Navy in wartime than did the enemy. As early as 1564 the Dutch had discovered the health advantages of including fresh citrus fruits and juices in the diet of sailors. Lind revived the principle, an admiralty order prescribed the use of lemon juice (1795) and scurvy disappeared from the navy. He also studied typhus, recommending (1758-63) shipboard delousing procedures similar to the techniques used today; suggested the use of hospital ships for sick sailors in tropical ports; arranged (1761-62) for the shipboard distillation of sea water for drinking purposes; and secured many important and beneficial changes in life on board ship. Lind died at Gosport on July 13, 1794. His three classical works are: *A Treatise on the Scurvy* (1754); *An Essay on the Most Effectual Means of Preserving the Health of Seamen in the Royal Navy* (1757); and *An Essay on Diseases Incidental To Europeans in Hot Climates* (1768).

LIND, JENNY (JOHANNA MARIA LIND) (1820-1887), Swedish operatic and oratorio soprano, was born at Stockholm on Oct. 6, 1820. She made her debut in *Der Freischütz* at Stockholm in 1838 and in 1841 studied with Manuel García in Paris. Meyerbeer wrote the part of Vielka for her in his opera *Ein Feldlager in Schlesien*, which she sang in Berlin in 1844, and in 1847 she sang in London the role of Amelia in *I Masnadieri*, written for her by Verdi. She first appeared in London in Meyerbeer's *Robert le Diable* (May 4, 1847); Henry Chorley reported that the town "went mad about the Swedish nightingale." She was remarkable for her vocal control and agility and also for her florid cadenzas. But it was the purity and naturalness of her art that made the greatest impression, and eventually her sincere piety, responsible for these qualities, made her determined for moral reasons to quit the stage. Success in oratorio and recital made it easier for her to do so, and her final stage appearance took place on May 10, 1849, in *Robert le Diable*. The following year she toured the U.S. under P. T. Barnum's auspices, and in 1852 she married her accompanist, Otto Goldschmidt (1829-1907). She and her husband made their home first in Dresden, Ger., and from 1856 in England. In 1870 she appeared in Goldschmidt's oratorio *Ruth* at Düsseldorf, Ger., and in 1875 she led the sopranos in the Bach choir in London, which Goldschmidt had founded. Her last appearance was at a charity concert at Malvern, Worcestershire, Eng., in 1883. From 1883 to 1886 she taught at the Royal College of Music, London. She died at Malvern on Nov. 2, 1887.

See J. Bulman, *Jenny Lind* (1956).

(Wt. S. M.)

LINDBERGH, CHARLES AUGUSTUS (1902-), U.S. aviator, probably the best-known but least understood figure in aeronautical history, the man whose dramatic solo flight across the Atlantic in May 1927 accelerated world-wide interest in aviation. That flight brought him fame, wealth and a great personal tragedy, but in retrospect it stands only as one episode in a career that greatly influenced the development of commercial and military flying.

Lindbergh was born in Detroit, Mich., on Feb. 4, 1902. His early years were spent mostly in Little Falls, Minn., and in Washington, D.C. (His father represented the 6th district of Minnesota in congress for ten years.) His formal education terminated during his second year at the University of Wisconsin, Madison, when his growing interest in aviation led to enrollment in a flying school in Lincoln, Neb., and the purchase of a World War I Curtiss "Jenny," which he flew on barnstorming tours through southern and midwestern states. After a year at the army flying schools in Texas (1924-25), he became an airmail pilot (1926), flying the route from St. Louis, Mo., to Chicago, Ill. During this period he obtained financial backing from a group of St. Louis businessmen to compete for the \$25,000 prize offered by Raymond Orteig for the first nonstop flight between New York and Paris. In the Ryan monoplane "Spirit of St. Louis" he made the flight in 33½ hours on May 20-21, 1927. There followed a series of flights in Europe and America.

In Mexico, Lindbergh met Anne Morrow, daughter of the United States ambassador, Dwight Morrow. They were married on May 27, 1929, at the Morrow home in Englewood, N.J. To-

gether they made flights that took them into many countries of the world. During this period Lindbergh acted as technical adviser to Transcontinental Air Transport and to Pan American Airways, personally pioneering many of their routes.

In March 1932 Lindbergh's two-year-old son, Charles Augustus, Jr., was kidnaped from their home near Hopewell, N.J., and murdered. Partly because of Lindbergh's world-wide popularity, this became the most celebrated crime of the 1930s, and it was a major subject of newspaper attention until April 1936, when Bruno Richard Hauptmann was executed after being convicted of the kidnap-murder. The publicity was so distasteful to the Lindberghs that they took refuge in Europe. After 1936, when he visited German centres of aviation, Lindbergh repeatedly warned against the growing air power of Germany. His decoration by the German government in 1938 led to considerable criticism, as did the neutrality speeches he made in 1940-41 after his return to the United States. Criticism of his public statements by Pres. Franklin D. Roosevelt led Lindbergh to resign his air corps reserve commission in April 1941.

When the United States entered World War II, however, Lindbergh, as a civilian, threw himself unobtrusively into the war effort, serving as a consultant to the Ford Motor company and to the United Aircraft corporation. In the latter capacity he flew 50 combat missions during a tour of duty in the Pacific, and later, after the end of the war in Europe, he accompanied a navy technical mission in Europe investigating German aviation developments.

Following World War II Lindbergh and his family lived quietly in Connecticut. He continued as consultant to Pan American World Airways and to the U.S. department of defense. He was a member of the National Advisory Committee for Aeronautics and served on a number of other aeronautical boards and committees. He received many honours and awards, including the medal of honor (by special act of congress, 1927), the Guggenheim medal and the Wright Brothers Memorial trophy. For his services to the government he was appointed brigadier general in the air force reserve by Pres. Dwight D. Eisenhower in 1954. His book *The Spirit of St. Louis*, describing the flight to Paris, was published in 1953 and gained him a Pulitzer prize. He was also the author of *We* (1929), *Of Flight and Life* (1948) and, with Alexis Carrel, *The Culture of Organs* (1938), concerning researches on which he and Carrel had collaborated.

ANNE MORROW LINDBERGH (1906-) wrote essays and poetry, in addition to accounts of her trips. Her books include *North to the Orient* (1935), *Listen! The Wind* (1938), *Gift From the Sea* (1955) and *Unicorn and Other Poems, 1935-1955* (1956).

LINDE, CARL VON (1842-1934), German engineer, inventor of a process of liquefying gas that is basic to the science of refrigeration, was born at Berndorf, in Bavaria, on June 11, 1842. He attended the Polytechnikum at Zürich, Switz., during 1861-64 and then obtained employment at locomotive works, first in Berlin, then in Munich. In 1868 Linde became assistant professor of machine design at the newly established Technische Hochschule in Munich. A scientific paper published in 1870 dealing with the withdrawal of heat at low temperature by mechanical means decided his life work. Another paper relating to refrigeration followed, and brewers, taking note of the practical value of his studies, financed his development of a methyl-ether refrigerator in 1874. In 1876 he took out his first patent for an ammonia refrigerator. Other refrigeration machines had been in use, but Linde's was the first one based upon precise calculations of efficiency. In 1891 he established an experimental laboratory to study refrigeration and related matters. Utilizing the Joule-Thomson effect, he succeeded in producing liquid air in 1895. A rectifying column devised by Linde produced either fairly pure oxygen or fairly pure nitrogen in a single rectification. Many later developments in this field have used essentially Linde's methods, and modern research in the physics of low temperatures and also of very high vacuum has been made possible by his work. He was raised to the nobility in 1897 and died at Munich on Nov. 16, 1934.

BIBLIOGRAPHY.—C. von Linde, *Aus meinem Leben und meiner Arbeit* (1916); J. H. Awberry, "A Pioneer of Deep Refrigeration," *Nature*, vol. cxlix, p. 630 (June 6, 1942). (W. E. Hd.)

LINDEMANN, (CARL LOUIS) FERDINAND VON (1852–1939), German mathematician, known particularly for his proof that the number π is transcendental, that is, does not satisfy any equation with rational coefficients, was born at Hanover on April 12, 1852. Educated at the universities of Göttingen, Erlangen, Munich, Paris and London, he served as professor of mathematics at the universities at Freiburg im Breisgau, Königsberg and Munich. His mathematical papers were mainly on geometric topics. His famous proof establishes that the classical Greek construction problem of squaring the circle by compass and ruler is insoluble. He died in Munich, March 7, 1939. (O. Oe.)

LINDEN, a city in Union county, N.J., U.S., 18 mi. S.W. of New York city. Because of its metropolitan location, many major companies operate plants there, and manufactures include chemicals, oil, metal products, cars and trucks, aircraft parts, furniture, clothing, and foods and beverages. The town was settled early in the 18th century on four village sites, which combined in 1861 to form the township of Linden, a name chosen to reflect the existence of many linden trees in the area. It was largely a farming centre until local industrialization began around 1900; it was incorporated as a city in 1924.

For comparative population figures see table in NEW JERSEY: Population. (W. L. Ca.)

LINDEN (LIME, BASSWOOD), the common name for deciduous trees of the genus *Tilia* of the family Tiliaceae; native to the north temperate zone, they are widely planted for shade and ornament in urban centres. Lime and linden both have their origin in *lind*, an Old English term for these trees.

The genus *Tilia* includes about 30 species of deciduous trees and a number of natural and well-established hybrids. The lindens are readily recognized by their coarsely toothed, irregularly heart-shaped leaves and their flowers and fruits, borne in clusters at the termination of long stalks suspended from leafy or straplike bracts. Few trees emit greater fragrance when in blossom, and the cream and gold flowers, rich in nectar, attract the honeybee. Linden honey, light in colour, is highly regarded for its food value.

Linden wood, soft yet firm, has been a prime favourite with continental wood carvers for centuries. Many of the best expressions of their art are the exquisite frets and carvings of religious motifs to be found in churches of both the old and new worlds. The inner bark of the lindens is rich in fibre and several species are still cultivated by the Russians for paper, cloth and cordage fibres. The soft inner tissues were used by ancients as an antiseptic for binding and healing wounds.

Several of the lindens acquire great size; one is recorded in Norfolk, Eng., as being 16 yd. in circumference. The famous

linden tree which gave the town of Neuenstadt in Württemberg the name of Neuenstadt an der grossen Linden was nine feet in diameter. Among the many famous avenues of lindens are the Unter den Linden, of Berlin, and the avenue at Trinity college, Cambridge.

The large-leaved linden (*T. platyphyllos*), a large tree often 100 ft. tall, is found over much of Europe, including France, Germany, Belgium, Poland, Spain and Italy, and extends eastward into Greece and the Crimea. The small-leaved linden (*T. cordata*), another tree of commercial proportions, occurs naturally in the Scandinavian countries, thence south to Spain, the Balkans and east to the Crimea and Siberia.

The common and widespread European linden (*T. europaea*) is generally regarded by most taxonomists as being a natural hybrid between the two foregoing species. The Crimean linden (*T. euchlora*) is a well-established hybrid between *T. cordata* and *T. dasystyla*, the latter species a tree of southeastern Europe, the Caucasus and northern Iran. Two Asiatic species, the Japanese linden (*T. japonica*) and Mongolian linden (*T. mongolica*), are locally important timber trees.

Most important of the American species is the American linden or basswood (*T. americana*), a tree of modest proportions that occurs in mixed hardwood forests from New Brunswick to southern Manitoba, thence south to North Carolina and Missouri. Its moderately soft, straight-grained wood of light colour is used in manufacturing venetian blinds, piano keys, luggage, millwork and, especially, cabinets and excelsior. (E. S. Hr.)

LINDENTHAL, GUSTAV (1850–1935), U.S. engineer, was born at Brünn, Aus., May 21, 1850, and was educated there and at Vienna. After some experience in railway and bridge work in Austria and Switzerland, he moved to the United States in 1871. He was engineer at the Centennial exposition, Philadelphia, Pa., 1874–77, and then practised in Pittsburgh as consulting engineer in railway and bridge construction till 1890, when he moved to New York city. In 1902–03 he was commissioner of bridges for the city of New York.

Lindenthal designed and acted as consulting engineer for the steel-arch railway bridge spanning the East river at Hell Gate, which was opened for traffic in March 1917. With its approaches, it is about 3½ mi. in length and at the date of completion contained the longest steel arch in the world (977 ft.). It remains one of the greatest arches of all time; its outline, framed between great masonry towers, produces a monumental composition. Lindenthal died July 31, 1935.

LINDGREN, WALDEMAR (1860–1939), U.S. economic geologist, was born near Kalmar, Swed., on Feb. 14, 1860. His father was a district judge and a member of the Swedish parliament. Lindgren was educated at Kalmar and at the Royal Academy of Mines at Freiberg, Ger., then Europe's foremost school of mining and geology, from which he graduated in 1883. He went to the United States in the same year and, in 1884, began 28 years of continuous service with the United States geological survey (USGS), during which he acquired the varied firsthand familiarity with the ore deposits of the western states that became the cornerstone of his career. His acute observations during those years, interpreted with rare judgment and presented with clarity, made it possible to diagnose from the mineralogy and textures of ores, with an accuracy not before attained, the physical and chemical conditions under which they formed. They established more firmly than before the igneous sources of many of the mineralizing solutions and clarified the methods by which ores were deposited, notably the method of replacement, the importance of which was not appreciated at the time.

Lindgren became chief geologist of the USGS in 1911, but a year later he resigned to become professor of economic geology and chairman of the department of geology at the Massachusetts Institute of Technology. There, during 27 years, he shared with his students his exceptional knowledge of the work of other geologists and the results of his own rich experience. During his last years in the USGS, he wrote *Mineral Deposits* (4th ed., 1933) which became generally recognized as the leading advanced text in its field. Lindgren was the recipient of many honours, in-

JOHN MARKHAM

FRUIT AND FOLIAGE OF LINDEN OR EUROPEAN LIME (*TILIA EUROPAEA*)

cluding membership in the National Academy of Sciences, the presidency (1924) and the Penrose gold medal of the Geological Society of America (1933), and the presidency of the International Geologic congress (1933), and many others. He died at Brighton, Mass., on Nov. 3, 1939. For further discussion of Lindgren's theories of mineralization and additional information about his classification of mineral deposits see *ORE DEPOSITS: Classification and Genesis*. (E. S. BA.)

LINDLEY, JOHN (1799–1865), English botanist, known for his attempts to formulate a natural system of plant classification and for his services to horticulture, was born Feb. 5, 1799, at Catton, near Norwich, where he was educated. On Lindley's going to London in 1819, Sir William Jackson Hooker gave him an introduction to Sir Joseph Banks, who employed him as assistant librarian. In 1820 he published an original *Rosarum Monographia*, with descriptions of new species and drawings executed by himself, and in 1821 *Digitalium Monographia*.

Shortly afterward, while writing the descriptive portion of the *Encyclopaedia of Plants*, he became convinced of the superiority of the "natural" system of plant classification of A. L. de Jussieu, as distinguished from the "artificial" system of Linnaeus followed in that encyclopaedia. This conviction found expression in Lindley's *A Synopsis of the British Flora; Arranged According to the Natural Orders* (1829) and *An Introduction to the Natural System of Botany* (1830).

In 1829 Lindley accepted the chair of botany in University college, London, which he retained till 1860. He was also assistant secretary of the Royal Horticultural society in 1830 and secretary in 1858 and served on many government committees and commissions. He died at Acton, Middlesex, on Nov. 1, 1865.

Lindley's works also include *The Fossil Flora of Great Britain* (with W. Hutton, 1831–37); *Flora Medica* (1838); *Theory of Horticulture* (1840); *The Vegetable Kingdom* (1846); *Folia Orchidacea* (1852–59); and *Descriptive Botany* (1858). He was editor of the *Botanical Register* and *Gardeners' Chronicle*.

LINDLEY, WILLIAM (1808–1900), English civil engineer especially remembered for his work in Hamburg, Ger., was born in London on Sept. 7, 1808. He was engaged on railway work on the continent of Europe and settled in Hamburg as engineer in chief to the Hamburg-Bergedorf railway (1838–60). In May 1842 a great fire raged in Hamburg for three days. Lindley organized strong measures to check its spread, including the blowing up of the town hall, and was afterward appointed consulting engineer to the city, its water board and board of works. He surveyed the burned city and drew up a plan for its complete rebuilding (1842). He constructed a system of sewers, waterworks (1844–48), gasworks (1846), public baths and wash-houses; and planned extensions to the port that were carried out in 1854. For Altona in 1855 he constructed waterworks and gasworks. After 1860 he worked in many other cities—Frankfurt am Main, for which he acted as consulting engineer (1865–79), Warsaw, Pest, Düsseldorf, Galați and Basel. He also carried out works in Heligoland for the British government. Lindley died at Blackheath, London, on May 22, 1900.

See memoir in *Min. Proc. Inst. Civ. Engrs.*, vol. cxvii (1899–1900). (S. B. HN.)

LINDSAY, the family name of the earls of Crawford, chiefs of clan Lindsay. Of great antiquity, the Lindsay family is believed to be connected with the Norman house of Limesay; there is no territorial district of Lindsay in Scotland. The earliest known member of the family is Sir Walter de Lindsia who accompanied David, earl of Huntingdon (afterward King David I of Scotland), when he conquered Cumbria. His descendants divided into three branches whose heads sat as barons in the Scottish parliament for more than 200 years until their chief attained an earldom in 1398. The Lindsays held the great mountain district of Crawford in Clydesdale (from which the name of the earldom derives) from the 12th century to the close of the 15th, when it passed to the Douglas earls of Angus.

See A. W. C. Lindsay, *Lives of the Lindsays*, 3 vol. (1849).

LINDSAY, NORMAN ALFRED WILLIAM (1879–), Australian artist and novelist, was born at Creswick, Vic-

toria, on Feb. 23, 1879. He began to draw for a Melbourne newspaper at 16, and in 1901 moved to New South Wales. He was for many years the chief cartoonist of the *Sydney Bulletin*. His chief characteristics of imaginative power, grim strength and a certain coarseness of style are apparent in his illustrations to Theocritus, Boccaccio, Casanova and Petronius, the best of which were collected in *The Pen Drawings of Norman Lindsay* (1918). Among his other published works are *Redheap* (1931), *Saturdee* (1933), *Pan in the Parlour* (1934), *Age of Consent* (1938) and *The Cousin from Fiji* (1945). He illustrated many books, including his own novel *The Cautious Amorist*, and was joint founder of the Endeavour press. (D. L. FR.)

LINDSAY, (NICHOLAS) VACHEL (1879–1931), U.S. writer, a gifted and original poet notable for his "General William Booth Enters Into Heaven" and similar poems, was born at Springfield, Ill., Nov. 10, 1879. In 1897 he entered Hiram college, in Ohio, but left after three years to study art in Chicago and New York city. He supported himself, in part, by lecturing for the Y.M.C.A. and the Anti-Saloon league. Meanwhile he had turned to the writing of poetry, and for several summers he wandered through the states, reciting his poems in return for food and shelter. His ambition was to convert America to his vision of beauty. "If I put my soul and body without reserve into the hands of the Lord," he wrote in his diary, "my part will be done. Then let them lead or kill or cure me as they will." (Quoted by Edgar Lee Masters in *Vachel Lindsay: a Poet in America*, Charles Scribner's Sons.)

Lindsay's fame began in 1913 when *Poetry* magazine in its fourth issue published his poem on Booth; subsequently it was included in many anthologies and is probably his best-known single work. His poems of this kind, based on the American rhythms of the crowd and the camp meeting, are his best. Audiences for years delighted to hear him perform them as a kind of "higher vaudeville." Much of Lindsay's poetry is visionary and "hieroglyphic," but he understood the leaders of American cults and causes, men like Alexander Campbell (a founder of the Disciples of Christ), Johnny Appleseed, John Peter Altgeld and William Jennings Bryan. The 20 or so poems which audiences demanded so often that Lindsay grew weary of reciting them ("General William Booth," "The Congo," "Bryan, Bryan, Bryan, Bryan" and "The Santa Fe Trail," for example) became a part of the United States poetic heritage. His "Moon-Poems" and others of this phantasmic kind have been forgotten. Lindsay's best work was done by 1920. Of his later volumes of verse, only *The Candle in the Cabin* (1926) contains poems of distinction. Lindsay died on Dec. 5, 1931.

LINDSEY, BENJAMIN BARR (1869–1943), U.S. judge, a pioneer in juvenile court work and first judge of the conciliation court at Los Angeles, Calif., was born in Jackson, Tenn., on Nov. 25, 1869. At the age of 16 he moved to Denver, Colo., and in 1894 was admitted to the Colorado bar. He sponsored legislation establishing the juvenile court at Denver, served as its presiding judge from 1900 to 1927 and made it the model for similar courts throughout the country. His philosophy, now widely accepted, was that the juvenile offender should be under the protection of the state and a ward of the court, that equity rather than criminal procedure should be employed and that treatment of the juvenile's problem rather than punishment should be the objective. From 1939 until his death he served as judge of the conciliation court at Los Angeles, a special court he helped establish to deal with divorce cases where there was some chance to reconcile the parties. He was one of the first to propose a "family court" with integrated jurisdiction over delinquency and divorce. His ardent championship of "companionate marriage," by which he meant practising birth control to prevent parenthood until a

marriage was solidly established, divorce by mutual consent where the marriage had failed and there were no children but no divorce as of right if children were involved, created great controversy and was confused by his critics with the "trial marriage" proposal of Bertrand Russell. Outspoken, at times contentious, he was an implacable foe of political machines and a leading reformer of archaic legal procedures concerning family social problems. He wrote *Problems of the Children* (1903); *The Beast and the Jungle* (with Harvey O'Higgins) (1910); *Children in Bondage* (with George Creel) (1914); *Pan-Germanism in America* (1919); *The Doughboy's Religion* (with Harvey O'Higgins) (1919); *The Revolt of Modern Youth* (with Wainwright Evans) (1925); *Childhood, Crime, and the Movies* (1926); *The Companionate Marriage* (with Wainwright Evans) (1927); *The Dangerous Life* (with Rube Borough) (1931), an autobiography; and many brochures on juvenile delinquency, domestic relations and crime. He died in Los Angeles, March 26, 1943. (H. H. F.)

LINDSEY, an Anglo-Saxon kingdom probably coterminous with the modern district of Lindsey, Lincolnshire, was an area of early Anglian settlement. A genealogical list of its royal house, extending to Aldfrith, who can be identified with a king of this name who attests a charter of Offa of Mercia between 787 and 796, shows that it had kings of its own. One name in the list, Caedbaed, has a British first element, which may suggest some intermarriage with the Britons. About 631 it was subject to Edwin of Northumbria, and Oswald of Northumbria also obtained control there, which was resented by the inhabitants. Before 674 Lindsey had become subject to Wulfhere of Mercia, who lost it to Egfrith of Northumbria in that year; but Wulfhere's brother, Aethelred of Mercia, recovered it after his victory at the Trent in 678, and it probably remained subject to Mercia until the Danish settlement.

The Danes raided Lindsey in 841 and wintered at Torksey in 873. When they settled in northeast Mercia in 877, Lincoln became one of the Five Boroughs (see DANELAW), and Lindsey was probably divided at that time into its three ridings. It seems to have submitted to Edward the Elder in 918. It was raided by the Danes in 993, accepted Sweyn I as king in 1013 and supported Canute when Sweyn died in 1014, thus calling down the vengeance of King Aethelred II. Place names show an intensive Danish settlement, which explains this incident.

After the conversion by Paulinus in about 631, nothing is heard of the church in Lindsey until 677, when Archbishop Theodore created a diocese, with its see at an unidentified Sidnaceaster. This ceased at the Danish settlement, and the religious history of Lindsey becomes obscure. A bishop Leofwine, first recorded in 953, is said by Florence of Worcester to have united the sees of Lindsey and Dorchester-on-Thames in Edgar's reign, and Lindsey remained part of the latter diocese except that it had a bishop of its own, Sigferth, from about 997 to 1004. After the Norman conquest, the see was moved from Dorchester to Lincoln. Lindsey was claimed unsuccessfully by 11th-century archbishops of York as part of their diocese.

See F. M. Stenton, "Lindsey and Its Kings," in H. W. C. Davis (ed.), *Essays in History Presented to Reginald Lane Poole* (1927) and *Anglo-Saxon England*, 2nd ed. (1947). (D. Wk.)

LINDUS (Gr. LINDOS), an ancient and now modern town on the east coast of Rhodes (q.v.). It was one of the three city-states of Rhodes before their union (408 B.C.). Danish excavations (1902-14, resumed 1952) revealed the Doric temple of Athena Lindia on the acropolis, rebuilt in the 4th century B.C. after a fire, propylaea (entrance gates) and a stoa (colonnade); the temple and stoa were partially restored during the Italian occupation of Rhodes. Among other discoveries was a chronicle of the temple compiled in 99 B.C. by a local antiquarian, listing mythical and historical dedications from many parts of the Mediterranean. The acropolis contains a castle built in the 14th century by the Knights of St. John, who also built many houses in the modern town.

See C. Blinkenberg et al., *Lindos* (1931-).

LINE, in mathematics, is an abstraction to which the stroke of a pen only approximates. Euclid defines it as length without

thickness and specifies that the boundaries of a line are points and that lines define the boundaries of a surface. Another classical definition (not in Euclid) regards the line as generated by the motion of a point and, similarly, a surface by the motion of a line. Starting from the other end, a surface can be defined as the boundary of a space, a line as the intersection of two surfaces, and a point as the intersection of a line and a surface or of two lines on one surface.

In modern geometry (at least in English) the term line generally means a straight line (the more general curved line being called a curve) thought of as extended indefinitely both ways; if bounded at one end it is called a half line, if at both ends a segment. Some old-established phrases survive, such as line of force and line of striction, which do not imply straightness. Euclid defines a straight line as one that lies evenly with respect to the points on itself, a phrase that has called for a good deal of exegesis; for Archimedes it is the shortest distance between two points; and another definition, essentially due to Hero of Alexandria, is that a straight line does not change its position when rotated about its two ends. The properties of straight lines that are most fundamental for modern geometers are those that belong to the aggregate of straight lines, rather than to each one, and include the notions that any two points can be joined by a straight line, that no two straight lines can have more than one common point and that two straight lines in one plane either meet in a point or are parallel; all of which are among Euclid's axioms and postulates.

In analytic or algebraic geometry the straight line is represented by one or more equations of the first degree, in plane geometry by a single equation and in solid geometry by two independent equations.

The special study of line geometry deals with the properties of families of straight lines in space that satisfy one or more conditions, such as passing through a given point, meeting or touching a given curve or touching a given surface. See ANALYTIC GEOMETRY; CURVES; CURVES, SPECIAL. (P. Du V.)

LÍNEA, LA (LA LÍNEA DE LA CONCEPCIÓN), a town in the province of Cádiz, Andalusia region, Spain, is situated between Gibraltar and San Roque. Pop. (1960) 59,456 (municipality). La Línea, which derives its name from the *línea* or boundary dividing Spanish territory from the district of Gibraltar, stands on the isthmus of sand forming the eastern arm of the Bay of Gibraltar and is a frontier post and headquarters of the Spanish commandant of the lines of Gibraltar. It has no port and is a modern town brought into existence solely by the British occupation of Gibraltar, which it supplies with fruit and vegetables. The fortifications erected there in the 16th century were dismantled by the British in 1810 to prevent the landing of French invaders. La Línea produces grapes, strawberries, wine, liquor, fish preserves, and cement products. (M. B. F.)

LINEAR PROGRAMING; see MANAGEMENT SCIENCES.

LINE ENGRAVING; see ENGRAVING, LINE.

LINEN MANUFACTURE. Linen includes all yarns spun and fabrics manufactured from flax fibres. For a comparative discussion of flax and other textile fibres see FIBRE.

Flax is one of the oldest textile fibres known and linen manufacture was one of the most extensive of the domestic industries; at the beginning of the modern period it was developed in Russia, Austria, Germany, the Netherlands, Belgium, northern France, Northern Ireland, Scotland and certain parts of England. In the late 18th century, however, the spinning and weaving inventions of Richard Arkwright, James Hargreaves and Samuel Crompton benefited the cotton industry almost exclusively; and the consequent increase in cotton fabric production caused a widespread reduction in the linen industry, beginning in the United Kingdom but quickly spreading over Europe.

In an effort to bolster the industry in France, Napoleon I in 1810 offered a reward of 1,000,000 fr. to the inventor who devised the best system for spinning flax yarn. Philippe de Girard patented a system within a few weeks but failed to make his invention a commercial success in either France or Austria. Meanwhile in England John Kendrew and Thomas Porterhouse had laid

FIG. 1.—DIAGRAM SHOWING THE CARDING OF FLAX

the real foundation of the present industry by developing a successful process from a patent granted to them in 1787, for "a mill or machine upon new principles for spinning yarn from hemp, tow, flax or wool."

Technical difficulties likewise delayed the introduction of factory weaving for many years after the system was fully applied to other textiles, but these were overcome by improvements in spinning and in methods of preparation. A. J. Warden in *The Linen Trade, Ancient and Modern* (1864) states that power was applied on a small scale to the weaving of canvas in London in about 1812 and that in 1821 power looms for weaving linen were started at Kirkcaldy, Scot. In 1824 Maberly and Co. of Aberdeen had 200 power looms erected for linen manufacture in their Broadford factory; the power loom has continued in uninterrupted use there ever since and the company may be considered the effective introducers of power-loom weaving in the linen trade. Hand-loom weaving has virtually disappeared as a manufacturing method, but in Northern Ireland fine damask cloths continue to be hand-woven for such special occasions as the coronation of Queen Elizabeth II.

Much of the apparel and household linen used in the United States and Great Britain is manufactured in Northern Ireland, with lesser amounts from Belgium, Czechoslovakia, Japan and elsewhere.

YARN MANUFACTURE

Flax fibre is separated from the woody portion of the stem by retting, breaking and scutching; for an explanation of these processes see *FLAX*. The flax scutching machine yields long fibre, which consists of fibre strands in a roughly parallel state called line, and short fibre which consists of partly broken and tangled strands called tow. The three basic operations in yarn manufacture are hackling and spreading, for line fibre, or carding, for tow; preparing; and spinning.

Hackling and Spreading.—The scutched line fibre in stricks (or bundles) of about 30 in. in length is carefully combed during the hackling operation in order to remove broken and tangled fibres and to subdivide the gross fibre strands into finer units. The broken and tangled fibres separated out in the process are called machine tow. The hackling machine was almost completely mechanized in the early 1900s and the principles of the early machine have remained largely unchanged ever since; hand hackling, as a means of commercial production, has completely disappeared.

The hackled line fibre may be produced as a sliver by automatically spreading and overlapping each piece of flax with another on a slow-moving belt, and passing these through a drawing operation as described in the section on preparing (see below). Alternatively, this spreading operation may be carried out by hand; both methods are in everyday use.

The spreadboard sliver produced in either of these two ways is the starting point for the manufacture of yarns suitable for

weaving into sheeting, pillowings, handkerchiefs, damask cloths, drill suitings, cambrics and lightweight fabrics, as well as the finer quality linen threads, twines and netting.

Carding.—The fibre removed as tow from the strick of flax during the scutching and hackling processes is identical in many ways with the line fibre, from which it has been derived. The main differences lie in the shorter length and tangled state, and these differences prevent the tow fibre from being formed into a sliver by a spreading process. The flax card straightens the tow fibres by a combing action, rejects remaining impurities, such as woody material from the stem of the flax plant, and converts the fibre into a continuous sliver. It is similar in general principles to the jute card (see *JUTE*) but has more rollers for combing and cleaning and a greater density of pins on the rollers. The sliver produced by the card may be combed further if required, or passed directly to the preparing system. The carded or combed tow sliver is the starting point for the manufacture of yarns suitable for dress linens, toweling, interlinings, canvases and other heavier fabrics.

Preparing.—The preparing process is essentially the same for both line and tow fibre and the basic principle is the use of pins to penetrate the sliver and control fibre movement during the drawing process. This process takes place between two sets of rollers. The drafting rollers are driven at a surface speed of from 4 to 30 times the speed of the retaining rollers and between these pairs of rollers the sliver is held in pins set in bars which are moved at a slightly faster forward speed than the retaining rollers. The pins separate the sliver into a number of units, from which the drafting rollers draw out fibres. The friction exerted by the pins prevents those fibres not gripped by the drafting rollers from being carried forward out of turn. The relatively fine slivers produced at the drafting rollers are usually doubled together in sandwich fashion by passing them over a perforated guide plate and delivering them as a composite sliver through a pair of rollers to a sliver can, which rests on a turntable driven so as to coil the sliver neatly into the can. The drawing and doubling operation is repeated three to six times depending on the type of fibre and the end product required. The pins on the faller bars also vary in number according to the material used and the stage of processing. As few as eight pins per inch may be used at the early part of a coarse system of drawing, and as many as 40 pins per inch at the later part of a fine system. The spacing, or pitch, of the faller bars and the number employed also vary; the pitch may be as wide as $\frac{5}{8}$ in. in a coarse system and as fine as $\frac{3}{16}$ in. in a fine system. The number employed is specified as the length of the faller bed between the two pairs of rollers; this may be as long as 30 in. when dealing with line fibres or as short as 6 in. when dealing with tow fibres. The quality of the final product is dependent on the skilful use of this pin-controlled drawing system.

The sliver must finally be presented in a form suitable for spinning, and in most cases it is necessary for it to be held to-

FIG. 2.—DIAGRAM SHOWING THE PREPARING OF FLAX

gether lightly with twist. This is done on a frame which carries out the final drafting operation and, by means of a positively driven spindle, inserts twist in the sliver, at the same time winding it onto a suitable bobbin, which is also positively driven. The bobbin and spindle are connected through an ingenious differential-drive mechanism, which ensures that the twisted sliver, called rove, is accurately wound under precise conditions without strain. The bobbins of rove and, in some cases, cans of sliver are then ready for spinning.

Spinning.—This process may be carried out dry on rove or sliver, or wet on rove; the finer yarns are usually wet spun and the coarser yarns dry spun. The wet-spinning frame is equipped with a trough of heated water, through which the rove is passed to two pairs of drawing rollers set in an almost vertical plane and spaced from $1\frac{1}{2}$ to 4 in. apart, depending on the type of yarn being spun. There is no positive control of the fibre in the space or "reach" between the two pairs of rollers, the control being achieved by selecting spacings and twists suitable for the individual fibres and roves. The function of the hot water is to soften the binding materials in the flax strands and so make it possible to draw out from them ultimate fibres and small groups of ultimate fibres. These are then twisted together into a compact mass as they emerge from the drafting rollers and are wound onto a package. Spinning frames of the older type employed spindles or flyers to insert the twist and wind the yarn onto small wooden bobbins, but modern machines are fitted with ball-bearing spindles, stainless-steel rings and nylon travelers to achieve the same object, making possible the use of larger packages and metal bobbins, at much increased speeds of production. The old practice of winding the wet yarn into hanks and drying it in lofts has virtually disappeared and the yarn may now be dried directly on the spinning bobbin in special machines, and wound into a large package of about 3 lb. weight on modern high-speed cone- or cheese-winding machines at about 600 yd. per minute. An alternative method, also in use, is to wind the wet yarn into a package and dry the package on specially designed machines. Both methods reduce handling costs and present the yarn in a form immediately suitable for the processes that follow.

Dry spinning of flax is carried out from sliver on spinning frames with a drafting control system based on faller bars and pins, as used in preparing, and also on frames in which the drafting control is provided by an apron and rollers. The latter is a modern development, using the ring and traveler system for twist insertion and winding on, and was rapidly finding favour in the 1960s as it allowed the yarns to be more economically and better spun. As these sliver-spinning frames use the fibre strands without further splitting, they are limited to the production of the coarser-count yarns. With a pin-controlled drafting frame, a damping roller is generally provided between the drafting roller and the bobbin of yarn, so that the fibres are damp when the twist is inserted and bind together better in the yarn. Dry spinning is also carried out from rove, using machines which rely on a system of stationary guides for control of the fibres in the drafting zone between the two sets of rollers. Although good results can be obtained using these frames, they were largely being replaced in the 1960s by those with apron and roller control, on grounds of both quality and economy in production.

Wet spinning produces a more compact and uniform yarn than dry spinning and is therefore the method commonly employed for all the finer yarns, and those in which the maximum strength must be realized, or a uniform smooth yarn produced. Dry spinning is a cheaper process but

produces a more irregular yarn, which is often hairy in appearance; this is ideally suited for coarser yarns where uniformity is not necessary and, indeed, some degree of unevenness in appearance is often desirable.

The common measure of yarn in both wet and dry spinning is the lea or cut of 300 yd. With wet spun yarns and with most Northern Irish yarns the size or weight is specified as a count of the number of leas which will weigh 1 lb.; for example 16s lea yarn, 16×300 yd., will weigh 1 lb. With coarser yarns, and the majority of yarns from Scotland where much of the heavier trade is situated, the yarn is specified by the weight in pounds of 48 cuts which is called a spyndle. A so-called three pound yarn means that 48×300 yd. of it will weigh 3 lb.; a 16s lea yarn and a 3 lb. yarn are the same size and weight.

Linen thread is prepared from the various counts of fine bleached or boiled line yarn by twisting together a number of individual yarns or strands, two, three, four or six cord, as the case may be, on a doubling spindle similar in principle to the yarn spinning frame, excepting, of course, the drawing rollers. A large trade in linen thread has been created by its use in the machine manufacture of boots and shoes, saddlery and other leather goods, and in heavy sewing-machine work generally. Fine cords, net twine and ropes are also twisted from flax.

Man-Made Fibres.—The manufacturing process evolved for flax is ideally suited for the processing of all types of man-made fibres, provided they are supplied with a minimum amount of crimp and the correct fibre dressing. Fibre lengths in use range from $1\frac{1}{2}$ to 8 in., the short fibre being used to produce slub or fancy yarns, but the flax system will produce level yarns from fibres of 3 to 4 in. upward in length. The flax card is used as the starting point; cut staple fibre processes well on the card, which is remarkable for the gentle way it treats the fibres, forming into a sliver with very little breakage. The pin-controlled drafting process described in preparing (see above) is the best way of controlling the relatively long fine fibres, which are the most suitable for the economic production of strong level yarns. Modern dry-spinning machines produce both blends of yarns and yarns of a single fibre type of very good quality at a reasonable cost. Wet-spinning methods allow a variety of blends of man-made fibres and flax to be produced which are of interest for their special properties.

The flax manufacturing system tends to produce lean compact yarns that make fabrics well suited for household and other similar uses but not suited for clothing. This limitation was overcome by the use of the thermoplastic properties of man-made fibres, so as to develop open-structured yarns suitable for clothing fabrics. Yarns now spun on the flax system are finding an increasing variety of end uses.

The first man-made fibre to be spun on a large scale by this process was viscose rayon; this was followed by acetate, triacetate, polyester, polyamide, polyacrylic and polyolefin fibres.

FABRIC MANUFACTURE

Weaving.—The various operations connected with linen weaving, such as winding, warping, sizing, beaming and drawing-in, are similar in essential features to processes used in cotton weaving; neither is there any significant modification in the looms employed. (See COTTON MANUFACTURE: Production of Fabrics.) Sizing is a matter of importance in the preparation of linen warps for weaving. The sheet of yarn is treated with a film-forming paste of starch and lubricant, applied by flannel-covered rollers, the lowest part of which are submerged in a trough of size paste as they revolve. The size paste is distributed uniformly on the yarn by brushing, and dries to a thin film on the yarn by passing the sheet over fan heaters and steam-heated cylinders, before it is finally wound on the beam for drawing-in and weaving.

Bleaching.—Mechanically and chemically the methods used for bleaching linen resemble closely those used for bleaching cotton, and they require similar care and skill to reduce the amount of nonfibrous impurity to a level which readily enables the required degree of whiteness to be obtained. The process begins

D. A. DERRETT-SMITH

FIG. 3.—DIAGRAM SHOWING THE SPINNING OF FLAX

with a thorough boiling in alkaline liquor, followed by neutralization in a weak acid liquor. Bleaching itself depends on the action of weak solutions containing oxidizing agents, such as hypochlorite, hydrogen peroxide, sodium chlorite, chlorine or chlorine dioxide. The bleaching sequences are controlled to give the desired degree of whiteness.

Impurities in the flax fibre—adhering tissue and gummy impurities, with traces of highly coloured waxy materials from the brownish-green skin of the plant—amount to about 25% of the raw fibre, compared with 5%–10% in cotton. Compact, closely woven white fabrics with a full handle—those used for clothing and embroidery linens, for example—can be more easily produced by weaving from bleached yarn. The yarn is mostly bleached in compact cross-wound packages on perforated centres which are mounted in special package bleaching machines, designed so that the scouring and bleaching liquors can be circulated through the layers of yarn. The weight and construction of linen fabrics woven from unbleached (gray) yarn vary greatly and the mode and duration of bleaching must be adjusted to each quality. Flax fibre is sometimes bleached before spinning. There are advantages in doing this when the fibre will be blended with other fibres. (See also BLEACHING.)

Fabrics.—Linen fabrics are widely different in their qualities, appearance and the uses to which they can be put, ranging from heavy canvas to the most delicate cambrics. The most important of the heavier manufactures are canvas, tarpaulin and carpet backing. The medium weights of linen are used principally for toweling, linings, curtains and upholstery, apparel fabrics, sheeting and embroidery fabrics. Damask for table linen is made in both the single or five-leaf damask and double or eight-leaf damask, the pattern being formed by the intersection of warp and weft yarns at intervals of five and eight threads of yarn respectively. Double damask allows the introduction of more detail in design than single damask. The fine linens are cambrics, sheers and handkerchiefs. Printed and dyed linen fabrics may also be considered a special class, which embraces a variety of weights, textures and finishes, as well as of patterns and colours, since linen is of increased importance for women's dress fabrics.

Linen fabrics are generally of an excellent quality and have several advantages, resulting principally from the structure of the flax ultimate fibre. The cloth is smooth and lustrous, strong and long-lasting; it is lint-free and highly absorbent but dries quickly; it is clean, cool and launders beautifully.

LINEN TRADE DEVELOPMENTS

A number of factors affected the linen industry in the 20th century, especially during the decade of the 1950s. Competition greatly increased from man-made fibres, offering not only lower prices but also claims of "crease resistance" and "wash and wear" for apparel fabrics. Competition within the industry also increased as Belgium and Japan began to produce lower-priced linen. The change in living habits also significantly affected the market for linen; although worldwide, this change has been particularly notable in the United States, where paper tissues have reduced the use of fabric handkerchiefs, paper towels curtailed the use of linen towels and the trend toward informal living has reduced the demand for elegant table and household linens.

A number of developments took place to meet these new conditions. The industry in Northern Ireland consolidated its position with mergers of individual processors within a group. New processes were developed for making linen crease-resistant by the use of suitable resins.

Much diversification took place in the industry. Even before World War II some linen weaving capacity was diverted to the manufacture of cotton and rayon damask tablecloths; Japan emerged as a dominant competitor in this type of product. Northern Ireland also became the centre of a substantial man-made fibre and fabric manufacturing industry, and the complementary properties of flax and man-made fibres are being used in blend fabrics, e.g., flax with acrylic, polyester and triacetate fibres.

Another significant development was the expansion of the U.S.S.R. in the field of linen manufacture. Measured in terms

of flax production, it produced 157,000 tons in 1953 and 430,000 tons in 1958. Production for 1961 was 397,000 tons, compared with about 100,000 tons for the western world.

LINE SPECTRA: see SPECTROSCOPY.

LING (*Molva molva*), a food fish of the cod family (Gadidae), elongate in form, with strong canine teeth in the lower jaw that are arrow-shaped and movable; it has a short first dorsal fin, long second dorsal and anal fins, and a rounded caudal fin. A cold-water fish, ranging from Greenland and Spitsbergen to the Bay of Biscay, the ling lives at depths of 80–150 fathoms. It is a fish eater, and reaches a length of up to seven feet.

In North America several other marine fishes are sometimes called ling, especially western Atlantic members of the genus *Urophycis* and the Pacific greenling (*Ophiodon elongatus*). See also FISH: *Survey of the Bony Fishes*. (L. A. Wd.)

LING is another name for the common heather, a low evergreen shrub native to the open woods of western Europe and the British Isles, and introduced into eastern North America. See HEATHER; ERICACEAE.

LINGUA FRANCA is an auxiliary or compromise language used between peoples speaking mutually incomprehensible vernaculars. It may be one of a number of native languages like Swahili in east Africa, Hausa in west Africa, and Hindustani in India; or it may be a mixed jargon like the pidgin English of the western Pacific or the Sabir (a mixture of French, Italian, Spanish, Greek and Arabic) of the Mediterranean ports.

The term lingua franca was perhaps first applied to a jargon based on southern French and Italian which crusaders and traders developed in the eastern Mediterranean during the middle ages. Extension of trade routes, overseas colonization and slavery, during and after the Renaissance, gave rise to a number of mixed contact jargons like Indo-Portuguese (Ceylon), Annamito-French (Cochin China), Spanish Papiamentu (Curaçao) and several varieties of pidginized English—all based on the languages of the colonizing nations.

Origin.—Such jargons generally begin as a compromise between two groups, each desiring to communicate, but unwilling or unable to learn the language of the other. The European may try to make himself understood by imitating the native's effort to speak the European language. The native, taking this imperfect imitation as a model, tries to reproduce it as best he can with the pronunciation and some of the grammatical structure of his own language, thus giving the European further distortions to imitate—and so on, until a new compromise language is developed. In plantations, slaves from mutually unintelligible tribes got their model from infrequent contacts with European masters and used their vague impressions of their masters' language as a basis of a lingua franca for communication among themselves.

Spread.—The more polyglot an area, the better the chance for a lingua franca to spread. Thus Beach-la-mar or Sandalwood English became an important language in Melanesia where neighbouring villages might speak distinctly different languages; but not so in Polynesia where many dialects are mutually intelligible. Lin-

guistic diversity in the American northwest was largely responsible for the spread of the Chinook jargon, a lingua franca based on Chinook and other American Indian languages, with English admixture. It became the trade language used not only between white traders and Indians but also between different Indian tribes, and for a time it was the native language of the offspring of Oregon squaws and French-Canadian *voyageurs*.

When such jargons supplant the mother tongue they become known as Creole languages. Examples of these are Haitian French Creole, Cape Verde Portuguese, and Taki-Taki, a language developed out of a jargonized English used by the African slaves of English and Portuguese landholders who settled in Dutch Guiana in the middle of the 17th century.

Some contact vernaculars may thus develop into written and standardized national languages. Malay, a compromise of various Malayo-Polynesian languages, was used as a lingua franca in British Malaya and the Dutch East Indies and later became the national language of the Republic of Indonesia.

(W. F. MY.)

LINGUET, SIMON NICOLAS HENRI (1736–1794), French journalist and lawyer whose delight in taking the view opposed to everyone else's made him many enemies, was born in Reims on July 14, 1736. His early writings include *Histoire du siècle d'Alexandre le Grand* (1762), in which he declared that Nero caused far fewer deaths than Alexander, and *Le Fanatisme des philosophes* (1764), a violent attack on the most widely held doctrines of the Enlightenment. Admitted as an advocate in the Paris parlement in 1764, Linguet defended the chevalier de La Barre (J. F. Lefebvre), who was condemned to death on charges of blasphemy and sacrilege in 1766. His greatest masterpiece of pleading was his *Mémoire* of 1772 on behalf of the comte de Morangès (J. F. C. de Molette), accused of trying to defraud his creditors.

Linguet's attacks on other lawyers, on Pierre Gerbier in particular, led to his expulsion from the bar in 1775. He went into exile, traveled in Switzerland, Holland and England and launched the *Annales politiques, civiles et littéraires du XVIIIème siècle* (1777–92). Soon after his return to France he began an attack on the duc de Duras (Emmanuel de Durfort) and was imprisoned in the Bastille (1780–82). On his release he went back to England, where he published *Mémoires sur la Bastille* (1783). Proceeding to Brussels, he obtained titles of nobility and 1,000 ducats from the Holy Roman emperor Joseph II; yet in 1789 he argued in favour of the Belgian insurgents against Joseph's regime.

At the beginning of the French Revolution, Linguet tried to win election as a deputy. Among the fiery and eloquent petitions that he subsequently presented was one to the constituent assembly in defense of the inhabitants of San Domingo against the "white tyrants" in 1791. He retired to Marnes, near Ville d'Avray, in 1792. Arrested there, he was eventually tried and condemned to death in Paris for having "flattered the despots of Vienna and London." He was guillotined in Paris on June 27, 1794.

Among his more important works are the following: *Théorie des lois civiles* (1767), an attack on Montesquieu; *Histoire impartiale des Jésuites* (1768); and *Histoire des révolutions de l'empire romain*, 2nd edition (1766–68).

LINGUISTIC GEOGRAPHY: see DIALECT GEOGRAPHY.

LINGUISTICS is the study of language (*q.v.*). It covers the structure of languages, their bearing on other human activities and on one another, and their history. The description of structures has come to involve methods like those of mathematics, especially in the fields of communication and information theory (*q.v.*). Language is a part of human behaviour, and linguistics therefore a social science; or, in some aspects, even a branch of anthropology. It is also linked with the humanities, because some of its source material comes from literature, art and history.

Divisions.—The field may be divided into pre-, micro- and metalinguistics. The first deals with the physical and biological aspects of language, the second with analysis of language systems (descriptive, comparative and general), the third with the links between language and culture as a whole, and thus with meaning. Finally, there is the history of languages, both of systems as such and of their social impact. The main divisions of this article are as follows:

- I. History of Linguistic Studies
- II. Descriptive Linguistics
 - A. Descriptive Phonology
 - B. Morphemic Analysis
 - C. Syntax
 - D. Linguistic Patterning
 - E. Meaning
 - F. Linguistic Change
- III. The External History of Language
 - A. Language as a Social Force
 - B. Common and Hybrid Languages
 - C. Formation of Dialects
 - D. Reciprocal Influence of Languages
 - E. Growing Time

I. HISTORY OF LINGUISTIC STUDIES

Beginnings.—Observations on language are often first made on sacred texts that have survived unchanged for long periods; thus may arise a body of grammar and a tradition of grammatical examination. The Vedas of India have been studied in this way, the extant compilation being attributed to Pāṇini (*c.* 400 B.C.), the first known precursor of modern linguistics. He expressed his findings on the original texts in quasi-mathematical symbols, a method that has remained exemplary in many respects.

Greek literature, too, provided a vast field for linguistic study. However, the Greeks had no sacred texts but were interested rather in studying the world around them by means of language. They developed a grammatical tradition which enabled them to give an adequate theoretical account of their language. This philosophical grammar passed to the Romans with some differences because of the peculiarities of Latin. The Greco-Roman tradition survived into medieval times, and after the Renaissance was applied to the modern languages of Europe. Since the latter were different in structure, the classical analysis did not fit, but was stretched to cover the differences.

With the discovery of the new world the linguistic experience of the western peoples widened, but grammatical tradition made it difficult to record and describe accurately the newly found languages. In the 17th century, however, Europeans became acquainted with the traditions of India and began to learn Sanskrit. In doing so they learned about the Indic grammatical school of Pāṇini and his followers. This led to a new view of languages and of grammatical description. As the principles of Pāṇini's descriptive techniques became known and as more new languages were found, the foundations of modern linguistic and logical analysis became firmer. However, they were not fully established until the end of the 19th century in European and American linguistic schools (*see below*). The discovery of Sanskrit brought about the rise of 19th-century comparative linguistics. The techniques thus developed were the first scientific linguistics in the western world.

Comparative Linguistics.—Among the 18th-century Englishmen in India who learned Sanskrit and began to study Indic literature was Sir William Jones. In 1786 he announced that the resemblance of Sanskrit to Greek and Latin was too close to be due to chance, and showed that all three "sprung from some common source which, perhaps, no longer exists," and that Germanic and Celtic probably had the same origin. This is not the first recorded recognition of what constitutes language relationship as understood by modern linguistics, but it may be counted as the beginning of comparative linguistics.

Little had been done to state resemblances systematically. Where it was apparent that a language like Italian was somehow a later form of Latin, it was considered a corruption of a perfect original. The thinking started by Jones led to the recognition that languages change constantly, that the changes are systematic and regular, and that by careful examination of the changes within a

language and comparison of the differences between languages, origins and relationships can be correctly established.

For the Indo-European languages, the beginning of systematic comparison was a treatise on verb inflection in Sanskrit, Greek, Latin, Persian and Germanic, published in 1816 by Franz Bopp. In 1818 Rasmus C. Rask and in 1819 Jacob Grimm examined the relationships of the Germanic languages to one another. In 1833–56 August Friedrich Pott published his etymological studies of Indo-European. August Schleicher, in 1861, published a comparative grammar of the Indo-European languages, and in 1886 Karl Brugmann and Berthold Delbrück began to publish their *Outline of the Comparative Grammar of the Indo-European Languages*, which remained the standard work of reference in the field. Friedrich C. Diez studied the Romance languages in a comparative grammar (1836–44), Johann Kaspar Zeuss began the study of Celtic (1853) and Franz von Miklosich wrote a comparative grammar of the Slavic languages (1852–74).

The interest in comparative linguistics led to the investigation of other language families (Finno-Ugric and Semitic at first), and also to the beginning of the descriptive treatment of contemporary languages as if they had no history. The comparative linguistics of the 19th century was the beginning of all modern linguistic science, and from it grew what is now called structural linguistics.

Philosophical and Scientific Approaches to Linguistics.—Although linguistics in the 19th century remained mainly a historical science, general linguistics was initiated by scholars with a philosophical interest in language. Foremost among them was the German Wilhelm von Humboldt (1767–1835). Especially through his introduction to the work *Über die Kawisprache auf der Insel Java* (1836–39), he has been regarded in Germany as the founder of general linguistics. He considers language in general as a spontaneous emanation of the spirit; the individual languages, however, have been developed by the different peoples and marked by their spiritual characteristics. Language is not a thing (*ergon*) but activity (*energia*). Humboldt characterizes a number of structurally very different languages: Semitic, Delaware, Chinese and Burmese. His philosophical and psychological point of view, however, is very different from that of modern linguists and his exposition and style are often obscure. Darwin, too, had a great influence among linguists, many of whom in the latter half of the 19th century regarded their subject as a natural science. Schleicher compared it to botany. The phonology of the earlier comparatists had not been very rigorous. In the 1870s and 1880s a group of German scholars, August Leskien (1840–1916), Karl Brugmann (1849–1919), Wilhelm Braune (1850–1926), Hermann Paul (1846–1921) and Hermann Osthoff (1847–1909), contended that linguistic development follows laws which are without exceptions but which operate only during a certain period of time. Apparent exceptions were said to be due to analogy; i.e., to be forms developed on the pattern of others of the same inflection or group of words which had replaced the “true,” “phonetic” form. Although some of the leading linguists, such as William Dwight Whitney (1827–94), Hugo Schuchardt (1842–1927) and, later, Otto Jespersen (1860–1943) and the so-called French school, did not partake in this theory, which has now been abandoned, it contributed very effectively to making the comparative method more rigorous. At the same time the instrumental study of phonetics led by J. P. Rousselot (1846–1924) had similar results. The French school, with its most prominent representatives M. Grammont (1866–1946), A. Meillet (1866–1936) and J. Vendryès (1875–1960), showed that the phonetic/phonemic changes belong to general types found in all languages. They stressed the importance of the linguistic system in which the change takes place. The Dutchman Jacobus van Ginneken (1877–1945) connected their views with the theory of the nature of psychological automatism propounded by Pierre Janet (1859–1947). Meillet, who was also a comparatist, published outstanding contributions to the Indo-European languages. He is also the founder of the sociology of language. He took his point of departure in Émile Durkheim’s definition of what is social, established that the definition fits language exactly and showed some of the consequences that the social character of language has for the understanding of linguistic change.

Toward the end of the 19th century and the beginning of the 20th, dialect studies received a great impetus. A new branch of linguistics, dialect geography (*q.v.*), got its precise methods particularly through the work of J. Gilliéron (1854–1926), whose dialect atlas of France became a model of other atlases in many countries.

Descriptive and Structural Linguistics.—The great interest in comparative linguistic studies in Europe did not include much descriptive work. As interests in comparative work spread to the lesser known languages, extensive descriptive studies became necessary to provide a base for reconstruction; likewise for the languages of Asia and the dialects of the standard languages of Europe.

Meanwhile, certain theoretical problems arose, such as the question of the relation of language to things talked about. This was met by a study of the meaning or content of linguistic forms, which soon required increasing attention to language as a systematic structure rather than as an aggregate of isolated forms. Ferdinand de Saussure (1857–1913), in his teaching at Geneva, developed a theory of linguistic structure. As a young man he had already exercised his structural bent by suggesting (in 1875) a theoretical approach to the phonological structure of Indo-European that differed markedly from the accepted doctrine as found in the work of Karl Brugmann and his predecessors. De Saussure postulated a relationship between the apparent short and long vowels of proto-Indo-European in which the short vowels were basic, and the long vowels were reconstructed as original sequences of a short vowel and a lengthening element which was described as some kind of *h*-like consonant. When Hittite was discovered in 1907 and later analyzed it was found that several such consonants had actually existed and that De Saussure’s structural extrapolation had been a correct reconstruction (made also independently by the Dane A. Möller). This gave a new theoretical basis to Indo-European studies.

In Russia, working with the structure of the Slavic languages, Jan Baudouin de Courtenay (1845–1929) in 1894 produced a study of their phonological structure in which the modern concepts of phonemes and morphophonemic relationships were set forth for the first time. His ideas influenced various Russian and other European scholars and gave rise under the leadership of Nikolai Trubetskoi (of Vienna; 1890–1938) and Roman Jakobson to the so-called Prague school of phonology. The new theories of Trubetskoi and his colleagues first became known at the First International Congress of Linguists at The Hague in 1928; they formulated their principles at a congress of Slavic scholars in Prague in 1929. The results were published in the first volume of the series *Travaux du Cercle Linguistique de Prague*. This set of principles was the start of modern phonemic analysis.

De Saussure’s and Baudouin de Courtenay’s theoretical approaches have also guided the work of other European linguists. These came to be known as structuralist studies, though much of the comparative work of the 19th century and most of the anthropological linguistic work has also explicitly dealt with systematic structure.

Meanwhile linguistics in the United States had developed methods of description which have proved to be of great importance, for the Amerindian languages furnish highly interesting and important material. As early as the 17th century Roger Williams in Rhode Island was describing an Algonkian language under the title of “the language of America.” When the American Philological society was founded under the leadership of Benjamin Franklin, some of its members, Thomas Jefferson among them, showed much interest in American Indian languages and their description. As the frontier moved westward, white settlers met with many hitherto little known Indian tribes whose movements and habits became of vital concern to the U.S. government. Various agencies were established to deal with these matters, and some of the persons engaged in the work became interested in the languages of the Indians. Thus began a tradition of American Indian linguistics.

In 1842 the American Ethnological society was founded; one of its principal aims was the study of American Indian languages. About 30 years later the Bureau of American Ethnology was

started, as a part of the Smithsonian institution. The first director of the bureau, J. W. Powell, made it his principal interest to describe or at least identify the various languages of the Indians. In 1891 there was published, in the seventh annual report of the bureau for 1885-86, Powell's "Linguistic Families of North America" (pp. 1-142). This work used the already established principles of comparative linguistics to make preliminary classifications of the languages of the Indians of the United States and Canada. European scholars also became interested, and approximately 55 families were established so soundly that no serious error has been found since, though some of the families have been combined into larger groups. The result of this work, however, was not to lead to immediate further comparative work but to spur on the study of the individual languages.

In 1896 Franz Boas (1858-1942) began to teach anthropology at Columbia university. Originally trained as a natural scientist, he was led to approach linguistic study as a matter of description and not history. All his anthropological researches are accompanied by extensive study of the languages of the people observed.

While Boas was founding and fostering American anthropology and anthropological linguistics, work was also being done in the United States in the more traditional fields of Indo-European comparative linguistics. William Dwight Whitney, professor of Sanskrit at Yale, wrote a Sanskrit grammar that was, in effect, a modern version of Pāṇini's, without the esoteric symbolism. Whitney also wrote books on general linguistics.

The students of Whitney and Boas and their associates were thus all imbued with an interest in language description and structure. The most noted of these was Edward Sapir (1884-1939), Boas' most brilliant student, who became the leading theorist in the field of American Indian languages. In 1916 he published a paper suggesting the relationship of historical linguistic information to anthropological time perspective. In 1921 he published *Language*, a general work in linguistic science; in 1925 he produced a study that was a forerunner of modern phonemics, and in the last years of his life, as professor of linguistics and anthropology at Yale, contributed much to the development of Indo-European comparative studies.

Leonard Bloomfield (1887-1949) began his career as a traditional comparativist linguist, in Germanic studies. He soon began to take an interest in American Indian languages. In 1914 he published a general work on linguistics, and in 1933 wrote it into a new work entitled *Language*, still valuable as a text.

The kind of linguistic work done by the Americanists is comparatively rare in other parts of the world. In African languages there are linguistic studies with theoretical approaches similar in many respects, and some work of the same kind was done in India, the far east, and with the languages of the Pacific area.

Linguistics is gaining recognition as an autonomous science in an increasing number of universities. More languages are being studied from the comparative point of view in the hope of allotting them to families. The discovery, mainly on cuneiform tablets, of further extinct languages in the near east has been of great help to Indo-European and Semitic linguistic history. The discovery of Hittite, especially, has compelled modification of the theory of the Indo-European parent language. The decipherment by Michael Ventris (1922-56) of the Greek of the Aegean period promised rich results in the 1960s. Similarly important for the Semitic languages was the discovery of Ugaritic, a west Semitic language in a cuneiform alphabet on tablets found at Ras Shamra. Descriptive studies of languages and surveys of languages and dialects were being published not only in countries of European culture but also in Japan and China.

(G. L. T.; A. A. S.)

II. DESCRIPTIVE LINGUISTICS

This is the analysis of the elements that make up the system of

signs we call a language. An utterance is split into a sequence of segments that are either phonemes (units of sound) or morphemes (units of structure or signs).

A. DESCRIPTIVE PHONOLOGY

The utterances of individual speakers are made up of sound patterns produced by the organs of speech. These patterns must conform to the linguistic system, which has a social existence and is the vehicle for communication between members of a group. Phonetics deals with the physiological aspects of speech; it studies sounds and articulations. Phonemics studies the phonemes of a language; a phoneme, as such, has no meaning, but serves to distinguish morphemes from each other.

Phonetics.—Speech sounds may be classified into vowels and consonants. Vowels are produced in the oral passage, with or without the help of the nasal passage. The former functions like a resonance chamber, allowing the freely and regularly vibrating air to pass almost unhindered from the throat. Consonants arise when there are various obstacles, formed by tongue, teeth, palate and lips, introducing noise (irregular vibrations) into the sound. Vowels and consonants may be voiced (when the vocal cords vibrate) or voiceless.

Articulation is governed by tongue height, tongue advancement or retraction, and lip spreading or rounding (see Table I).

TABLE I.—Table Used in Classifying Vowels

	Front		Central		Back	
	Unrounded	Rounded	Unrounded	Rounded	Unrounded	Rounded
High . . .						
Lower high						
Higher mid						
Mid . . .						
Lower mid						
Higher low						
Low . . .						

A set of symbols representing the various sounds is called a phonetic alphabet. If defined as, *e.g.*, in Table I, the set may lead to predictions. Before 1950, the vowel sounds in the higher low and low front rounded positions had never been encountered in any language, though any phonetician could make them; then a Mongolian dialect was found which did have them, and they were easily identified when heard.

The following are some examples, using the initials of the rows and columns of Table I: HFU like French *i* in *si*; LhFU like English *i* in *hit*; HmFU like French *é* in *café*; MFU like English *e* in *met*; LmFU like French *e* in *nette*; HlFU like English *a* in *hat*; LFU like French *a* in *patte*; HFR like French *u* in *tu*; MCU like English *a* in *sofa*; LBU like American English *o* in *hot*; HBR like southern standard English *o* in *hot*. Sounds slightly different from the standard are described by modifying terms and denoted by symbols with added diacritics. Thus Spanish *i* in *si* is lower and less tense than French *i* in *si*; if the symbol [i̞] is used for the French sound, the Spanish one can be denoted by [i̞̞], where ̞̞ means lower, and ̞ means relaxed. It is customary to put phonetic symbols in brackets.

Consonants are classified in a table showing place of articulation and manner of articulation as in Table II.

Bilabials are made with the two lips, as *p* in *pit*, *b* in *bid* (voiceless and voiced bilabial stops respectively), *m* in *mid* (voiced

TABLE II.—*Consonant Table Showing Place and Manner of Articulation.*

[illegible]

nasal). Labiodentals are the *f* and *v* sounds (voiceless and voiced spirants). Apical sounds are made by the tip of the tongue against the teeth (dental—as *th* in *thin*, a voiceless spirant), against the upper gums back of the teeth (alveolar—as English *t* in *tin*, a voiceless stop), or slightly raised or curled back of the gums (cacuminal—as American English *t* after *r* as in *hurt*, a voiceless stop). Frontals or palatals are made by the middle portion of the tongue (the “front” technically) against the roof of the mouth: English *sh* in *shoe* is for most speakers a midpalatal voiceless spirant. Dorsals are made by the back of the tongue against the roof of the mouth: English *c* in *car* represents the midvelar voiceless stop. A glottal spirant is English *h* in *hot*. Stops are made by closing the passage and then releasing it. Nasals are stops with accompanying opening of the nasal passage. Spirants are sounds made by approaching the articulating organs but leaving part of the passage open. Laterals are made by leaving a passage open at one or both sides of the articulator (as *l* in English *low*). Vibrants are made by rapidly striking the articulating organs together; the sound represented by *brrr*, indicative of cold, is usually a bilabial voiced vibrant; the heavily trilled *r* of Spanish *rey* is an alveolar voiced vibrant; some speakers of Parisian French use a postvelar voiced vibrant for *r* in *rouge*. Some or all consonants of a language may oppose palatal and nonpalatal types; in other languages a certain number of consonants may be combined with a glottal stop. All languages use the same general types of sound, differing in minor details; for example, the voiceless English stops *p*, *t*, *k* are followed by a voiceless breath, the corresponding French sounds are not. As with vowels, there are symbols for all the sounds in the table and various other symbols and modifiers which are not shown in it.

In addition to vowels and consonants, various other sound phenomena can be recorded, such as pitch (high, mid, low, falling, rising, etc.), stress (loud, medial, soft, etc.), quantity (short, long, extra-long, etc.) and various kinds of voice qualities and other modifications (nasal twang, whisper, etc.); on these there is less agreement than on vowel and consonant analysis. (See *PRONOUNTICS*.)

Phonemics.—In every language the number of different sounds is quite large; the number of significant differences is smaller. For instance, in English the word *pit* begins with a voiceless bilabial fortis (tense) stop, with aspirated release; in *spit* the *p* represents a voiceless bilabial lenis (lax) stop, with smooth release into the vowel; in *upper* the internal consonant sound is a voiceless bilabial fortis stop with smooth release; in *up* the final consonant is usually a voiceless bilabial fortis stop without release. The phonetically untrained speaker of the language is unaware of these details, and to him these are all the “same” sound. On the other hand the difference between the voiceless bilabial sounds in *pit*, *ripping*, *rip* and the voiced bilabial lenis stop in *bit*, *ribbing*, *rib* is heard and noted by the speaker of English. In the latter case he does not note, however, that *b* in *bit* begins without voice, *b* in *ribbing* is fully voiced and *b* in *rib* ends voiceless.

The various *p* sounds discussed are the members of a class of sounds which, as a whole, is in significant contrast with other such classes. Such a class of sounds is called a phoneme. It is the smallest unit of sound. It is customary to represent phonemes by symbols chosen from among those used for the various members of the class, and to enclose them in slant lines; i.e., the phoneme /p/, the phoneme /b/, etc. The members of a phoneme are called its allophones. The allophones of a phoneme form a complementary distribution: each occurs in statable positions, and no two occur in the same positions. Thus aspirated *p* is an initial allophone of /p/; lenis *p* is the allophone after *s*; fortis with smooth release is the allophone between vowels if the following vowel is weak; unreleased is the allophone in final position. Another criterion for phoneme membership is phonetic similarity: all the allophones of English /p/ are voiceless bilabial stops. But the /b/ allophones are also bilabial stops, so that mere phonetic similarity is not decisive.

The extent of the phonemic unit is found by substituting contrasting elements of utterances, and especially by comparing minimal pairs (elements that are partly identical). English *bit*,

pit, *sit* show that *b*, *p* and *s* are separate phonemes. Some linguists distinguish between phonemes (or sound types) and phones, the latter being the elements found by substitution. English *tattoo* contains four phones /t + æ + t + u/ but only three phonemes /t/, /æ/ and /u/.

The phonemes may be analyzed into their inherent features. These, like the prosodic features (see below), belong to pairs of opposed qualities in the two series of sonority and tonality. Examples of sonority are the opposition between vocalic and non-vocalic phonemes found in all languages, of voiced versus voiceless (e.g., English *b*, *d*, *g* versus *p*, *t*, *k*); examples of tonality are the opposition between grave and acute, between velar and labial, palatal and dental. Russian and many other languages systematically oppose palatal and nonpalatal consonants. Some oppositions are found only in certain parts of the world; e.g., the contrast between glottalized and nonglottalized consonants is especially frequent in the Caucasian and Amerindian languages.

Languages also make use of other elements which characterize syllables, words, phrases or sentences. These elements are called prosodic or supersegmental. For example, pitch may be used to distinguish between a question and a statement; it may also be used to oppose words or forms. Swedish and Norwegian have two lexical tones; e.g., Norwegian *bryter* “(he) breaks” has a falling tone, while *bryter* “(a) wrestler” has a rising-falling tone. The ancient Greek tone was distinctive (e.g., *tomós* “cutting,” “sharp,” *tómos* “slice”), but it could not be further back from the end of the word than on the third last syllable if the final vowel was short; or than on the penultimate syllable if the final vowel was long. The Latin tone was mechanically placed on the penultimate syllable if this was long; on the third last if the penultimate was short. Some languages use difference in length between the syllable crests as a distinctive trait. Latin distinguished between *lātus* “broad,” “wide” and *lātus* “side.” When a language has both stress and quantity, the quantity is usually subordinate to stress. In Norwegian and Swedish a long vowel is usually found only in a stressed open syllable. In a stressed closed syllable and in all unstressed syllables the vowel is short (e.g., Nor. *bāke* “to bake”; *bāske* “to struggle”), except where other forms keep it long (e.g., *spist*, past participle of *spise* “to eat”).

Many languages use stress, giving certain syllables of the utterance a stronger stress than others. The stress may be merely phonetic and lie on the same syllable of each word, as, e.g., in Finnish or Czech, where it lies on the first syllable and merely serves to indicate where a new word begins; or it may serve to distinguish between different words or different forms, as in Russian, where *zamók* means “a lock,” but *zámok* “a castle.”

The spoken phonemes of the utterance are grouped into rhythmic units which are called syllables. A syllable has a peak where it is most sonorous, usually a vowel or a diphthong; but the peak may also be a consonant—most frequently a liquid, a nasal or a vibrant (e.g., in Serbo-Croatian, *srpski* “Serbian”). The syllable may consist of only a vowel or of the sonorous part preceded and followed by one or more consonants. The physiological basis of the syllable seems to be a puff of air forced upward through the vocal channel by compression of the intercostal muscles. Thus the syllable consists of release, culmination and arrest of the pulse. The point where the arrest of the pulse falls in the spoken chain varies in the different languages; as a rule it is of no semantic significance. In some languages, such as classical Latin and Greek, the different types of verse forms depend on the number and character of the syllables.

To understand an utterance it is necessary to grasp not only its different elements (vowels, consonants, etc.) but also the boundaries inside the spoken chain. This falls into rhythmic groups characterized by intonation and stress, and scanned by pauses. The transition from the pause to the first phoneme of the utterance and from the last phoneme to the pause is called juncture or open juncture; the ordinary passage inside the chain is often called close juncture. Inside the chain, however, there may be open juncture where there are morphological boundaries, as can be seen in the difference between Eng. *night rate* and *nitrate*; a *name*, but *an aim*. French has close juncture in such

cases; there is no difference between the elements of the group and the word as far as junctures are concerned. By using the methods sketched above with additional refinement of detail, all the sounds of a language may be grouped into a limited number of phonemes. Some languages, such as, for example, the Oceanic, have a relatively small number of phonemes, others as many as 50 or more. The greatest number known is 78 consonants and 2 (or 3) vowels, found in a Northwest Caucasian dialect spoken by Ubykhs in Turkey.

B. MORPHEMIC ANALYSIS

An utterance falls into syllables with boundaries called junctures. From the point of view of function and meaning it is composed of unities called morphemes. They are its smallest individually meaningful elements and may either refer to something outside language, containing what is called a lexical meaning, or may be an element of formation and have a special function inside the utterance. In European linguistics the former type are often called *semantemes* (in the U.S. sometimes *lexemes*); the latter, *morphemes*. Americans use "morpheme" in both senses. The morphemes may be simple or complex. They may contain bound forms (also called grammatical morphemes) which are never used alone, as, for example, *-ish* in English *boyish*, *reddish*, or *-s* in *boys*, *girls*. There may also be free forms which can be used alone in the utterance. A minimum free form is a word. Words can be divided into word classes or parts of speech. In traditional grammar books the parts of speech are usually defined semantically, but such definitions are not consistent. Thus, a noun is usually defined as a part of speech that denotes a person (or an animal) or a thing. In an example like *buy this car*, the form *buy* is a verb, whereas in *this car is a good buy* it is a noun; and in both cases it designates an action. The main parts of speech must be defined syntactically, through their forms and distribution. A verb and a noun do not appear in the same surroundings in the utterance.

A morpheme may have different phonemic forms according to the environment in which it occurs. Such different forms are called *allomorphs* or *morphemic variants*. Some linguists use the term *morph* to designate each different representative of a morpheme and call *allomorphs* all the different morphs that represent a given morpheme. The morphs *sell* and *sold* are allomorphs, since they are phonemically different and are used in different environments.

Morphophonemics.—The study of the phonemic structure of the morpheme is called *morphophonemics*. A detailed examination of such structures demands a thorough knowledge of a language and of its phonetic and phonemic character. This study is still in its beginnings. If a language is known only in some conventional written form, important elements of its morphophonemic structure may be unknown. An important morphophonological trait in many languages is the change within the morpheme of phonemes that express a grammatical relation, accompanied or not by additional elements. Examples are English *bind:bound*, *knife:knives*; Russian *son* "dream": genitive *sna* (change from *o* to nothing); Irish *bád* "boat": genitive *báid* (change from *d* to palatal *d*; the *i* is a nonphonemic glide).

English words may begin with a vowel; of the nine simple vowels five are common as initials—those in *it*, *elder*, *at*, *up*, *otter*; in weak-stressed syllables, a sixth vowel occurs frequently, that used in *event* and other words by people who also use the *up* vowel in *above*, *allow*. The vowel of *put* occurs initially for some speakers only in the exclamation *oops* (others use here the vowel-plus-semivowel of *food*). In *obey* and other words spelled with *o* there may be instances of the short vowel also found in New England *coat*; in *already* as pronounced by some, the ninth vowel is found. English words may also begin with one of the vowel-plus-semivowel combinations, varying according to geographical region. An English word may begin with any of the single consonants except the *ng* of *sing*. Also found initially are groups of two or three consonants; the two-consonant clusters are numerous but limited to certain kinds: *tr-* exists but not *tl-*, while both *pr-* and *pl-* are found; there are only a few three-consonant clusters:

*spl-, spr-, str-, /skl/ spelled scl-, /skr/ spelled scr-, /skw/ spelled squ-, /spy/ in words spelled sp- before u or eu or ew, /sty/ in words spelled st- before u or eu or ew (but many speakers of English do not use the /y/ in these words). English words may end in a weak-stressed short vowel, or in a vowel-semivowel combination with any stress, or in any single consonant, and in clusters of two or, more rarely, three or four consonants. Every English word has at least one vowel and, when said by itself, has one (and only one) primary stress. English words may be of one syllable (i.e., with one vowel) or of many syllables, though most are of one, two or three syllables. Various stress patterns are noted in English words: *upper, above, animal, allowing, entertain*, etc. All English utterances, whether long or short, are said with a sequence of pitches of some kind, the most usual (declarative sentence) being 2-3-1, the 3 falling on the syllable with the primary stress.*

There are also many instances of addition of one or two (or occasionally more) sounds to a word to form related words: *cat, cats; bed, beds; rose, roses; go, going; nice, niceness; starve, starvation*. In some cases there are notable changes in the original form: *knife, knives; take, took; vain, vanity*.

A complete morphophonemic analysis has not been made for any language. English has inflectional morphemes, derivational morphemes and base morphemes. The first two are suffixes; they come after the base, inflectional suffixes being last. There are also supersegmental phonemes and morphemes. These are the patterns of stress (with or without one or more internal junctures). Thus *boy, boys, boyish, boyishness, boyishnesses* are analyzed morphemically as follows: base *boy-*; inflectional suffix *-s* (pronounced /z/); derivational suffixes *-ish* and *-ness*; inflectional suffix *-es* (pronounced /ɪz/, *i* being the high midvowel of the first syllable of *event*); supersegmental "primary stress" on *boy* and *boys*, "primary-weak" on *boyish*, "primary-weak-weak" on *boyishness*, "primary-weak-weak-weak" on *boyishnesses*. English also has some morphemes like *pre-, in-, a-, be-, re-*, that precede the base; these function like special kinds of bases, and are best labeled prebases.

In some languages there are genuine prefixes that function like suffixes in inflection or derivation. Classical Arabic has forms like *katabat* "she wrote," with *-t* for feminine third person subject; but *taktuba* "she is writing," where the prefix *t-* is the sign of the feminine. In the language of Taos Pueblo, New Mexico, most subject and object relations of verbs and the indications of possession for nouns are shown by prefixes: *tik'olq* "I ate it," where *ti-* means first person subject and third person singular object of one of five classes; *kikana* "our mother," where *ki-* means "our" (we being more than two). Some languages also have infix morphemes. Latin *relinquo* as compared with *relictus* shows an old *-n-* infix that functioned freely in Indo-European. Another kind of morpheme may be called the pattern morpheme: in Arabic *kataba* the base (or "root") is *k-t-b* "to write," and the pattern *-a-a-a* indicates suffix tense (perfect); in *taktuba* there is the same base, but the pattern is *-u-u-a*, indicating the prefix-infix-suffix tense (imperfect).

The inflectional morphemes of a language occur in paradigm sets. The paradigms are the basis for determining the kinds of words ("parts of speech") a language has. English has paradigms like the following: *boy, boy's, boys, boys'; man, man's, men, men's*; these establish the class of nouns, which are then defined as words that have inflection for plural and for possessive (or for one of these). The paradigms *go, goes, going, went, gone; talk, talks, talking, talked*, etc., establish the word class of verbs, defined as words inflected for past and, in most cases, also for gender indicated subject in the nonpast (*he, she, it talks*), present participle and past participle. English also has the personal pronouns *I, you* (and *thou*), *we, he, she, it, they, who*, with an irregular inflectional pattern (*I, me, my, mine*, etc.). All other English words are uninflected (including adjectives with derived comparative and superlative), and their further classification as adverbs, prepositions, etc., is made by syntactic criteria (see below).

These definitions may be supplemented by criteria of distribution. In English, adjectives, for example, can only appear in certain places in the utterance. Each language has its own pattern and its own set of parts of speech specially to be defined. For

spoken French, adjectives are defined as words that may be inflected both in gender (e.g., *bon* "good," fem. *bonne*), in number (sing., *égal* "equal," pl. *égaux* [fem. pl. *égales*]), and as words placed behind the noun. But there are exceptions to this rule. The adjective *bon* /bo/ is pronounced the same in the plural (but written *bons*); the feminine form *bonne* /bon/ is likewise pronounced the same in the plural (written *bonnes*). An adjective such as *brave* is pronounced the same in all forms (but written *braves* in the plural). Certain adjectives may sometimes be placed before the noun and this may entail a change of meaning: e.g., *un personnage sacré* "a holy person"; but *un sacré personnage* "a damned person," in the metaphorical sense.

Although the parts of speech used in languages of the same origin or belonging to the same cultural area are very similar, none occurs everywhere. It was an error of earlier linguists to believe that the classical Latin-Greek system was universal. As an example of the differences there is the Amerindian language Nootka, which shows a contrast between inflected and uninflected forms very different from that between nouns and verbs in European languages. Without any overt inflectional affix, stems like [*waka* 'k-] "go"; [*qo* 'ʔ as-] "man," "person"; [*ʔ i* 'h-] "large"; and [*ʔ athija*-] "at night" are used syntactically in a way that corresponds to "a going," "a trip"; "a man," "a person"; "a large thing"; "the night time" (ʔ is the symbol of the glottal stop; *h* designates a pharyngeal spirant, ' indicates length). With the inflectional affix *-ma*, which denotes an implicit third person singular subject, the words can be translated "he goes"; "he is a man"; "he is large"; "he does it at night." The words of a language without inflections can be classified only by distribution; i.e., by syntactical means.

C. SYNTAX

A description of a linguistic structure must not only delimit its phonemes and morphemes but also determine how the units called words and their forms are construed within the utterance. Traditional grammar distinguishes between study of grammatical forms as such, which is called morphology, and study of their use and of their order within the utterance. Some linguists prefer another division extending morphology to the use of the grammatical forms and establishing a special division for the word order within the utterance.

Phrases and Sentences.—Syntax deals with the grouping of the free forms into phrases and the arrangement of the phrases into simple or complex sentences, the maximum forms in an utterance. Exclamations such as *Come! Down!* are called minor sentences, whereas full sentences consist of two main parts, one usually called subject and the other predicate. In the commonest type of English sentence the relation between these two is that of actor (the subject) and action (the predicate). In older Indo-European languages there was also another kind, in which the first component (corresponding to the subject-actor of the English type) was a substantive and the second component (equated to the first) might be a substantive, an adjective or an adverb. This usage still exists in Russian: e.g., *Ivan durak* "Ivan is a fool"; *otets doma* "father is at home." This variety is also called a nominal sentence. A variant of the subject-predicate type is found in certain languages such as Latin, which opposes an actor-action construction *amat* "he (she, it) loves," to a goal-action construction *amatur* "he (she, it) is loved" (an opposition which in traditional grammar is called active-passive).

A full sentence need not be bipartite. In German there are so-called impersonal sentences such as *mir ist kalt* "to me is cold" (i.e., "I feel cold"); or *hier wird geraucht* "here it is smoked" (i.e., "people smoke here").

The sentence contains different syntactic constructions. Two or more free forms may be combined in a resultant phrase. This may be exocentric, as when it belongs to a form-class other than that of any of the members. *John ran*, for example, is neither a noun-expression like *John* nor a finite verb like *ran*. Another kind of exocentric construction is the combination of a preposition and its complements; yet another is the subordinate clause containing an element expressing subordination (e.g., *when Charles*

married). Other constructions, called endocentric, are either co-ordinating (as in *boys and girls*), where the members belong to the same form-class (the co-ordinator *and* may be absent); or attributive or subordinate, where the resultant phrase belongs to the same form-class as one of the constituents (called the head, the primary or the centre). *Poor John* belongs to the same form-class as the head *John*; *poor* is the attribute. The latter may be a subordinate phrase, e.g., *very fresh milk*, where *fresh* is in the same relation to *very* as *milk* is to *very fresh*.

In inflected languages the form of one member of an exocentric construction may be determined or "governed" by the other. In German the object of a verb may be in the accusative case: *einen Brief schreiben* "to write a letter"; in the dative: *einem auf der Strasse begegnen* "to meet someone in the street"; or in the genitive: *sich eines Dinges erinnern* "to remember a thing." In such languages the members of an endocentric as well as of an exocentric phrase may be subject to rules of number. In many Indo-European languages the verb is dependent upon the subject for number, and the attributive on the member it qualifies.

Word Order.—There are in all languages rules of word order for both endocentric and exocentric constructions. In the attributive endocentric construction, the attribute precedes the head in English but follows (with certain exceptions) in French: *fresh butter*; but *du beurre frais*. In the attribute, however, French has the same word order as in English: *very fresh butter*: *du beurre très frais*. In Irish the verb comes first in the sentence, in German last in the subordinate clause. In highly inflected languages the word order is free and may be used to throw into relief a member of the sentence: Latin *Aulus puellam amat*; *puellam Aulus amat*; *amat Aulus puellam* all mean "Aulus loves the girl." In the first case "Aulus," in the second "the girl" and in the third "loves" are emphasized. Syntactic constructions and sentences are accompanied by special prosodic elements such as intonation and stress. Intonation may distinguish a statement from a question. In English the members of an attributive endocentric construction are both equally stressed: *the first prize*; in French the group has final stress: *une jeune fille*; *un homme bon*.

D. LINGUISTIC PATTERNING

Phonemic Systems.—The phonemic systems vary from language to language; their variations are, however, limited by the speech organs, which are practically the same in all men. In all languages the phonemes are arranged into structures with contrasting series. In the vocalic systems of most languages, use is made of sonority and tonality—contrasting *a* with *i* and *u*, for example. The series of vowels contrasting in tonality are usually, above the lowest level (the *a* level), composed of the same number of phonemes, so that a language which contrasts *i* and *u* and has an *e* will also have an *o*. The vowels above the *a* level of the dark (or back) series are usually rounded. At the lowest level some languages have only one *a*, others contrast two types. Languages may also have one or (less often) more than one intermediate series, the members of which are not more numerous than those of the two contrasting series. French, for example, has the following system (of nonnasal vowels):

<i>i</i>	<i>ü</i>	<i>u</i>	
<i>e</i>	<i>oe</i>	<i>ø</i>	(closed)
<i>ɛ</i>	<i>œ</i>	<i>ɶ</i>	(open)
<i>a</i>		<i>ɑ</i>	

Few languages have systems in which there is only contrast in sonority between the vowels. An example, however, is Adyge in the Caucasus, which has three vowels contrasting only in sonority: one closed, transcribed *ə*; one half open, *e*; and one open, *a*. These vowels have a series of allophones; the *ə* has the phonetic form *i* after a palatal and *u* after a rounded guttural, etc. Vowels are often pronounced with a nasal twang which has no phonemic relevance, but a certain number of languages have nasalized vowels as phonemes. In French there is a system of such vowels which

corresponds to the open types of the nonnasal vowels:

ē ē̄ ē̄̄
ē̄̄̄

(as in *fin, un, on, dans*).

In some languages the vowels of the different syllables are dependent on one another, a phenomenon usually called vowel harmony. In Ibo (west Africa) all vowels of the word must be either closed or open. In Turkish the vowel of the ending is grave or acute according to the vowel of the radical; e.g., *peder-ler* "fathers" from *peder*; but *atlar* "horses" from *at*.

The consonant systems show as a rule more complicated contrasts. Most languages oppose dentals, labials and gutturals and have an *s* (the latter is absent from some languages, e.g., the Australian languages, except those of Cape York; and from eastern Nuba). Some languages, especially in America, have laterals; others, series of laryngeals. In Bushman, Hottentot, Zulu and Sandawe in south Africa, clicks are used.

Some languages contrast voiced and voiceless types in the stops, often also in the spirants, less often in the liquids and vibrants; others do not distinguish *d, b, g* from *t, p, k*. Certain languages, such as Russian or Modern Irish, have a palatal series opposed to a neutral or more or less velarized series. Certain languages, for example in the Caucasus and in America, have series of consonants accompanied by a glottal stop in contrast with ordinary consonants. Some contrast weak and short consonants with intense and long ones. In the archaic dialects of Modern Irish, for example, [*gan*] "without" is distinguished from [*gaN*] (written *ganm*) "scarce"; [*mə'ləbi*] "my bed" from [*ə L'abi*] "her bed" (written *mo leabaidh* and *a leabaidh*; *l'* and *L'* are palatal consonants).

Efik in west Africa distinguishes the aorist from the subjunctive by tonal differences (' before the syllable indicates a high tone, . a low). The roots, which function as imperatives, of the verbs meaning "to think," "to put" and "to run" have different tones, viz. *'ke're* "think"; *'do'ri* "put"; *'fe'he* "run." In the aorist they keep these tones; *N'ke're* (*N* is a prefix, indicating the first person singular, which is phonetically assimilated to a following consonant); *N'do'ri*, *N'fe'he*; but in the subjunctive the final syllable is always low *N'ke.re*, *N'do.ri*, *N'fe.he*.

Grammatical Systems.—The grammatical structures of the languages of the world differ widely. It has been customary to distinguish "analytic" or "isolating" languages, which do not use inflections but always identify the word with the radical element (having no bound forms); "synthetic" languages, which have inflections combining the radical element of the word with a certain number of bound forms indicating its grammatical function in the sentence; and, finally, "polysynthetic" languages, which unite long strings of bound forms into single words corresponding to a number of different forms in the synthetic languages. Examples usually quoted are Chinese, an isolating language; Latin or Greek as synthetic languages; and a number of American Indian languages representing the polysynthetic type. Among the synthetic languages, agglutinative and fusional languages are distinguished. In the former, affixes are juxtaposed in such a way that they stand out clearly from one another, whereas in the latter they are more or less completely run together with the radical. A typical example of an agglutinative language is Turkish, with *peder* "father"; *peder-im* "my father"; *peder-ler* "fathers"; *peder-ler-i* "their fathers." In the older Indo-European languages fusion is more or less pronounced, as in such examples as Latin *pater* "father" (accusative *patrem*, genitive pl. *patrum*); *iecur* "liver" (gen. *iecinoris*); Sanskrit *yákr̥t* "liver" (gen. *yákr̥nas*).

Special grammatical categories occur. In the noun many languages contrast animate and inanimate forms by morphemes referring to living beings or to lifeless objects respectively. Some Indo-European languages also distinguish gender: masculine, feminine and neuter. Number also is expressed, in noun, verb and pronoun; more usually as singular versus plural. Dual, however, is also found; e.g., in Slovenian. Some languages have four categories: singular, dual, trial (triple) and plural; or singular, dual, paucal (few) and multiple (numerous).

Differences in time are important in the verbal systems especially of western European languages (e.g., the English contrast between *run* and *ran*), but in most languages the contrast is not between forms expressing time but between forms denoting aspect, i.e., the development of the action—its instantaneousness or duration; its intensity; its approach to a goal, etc. Aspect was also the dominating category in the older Indo-European languages (expressed in Greek by the present, the aorist and the perfect); it is partially expressed in modern western European languages. The French imperfect, for example, has aspect meaning; aspects in English are formed by tenses of the verb *to be* combined with a present participle. (See also GRAMMAR.)

Glossematic Analysis.—This type of analysis, first practised by Louis Hjelmslev, proceeds by gradual subdivision of a text until a complete and consistent description has been given; this requires more than attending to only one aspect of the text, e.g., phonology; linguistic form is important too. The substance of a language is regarded as variable and as manifesting itself as utterance, as written text or in other ways. The method uses new technical terms. On the whole it has not met with the approval of most other linguists, despite its original points of view.

E. MEANING

The definitions of the term "meaning" in linguistics are varied and controversial. According to the traditional point of view a word stands for something, refers to something, which is called its meaning or signification. F. de Saussure regards the linguistic sign as a combination of a concept and an acoustic image, the *signifié* "that which is signified," and *signifiant* "that which signifies." The relation, however, is not between the word and the *signifié* or "thing meant" (also called the "referent") but between what has been called the "name" or the "expression" (i.e., the morpheme) and the sense or "content" (also called the "reference"). An often-used example will show this. The words for colours in different languages often do not correspond but omit parts of the spectrum. Welsh "green" is *gwyrd* or *glas*; "blue" is *glas*; "gray" is *glas* or *llwyd*; "brown" is *llwyd*. Thus the parts of the spectrum have different limits in Welsh and in English; the line dividing "green" from "blue" in English is not found in Welsh. The pattern may be shown thus:

green	blue	gray	brown
<i>gwyrd</i>	<i>glas</i>	<i>llwyd</i>	

The relationship of expression, content and "thing meant" enables any one of them to evoke one or both of the others.

It is customary to distinguish lexical meaning from grammatical meaning and referential meaning from distributional meaning. This last is the element of meaning which opposes one member of a paradigm to another or which is implied in the distribution of the morphemes of a sentence. Grammatical meaning may be the same, though it is differently expressed. In Latin *puer puellam amat* and in English *the boy loves the girl* the grammatical meaning is the same; but it is expressed in Latin through the accusative of *puella* and in English by the position of *the girl* after the verb.

Referential or lexical meaning may be very complex. According to the *Shorter Oxford Dictionary* the verb *reason* has the following actual meanings: (1) to employ reasoning or argument (with a person) in order to influence his conduct or opinions; (2) to think in a connected, sensible or logical manner; to employ the faculty of reason in forming conclusions; (3) (with object clause): to explain, support, infer, deal with by (or as by) reasoning; (4) to bring (a person) into, out of a state of mind by reasoning; (5) to put (down by reasoning); and (6) to think (out), to arrange the thought of in a logical manner. Cases with many more different meanings could be quoted.

One might expect the lexical meanings of a word to form a system, but no convincing method of exhibiting this has yet been found.

Adherents of behaviourist methods in linguistics see meaning as something outside the proper structure of language, the study of it belonging to what is called metalinguistics. L. Bloomfield, who introduced these methods, describes meaning in terms of

stimulus and reaction. An extralinguistic stimulus (S) prompts the speaker to a linguistic reaction (r) which, reaching the listener as a linguistic stimulus (s), elicits an extralinguistic reaction (R) on his part, thus:

S — r s — R

It has even been attempted, by Zellig S. Harris, to describe language without reference to meaning. The attempt was not a success, but it has shown that a description of a language must start with the form and distribution of morphemes. See also SEMANTICS IN LINGUISTICS.

F. LINGUISTIC CHANGE

No language is stable, though the rate of change varies widely; and not all linguistic elements are equally exposed to change. Most exposed is the vocabulary, especially in languages of rapidly evolving societies. Vocabulary changes may not affect the structure of a language or only slightly so. The changes that usually have the greatest effect in linguistic development are those in phonetic-phonemic structure.

Speech is realized through a network of movements of the speech organs which are directed from the brain. These movements are extremely short, being measured in hundredths of seconds. The delicate equilibrium of articulation of the sounds that produce the phonemes of a language is therefore easily upset. One part of an articulation may come too early or last too long; articulations may be shortened or slurred over under the influence of coming articulations or at the end of an utterance before pause. Changes then follow. They belong to categories or types of which the most important are assimilation, dissimilation and differentiation.

Assimilation.—This type of change often occurs in clusters of homorganic consonants (Anglo-Saxon *lamb* has become *lam[b]*), it arises also in other cases, usually where the two elements have something in common, as with Latin *octo*, which has become Italian *otto* (cf. also Latin *septem*, Italian *sette* "seven"; Latin *irrumperē* "break into" from *in* + *rumpere*, etc.). Vocalic elements may be similarly treated: Diphthongs may be fused into single vowels; e.g., Danish and Swedish *ben* "bone" from older *bein* and still older *bain*. Assimilation at a distance is also found, not so frequently between consonants as between vowels: e.g., Latin *quinque* "five" from an older **penque*; cf. Greek *pente*, Sanskrit *pánca* (an asterisk denotes a hypothetical form whose existence is inferred). A well-known case of such assimilation is the metatony (or umlaut) of the Germanic languages, where a vowel of an unstressed syllable changes the stressed vowels: e.g., common Nordic *gastiR* "guest" (*R* denotes a palatal vibrant); Old Norse *gastr*, *gestr*, where the unstressed vowel has disappeared; or Old Norse *mǫgr* "son" from *maguR* (Gothic *magus*); *langi*, *lengi* "for long" (where the *i* remains; cf. Gothic *laggei*); *lykr* "you shut" from **lūkiR* (Gothic *lukis*); *hialdr* "fight" from common Nordic *heldaR*, etc. Assimilation of consonants to vowels is also common. Guttural stops are usually influenced by front vowels, first becoming allophones and sometimes developing into affricates and spirants. The assimilation to front vowels may be extended to all consonants and, when the original condition of position before a front vowel is changed (e.g., through the disappearance of this vowel), the palatal consonant may become a phoneme contrasting with an ordinary consonant. This has taken place in Irish, Scottish Gaelic and Slavic, and also in certain Asian languages. Similarly, consonants may be velarized before back vowels.

Rhythm plays a great role in this development. A dominating syllable, which bears the stress or is long in languages with free quantity, may shorten or absorb a weak syllable. Such a change is usually called syncope. In a final syllable a vowel may also be weakened because of its occurrence before the pause; in this position a consonant may become implosive and finally be lost. In languages with a strong stress accent the vowel is often reduced to a midvowel of more or less indeterminate timbre, usually transcribed *ə*. In languages with free quantity the shortened vowel is reduced in length and forced upward as a high vowel, which, other things being equal, is shorter than a low one. The first kind of development has reduced the length of English words: e.g., *bind*,

Middle English *binde(n)*, Anglo-Saxon *bindan* and other infinitives; cf. *reel*, Anglo-Saxon *hréol*, from **hrehula*. Instances of the second type are found, for example, in Latin, where *novitas* "newness" goes back to **newotā(t)-*; cf. *novus* "new" (from **newos*); *occupo* "I take possession of"; *incipio* "I begin"; compounds of *capio* "I take." In some cases the vowel has disappeared completely; e.g., *surgo* "I lift up" (beside *surrigo*); *porgo* "I stretch," "I spread out" (beside *porrigo*); cf. *rego* "I guide," "I conduct."

Dissimilation.—The same rhythmic tendency leads to change in identical or partly identical phonemes which are separated by other phonemes; this is called dissimilation. One of two consonants may be dominating physiologically, e.g., through being part of a stressed syllable or through being protected by a preceding or following consonant; or functionally, by belonging to a separate morpheme. The first *r* belonging to the stressed syllable and "protected" by another consonant immediately following it has dissimilated the second in Irish *corneal* and Welsh *cornel*; the two borrowed from Anglo-Irish and Anglo-Welsh *corner* respectively. In English *mulberry*, however, which goes back to an older *murberi* and which is either borrowed from French *mûre* or else represents Anglo-Saxon *morberie*, the dissimilation which from the physiological point of view might be expected to affect the second *r* has been reversed on account of the influence of *berry*. The first element is a loan from Latin *morus*.

Differentiation.—The process of differentiation counteracts the tendency of assimilation and may take place between vowels, between consonants and also between a vowel and a consonant. It happens, for example, that in part of a dialect area a diphthong, e.g., *ei*, becomes a monophthong through assimilation-fusion (*ei* becoming *e* or *i*), whereas in another part of the area it develops into a stabler diphthong (*ei* becoming *ai*). Similarly, *-nm-* may be differentiated. Latin *anima* became *anma* and then *alma* in Italian, Spanish, Catalanian and Portuguese and *arma* in Sicilian. Latin *k* before a front vowel became identical with *t* in the same position; the palatal *t'* developed a consonantal *y* before the front vowel. This *y* was differentiated into a sibilant *s* or *š*; e.g., Latin *cera* which became Italian *cera* (pronounced *tšera*) and French *cire* (where the *ts-* has been assimilated into *s*). The development of the *t'* is a special case of differentiation called segmentation, the breaking of a phoneme into two; this often protects one phoneme against another. In Latin, *-m-* before a dental became *-n-* by partial assimilation: e.g., *centum* "a hundred," which originally had a labial nasal as shown by Lithuanian *šimtas*; *eundem* "the same," a compound with *eum* "him"; *septendecim* "seventeen," from *septem* + *decem*. In *emptus*, *sumptus*, past participles of *emo* "I buy," *sumo* "I take," the influence of the present has led to a differentiation of the voiceless glide at the end of the *m* into a full phoneme *p*. This *p* is also found before *s* in the perfect: *empsī*, *sumpsī*.

Long vowels in languages which contrast long with short vowels may be broken up into diphthongs, the final wavering of the articulation being differentiated into a diphthongal element or a consonant phoneme. The development of the original long vowels in English is a case in point.

Metathesis, i.e., transposition of phonemes, may take place when the sequence causes difficulty. Irish did not have the sequence *-ts-*; therefore English *-ts-*, *-ds-* became Irish *-s't'-*; e.g., *briste*, Eng. *breeches*; *maistín* from *match*; *bagaiste* from *baggage*; *caraiste* from *carriage* (the newest loans have *-t's-*; e.g., *bitseach* "bitch," a fact which testifies to the increased influence of English).

Contrasting series of phonemes may react on one another, as in Old Celtic, which had a difference between tense and lax consonants. The former appeared in initial position and in certain clusters, the latter in intervocalic position and in certain other clusters, so that they were further weakened. In British the intervocalic voiceless stops became voiced and the voiced stops became spirants; in Gaelic, voiceless and voiced spirants developed: e.g., Irish *múch* "smoke"; Welsh *mug* "smoke"; Breton *moug*, *mog* "fire" (cognate with Eng. *smoke* from Anglo-Saxon *smoca*); Irish *cath* "combat," "fight"; Welsh *cad*, Gaulish *Catu-rix* (a name

meaning "king of the combat") and *Caturiges*, name of a tribe; Irish *bodhar* "deaf"; Welsh *byddar*, Breton *bousar*, cognate with Sanskrit *badhīrās* "deaf." In Old Norse *e* became *ea*, *ia* as in *hialdr* above; but *u* did not become *ui* in **lūkiR* because of the system of quantity: *ui* would have created a third degree of quantity, which is a very rare phenomenon.

Theories of Phonetic Change.—When precise phonetic description began in the 19th century, a theory arose that language was subject to phonetic changes following laws similar to the laws of nature. These "phonetic laws" were said to be without exception, to affect the same phoneme or phoneme sequence in all positions, and to last a certain time, after which they ceased to be active. Exceptions were explained as due to analogy and to the influence of forms in which the conditions of the "law" did not occur. These views were never accepted by all scholars and have now been abandoned. The process of change is in fact psychophysiological; its nature is largely determined by linguistic structure. Precise dialectal investigation has shown that it starts in a few words used, perhaps, only by a single individual and then extends to other words and to other individuals geographically and socially. If it affects a phoneme as such, it may be complete. In standard French, for example, the old palatal *l* (that of Italian *figlio*) has become the consonant *y* (*filie* pronounced *fiy*). All palatal *l*'s have disappeared, but they have not all necessarily become *y*.

Since the phonemes of all languages belong to the same types (though certain types are of limited extension, such as the clicks) and since the speech organs and the brain are of the same nature in all men, changes in the phonemic systems, as already indicated, may be classified into types. In such cases as those of dissimilation which occur in very precise psychophysiological conditions, it is possible to formulate "laws" which express a general experience; for example: of two intervocalic consonants the first is dissimilated (e.g., Italian *veleno* "poison," from Latin *venenum*; Old Irish *araile* "other," from *alaille*). The "law" takes a given form in a given language, according to the nature of its system (*n-n* > *l-n* in Italian, *l-l* > *r-l* in Irish, etc.; > signifies: is changed into). The "law," of course, does not lay down a rule but merely predicts that any change will likely take a certain form.

Grammatical Changes.—These are very often the result of phonetic-phonemic changes. In the older Indo-European languages, endings of cases and verbs came in the final syllable or syllables of the word. As these syllables disappeared, the formal system of the language was reduced. Prepositions and word order replaced the cases, pronouns the verbal endings. But other factors may also favour change; for example, two cases in old Indo-European might have had overlapping functions, with the result that one of these became obsolete; other forms fell into disuse for different reasons.

Inventory Changes.—Such changes occur through adoption of new words and the disappearance of old. Words are born, die and are borrowed more or less freely by all languages. Inventions and social developments create new words. In the countries of western culture most of these words are composed of Latin-Greek elements. Particularly striking examples are the terms introduced in the 20th century through the invention of aviation, radio, television and nuclear physics as well as through political movements such as communism and international co-operation. Words denoting outmoded objects and ideas tend to disappear.

Changes of Meaning.—These involve both extension and restriction of meaning. Understanding of this process requires study of the associations between vocabulary-words and sentence-words. The first are called associative; they associate words of similar meaning or form within the vocabulary: e.g., *intellect*, *mind*, *brains*, *understanding*, *comprehension*, etc.; or words ending in the same suffix, such as *-ness*, *-sion*, *-tion*: *boldness*, *awareness*; *caution*, *action*, etc. A writer constantly makes use of such associations. Sentence-word associations, called syntagmatic, are those which lie behind the scheme of distribution of the different words of the sentence and make it possible for one element of it to call forth the rest. Associations of meaning or form explain how meanings may pass from one object to a new one or from one situation

to another, provided that the two have certain elements in common. English *bead*, for example, originally meant a prayer; it was used of the rosary and, in the plural, came to designate it, the singular form coming to mean the perforated ball on the string of the rosary. From this the word was transferred to other similar objects. The word *foot*, which originally meant the lowest part of the leg beneath the ankle, has likewise been transferred to parts of objects similar in form, function or position, such as the support of a table, the base of a mountain, etc. *Meat* originally meant food in general (Norwegian and Swedish *mat* still do), but having been used in contexts where this referred to the flesh of an animal, it acquired its present restricted meaning. The French negative particle *pas* goes back to Latin *passus*, "step." As *pas* is usually combined with *ne*, "not," the negative meaning has passed on to it. The Scandinavian *ikke*, which originally signified "something" (Old Norse *eitgi*), is now the negative, having received this connotation from a *ne* which later disappeared.

III. THE EXTERNAL HISTORY OF LANGUAGE

The external history of language deals with such problems as the role of language in society, the geographical extension of languages, the division of languages into dialects, and the rise of standard languages and of literary and international languages. It is not always possible to keep problems of the external and internal history of a language apart because they may be closely related.

A. LANGUAGE AS A SOCIAL FORCE

Language is probably the greatest force of socialization that exists (E. Sapir). Through it knowledge is passed on from generation to generation. The development of implements can be understood only through the existence of language; some form of it, very different from even the most "primitive" of today, must therefore have existed at the time when the first implements were made.

Language is the medium through which the child becomes a member of his society. There seems to be a general sequence of steps by which he learns to use a linguistic system, especially the sounds. The sound categories are mastered at intervals varying according to the child, but in the same order. Dental consonants appear before velar (e.g., *t* before *k*). The first vowel is *a*, the first consonant a labial. The first consonant contrast is that between an oral and a nasal (e.g., *p:m*). It is followed by one between labials and dentals (e.g., *papa-tata* or *mama-nana*). Then comes the contrast between an open vowel (*a*) and a narrow one (*i*; e.g., *papa-pipi*), and so on. (Note that aphasics lose their sounds in the reverse order.)

In the course of its history a language tends to vary geographically and to split into dialects if there is no central counteracting influence: from this results the extreme linguistic diversity of the world. Regions in which no higher civilization has developed are usually peopled by a great number of tribes speaking different languages or dialects (for the term "dialect," see below). Whether all languages have one common origin cannot be traced. At all periods the relations between languages and dialects have been upset by the migrations and conquests of peoples. North American Indian languages have expanded southward, Asian languages westward into Europe, European languages eastward into Asia, north European languages into south Europe, etc. In modern times such languages as Spanish, Portuguese, English, French, Dutch and Russian have conquered vast territories. In the more composite societies languages tend to vary within themselves and to characterize different social groups or layers. The refined language of literate societies is usually strongly influenced by the written language and becomes opposed to popular or vulgar language. Different crafts and trades use special vocabularies. There are thieves' and other slangs and secret languages. In certain societies different social classes use quite different languages.

The question whether any special relations exist between the structure of a language (or important features of it) and that of the society which uses it is exceedingly difficult to answer. A linguistic system may remain more or less unchanged in its most

important elements while a society is undergoing very great changes. Russian, for example, has remained the same despite the Revolution of 1917, apart from relatively minor changes in vocabulary and style and the dropping of some literary grammatical forms. Languages must be stable to serve as vehicles for general communication.

Causes of Linguistic Change.—Semantic changes are often caused by social conditions and evolution. When a word passes from the general language of a society to a restricted group, its meaning tends to shrink; the opposite happens when it passes from a restricted group to the general language. Latin *ponere* "put," *cubare* "to lie down," *trahere* "to draw," *movere* "to move" remained in the language of the peasants and acquired the meanings: "to lay eggs," "to brood," "to milk," "to molt." Thence they passed back into general usage and re-extended their meaning. Similarly, the verb *arrive* has been borrowed from French *arriver*, itself derived from nautical vocabulary (Latin *ad-ripare* "to come to the beach").

The causes of phonetic-phonemic changes, however, are largely unknown, except in cases where a population adopts a new language, when speakers will carry over traits from their original tongue. "Economy of effort," climate, etc., cannot explain change. Succession of generations is not in itself a cause, but nevertheless an important element in the process. At first the new and the old forms or words are used side by side. As the new become more and more frequent the use of the old is correspondingly restricted until a generation of young people grows up that has never heard them. Thus phonetic-phonemic changes in a language with a long tradition must be due to extralinguistic causes, often favoured by the conditions of the linguistic system itself. Changes may destroy its balance, and this will increase the tendency toward further change.

Grammar and Social Needs.—By means of the distinction between nouns, adjectives and verbs, objects (and beings), qualities and actions are differentiated. This classification of phenomena is of fundamental importance to thought: users of languages that have other categories, or other limits between them, will think differently because their referents differ. Benjamin Whorf compared the categories of Hopi with those of the western European languages. He contrasted the western European system of time, expressed in three tenses placed in a row (past—present—future), with that of Hopi, which has no tenses, but assertions (validity forms), aspects and modes (clause-linking forms). The validity forms denote that the speaker (not the subject) reports the situation (corresponding to European past and present), or that he expects it (corresponding to European future), or that he makes a nomic (customarily or generally valid) statement (corresponding to European nomic present). The aspects denote different degrees of duration and different kinds of tendency "during duration." Need to express sequence of events does not arise until there are two verbs, *i.e.*, two clauses; and then the modes denote relations between the clauses, including relations of later to earlier and of simultaneity. The modes and aspects may be supplemented with many detached words.

In the Indo-European languages, for example, the terms *summer*, *winter*, *September*, *morning*, *noon*, *sunset* are nouns and are "objectified." In Hopi they are not nouns nor special fixed parts of speech like German *des Abends* but a part of speech in themselves, different from verbs, nouns or adverbs; they may be called "temporals." They are best translated by "when it is summer," etc. One does not say, "this summer," but "summer now," "summer recently," etc.

Such contrasts between linguistic categories raise the question whether they imply a different way of viewing the world or just a difference in emphasis. Some linguists think the first, others the second. The study of these problems was only beginning in the early 1960s. Still, where new categories are created they correspond to some social need. It is significant, for example, that while a simple society of food gatherers such as the Australian aborigines does not usually have a series of numerals (for they have nothing they need to count), as soon as a society is food producing, numerals become necessary.

Many modern Indo-European languages, especially those of western Europe, have had their inflections greatly reduced. The whole system of cases has disappeared and the number of verbal forms has decreased. Some linguists think that this development must be due to the increase of abstract thought: it cannot be explained simply by the disappearance of the endings. Armenian was subject to a similar reduction of its case endings, but has re-created them. This phenomenon too is as yet unexplained.

B. COMMON AND HYBRID LANGUAGES

At an early period, peoples of different native tongues came to adopt special forms of language to make communication easier, especially for commerce. This kind of language is now called a *lingua franca* (*q.v.*). Such languages are still widely used. They may begin as national languages as, for example, Awar in the Caucasus or Swahili in Africa. Often they are so-called minimum or rudimentary languages with a very small number of grammatical forms of mixed origin. The Russenorsk used by Norwegian and Russian traders until World War I was of this kind. Its very simple and reduced grammar had Norwegian, Swedish and Russian elements and a very composite vocabulary, so that the Russians thought that they were speaking Norwegian and the Norwegians that they were speaking Russian.

Standard Languages.—When languages of civilizations with great literatures arose, they were able to spread beyond their national homes and oust a great number of local dialects and languages; great examples are Ionian-Attic, Hellenistic Greek and Latin. The same trend continues in modern times.

In general, these "common" or "standard" languages expand from some administrative or cultural centre, often helped by the growth of literature. Standard Italian, for example, which has been called *lingua toscana in bocca romana* ("a Tuscan language in a Roman mouth"), was largely created by the work of Dante. The Frankish dialect of the French kings and of the Île de France became standard French, which has ousted the dialects from a region extending approximately 200–500 km. from Paris. Modern German goes back to the language of the Saxon chancellery, which Luther chose for his translation of the Bible. An author may even create a new literary language. The Norwegian poet and scholar Ivar Aasen deliberately constructed *landsmål* (now officially called *New Norwegian*), one of the two standard languages of Norway, on the basis of the western dialects of that country. There exists an important literature in this language; but the other Norwegian (*riksmål*) predominates in administration and journalism.

In many states, especially from the 19th century onward, the administrative language has become a national symbol to be forced on minorities, who often oppose it because they regard their own language as part of their separate social entity.

The languages of great civilizations may have much influence beyond the areas where they are spoken, through borrowing or translation of their words; as, for example, with Chinese and Sanskrit in the east. In the west, words for new objects or ideas are usually formed from Latin and Greek elements, but words from modern languages are also taken over. In Scandinavia, for example, it is possible to follow the sequence of cultural influences through the loans: Old Celtic, Latin, Anglo-Saxon, Medieval French, Low German with Dutch, High German, French and English following one another.

Medieval Latin had a profound influence on the new literary languages of Europe. A literary language may continue to be spoken in certain circumstances long after it has ceased to be current speech. Sumerian continued as a religious and learned language in Mesopotamia long after it had been supplanted in popular use by Akkadian. Similarly Greek and Church Slavonic are still used in eastern liturgical worship and Latin in western; while Latin was the international language of European scholars during the medieval period. Such languages may also be used for diplomacy, as were Akkadian, Greek and Latin; followed by French from the 18th century, with the addition of English in the 20th. These two languages have remained the foremost in international communication, French especially in southern Europe and South America, English elsewhere. But Russian, Spanish and Chinese are advanc-

ing and have been used, as, for example, in the United Nations. Arabic after World War II has gained international importance; German, through technicians, scientists and scholars, has retained considerable influence.

The prestige of a language of civilization enables it not only to exert influence without the support of political power but also to resist contrary political pressure, so that it may even be adopted by military conquerors; as was Latin by the Teutonic invaders of the Roman Empire. Likewise the Norse Vikings who gave their name to Normandy adopted French very quickly.

Artificial languages have been created to facilitate international communication (see INTERNATIONAL LANGUAGE).

C. FORMATION OF DIALECTS

When the Roman Empire broke up, spoken Latin became differentiated, and during the medieval period there arose large dialect groups each characterized by its own main traits. Similar dialect groups are found in other parts of the world where they go back to a common language known by tradition or inferred from linguistic forms (see below). The term dialect has various connotations. It is generally used to mean a variety of language characteristic of a locality or of a social group or class seen in relation either to a standard language or to other varieties with which it is historically connected. It may or may not have a literature. The individual speaker's variety of the language of his community is sometimes called a "dialect," but "idiolect" is a better term. The demarcation between dialect and language depends on social and historical conditions and not, as is sometimes argued, on the ability of speakers of the different varieties to understand one another. Educated Danes, Norwegians and Swedes do understand one another; but they use different standard languages with different traditions dating back to the time when writing was introduced into Scandinavia. Sometimes a language seen in its relation to the linguistic family to which it belongs is called a dialect.

It is characteristic of the larger dialect groups that there are no sharp limits between the different varieties within the group like the frontiers between, for example, French and German, Swedish and Finnish. In principle every word and every grammatical form has its own extension, or isogloss, within a great dialect area. Traveling through the area of a dialect group, for example the French, the German or the Scandinavian, one usually finds small differences between neighbouring localities, but the longer the journey the greater the contrast between a given locality and the point of departure. The changes in phonemics, morphemics and vocabulary are gradual. But it happens also that sharper limits can be observed where there are special population changes. Here innovations usually start from some central points such as important towns and follow lines of communication. Archaic features may persist in the outlying zones.

The Tracing of Linguistic Relationships.—From the above considerations, it is to be expected that various languages which are now very different from one another may once have been one, just as the Romance languages were once popular Latin. Special linguistic methods, elaborated mostly for the study of the Indo-European languages, enable one to determine the genetic relationships between languages by a comparison of their forms. These relations permit the supposition that there once existed a parent language. Full knowledge of a root language cannot be gained in this indirect way, but certain important traits of it may be determined. For it is extremely unlikely that the grammatical morphemes should be expressed by the phonemes just by accident. It is not necessary that these morphemes should be phonemically identical—they rarely are—but when the phonemes can be shown to correspond in a way that is explained by a common origin, it is evident that the mor-

phemes in question are only different forms of a common original: as, for example, in Latin *genus*, *generis* "birth," "descent," corresponding to Greek *génos*, *généos*, Sanskrit *jānas*, *jāna-as*; etc. Compare further the forms of the verb "to be" in the various persons singular and plural.

Sanskrit	sing. 1 <i>ásmi</i> , 2 <i>ási</i> , 3 <i>ásti</i> pl. 1 <i>smás</i> , 2 <i>sthá</i> , 3 <i>sánti</i>
Greek	<i>eimi</i> , (= <i>emi</i>), <i>eĩ</i> (from * <i>esi</i>), <i>ésti</i> <i>eimén</i> , <i>ésté</i> , <i>eisí</i> (Doric, <i>enti</i>)
Latin	<i>sum</i> , <i>es</i> , <i>est</i> , <i>sumus</i> , <i>estis</i> , <i>sunt</i>
Old Irish	<i>am</i> (from <i>esmi</i>), <i>a-t</i> , <i>is</i> <i>ammi</i> , <i>adib</i> , <i>it</i> (from * <i>sentí</i> , Old Welsh <i>hint</i>)
Gothic	<i>im</i> , <i>is</i> , <i>ist</i> , pl. 3 <i>sind</i> (from * <i>sentí</i>)
Old Lithuanian	<i>esmi</i> , <i>esi</i> , <i>esti</i>
Hittite	<i>e-es-mi</i> (= <i>esmi</i>), 3 sing. <i>e-es-zi</i> (= <i>eszi</i>), 3 pl. <i>a-sa-an-zi</i> (= <i>asanzi</i>)

By proceeding in this way it has been possible to posit such language families as the Indo-European, the Semitic, the Finno-Ugrian, etc. Correspondences between phonemes are the necessary prerequisite for the establishment of linguistic parentage, as, for example, in Indo-European. A list of vowels in the Indo-European languages can be drawn up as in Table III, from which it is possible to conclude that Indo-European had *e*, *o*, *a*. Similarly, Table IV shows how the originally voiced stops correspond in the same language family; this indicates the following system in Indo-European: *b* : *d* : *g* : *g^h*.

When, as for Indo-European, it is possible to draw up a number of such tables, where the corresponding phonemes occur not only in lexical but also in grammatical morphemes, the conclusion is easy. But neither phonemic nor lexical correspondences alone are decisive indications of linguistic parentage. There may be regular phonemic concord between the loan words of a language and the source words in the lending language. On the other hand, a language may lose most of its vocabulary without losing its grammatical framework.

D. RECIPROCAL INFLUENCE OF LANGUAGES

Languages, especially neighbouring ones, may show general similarities which are not due to genetic relationship. Conversely, genetically related languages may belong to different types; e.g., English and Lithuanian. The similarities appear in areas exposed to the same cultural influence, where there will be groups of bilingual speakers who introduce loanwords, expressions and constructions from one language into the other. The western European languages exhibit many corresponding traits which do not go back to the earliest period. A striking example is the spread of the definite article. This is found in Late Egyptian and Semitic, in Greek (later than the Homeric poems); in Late Latin; in Basque; in Irish and Welsh from the earliest periods and in Teutonic, where the Scandinavians must have introduced it in the 10th century. Linguists used erroneously to regard such cases as the result of parallel developments. The concrete form and the etymological origin of the article differ from language to language. In Latin and Romance it is a form of the pronoun *ille* (in some cases *ipse*); in Celtic, an old pronoun **sindo-*; in Scandinavian, both the preposited *hin* and the postposited *-inn* are original demonstrative pronouns.

In cases where two languages confront each other in the same

society, the dominating one having to be learned by the original population or by people brought together who speak different languages, the influence may take two main forms. If the two languages are very different the population that adopts the new one will carry over both words and categories from its original speech, expressing them with elements from the new language. The phonemic-phonetic system will also be strongly influenced, though phonemes not found in the new language are seldom carried over from the old. Anglo-Irish uses the verbal aspects of Irish; Breton-French in large parts of Brittany stresses the penultimate syllable as in Breton, and the voiced stop, labial and guttural spirants *x* and *z* are devoiced before a pause. In that position *tad* "father" is pronounced *tat*. Creolian French is a form of French completely remodeled to fit the general scheme of western African languages, though no African elements and very few words have been taken over. Haitian French has no temporal tenses, but uses aspects. The durative aspect is expressed by the prefix *apr-*, the momentaneous by *fek-*; e.g., *m-apr-alé* "I am going," from French *moi-après-aller*; *m-fek-rivé* "I have just arrived," from French *moi-(ne) fais-que-arriver*.

When the two languages are already closely akin, so that their speakers understand each other without great difficulty, the result may be a mixed language, having grammatical forms of different origins. In the 18th-century Russian of the Muscovite state, for example, three languages co-existed: pure Church Slavonic, used in worship and in religious writings; Russian proper used for business and in the home; and simplified Church Slavonic, called Slavo-Russian, for secular literary speech and writing. This third language had a purely Church Slavonic vocabulary but avoided and eventually eliminated certain "scriptural" words. Its grammar approached that of conversational Russian, avoiding certain Church Slavonic forms and using specifically Russian flexions and syntactic constructions. It and the business language were perceived not so much as distinct languages but as different styles of the same language; whereas Church Slavonic was a separate linguistic entity. By the beginning of the 19th century these business and literary forms had coalesced, the former becoming more literary and the latter more russified, some of its Church Slavonic lexical elements being replaced by Russian.

A similar process had taken place in Norway, where Danish was adopted as the literary language when Old Norse became unintelligible (the two countries being united under one king since the 14th century). But the literary language was used as a spoken form only on solemn occasions, as for preaching or the public reading of official declarations, when it was called the "official" or "solemn" language. Its phonetics were Norwegian; it used the Norwegian lexical tones, unknown to Danish; and had many other Norwegian traits. Country people and lower-class townspeople spoke dialects derived from Old Norse. The language of the towns was more subject to foreign influence, especially lexically, than that of the country. Better-off people, such as merchants, intermingled influences from the "solemn language" with the dialect of their town; the result was called the "intermediate language." Then, in the 18th century, in the towns of the southeast, the "solemn language" and the "intermediate language" coalesced into a common spoken standard form. This had grammatical forms of both Danish and Norwegian origin and a vocabulary with Norwegian words especially for practical everyday life and Danish words for spiritual or literary matters. The amount of Danish grammatical forms in Norwegian has varied somewhat, but has been gradually reduced, especially in the 20th century, by conscious policy of the authorities after the adoption of the spoken language as basis for the written language by the reform of 1907. This written and spoken language is called the *riksmål* (i.e., language of the realm; officially the "book language"). The Norwegianizing of the language has made headway owing to competition with the other official language, the *landsmål* (i.e., language of the country; officially New Norwegian).

E. GROWING TIME

Since 1951 theories have been set up to measure how long it takes for a dialect to grow from its parent language. The glotto-

chronological method is mainly statistical; cases where the time lapse is known are studied in an attempt to establish a general formula. Such a theory would do (less accurately) for language what carbon-dating does for archaeology. Linguistic change is slow: 3,000 years lie between modern Greek and Homer. Moreover, the rate of change is not uniform. The formulas offered do not agree very well with known facts. So far mainly lexical items have been studied: basic root morphemes, names of family relationships, parts of the body, numerals up to ten, simple adjectives like good and bad, demonstratives like here and there; all of these occur in almost all languages. (See *International Journal of American Linguistics*, 21:121-137 [1955]; for a critique of the theory, see *Language*, 32:48-60 [1956] and *Current Anthropology*, 3:115-153.)

LINKAGES, in mechanics, are combinations of links or bars, in general connected by pins, slides, rollers or screws. If the combination is such that no relative motion can exist between the parts a structure results. If the links can move relative to each other the linkage becomes a kinematic chain. Specific forms of kinematic chains are useful when the motions of the links are controlled so that constrained relative motion results. Such linkages are commonly referred to as mechanisms when the transmission of energy is not important.

Many linkages, or mechanisms, are used to obtain specific motions with little regard to the performance of work. Such devices as watches, typewriters, record changers, mechanical computers and working models are of interest for the relative movements of the parts, not the energy involved. Machines, however, commonly involve the performance of work or the transmission of power to some useful end. Thus, practically all machines may be thought of as being mechanisms or linkages in various combinations in which work or energy is significant. The automobile, for example, is made up of many linkages, some of which—parts of the engine and transmission—function as machines, while others—steering

FIG. 1.—FOUR-BAR LINKAGE

and throttle linkages—are present primarily to provide certain desired motions of the parts.

Historical Background.—Many linkages in common usage have had their origin in centuries past. From the time of the great early Egyptian civilizations, the minds of men have sought means to produce motions not obtainable with the human hand alone. Multiplication of effort, faster speeds, more complex motions over greater distances or in smaller spaces have been the goals of such men as Archimedes, Hero of Alexandria, Leonardo

FIG. 2.—DRAG-LINK MECHANISM

da Vinci, James Watt and others.

Hinged tongs were in use as early as the 6th century B.C. The screw of the Archimedean screw was invented, according to some authorities, around 400 B.C., and was in use in Egypt before Archimedes' time. By the 1st century A.D. the lever and the screw press were in use for crushing grapes. The ratchet and pawl (see RATCHET AND PAWL) were shown in types of crossbows described by Hero and Philo in the same century. A linkage for operating a fascinating hydraulic organ also was described by Hero. But for nearly 1,000 years, from about A.D. 400 to 1400, little advance

FIG. 3.—IDEAL RELATION OF AUTOMOBILE WHEELS WHEN TURNING A CORNER

was made in the use of mechanisms and linkages.

Then the gradual awakening of western civilization and development of the industrial age stimulated many new and improved devices. Weaving and spinning machines and machines of war occupied Da Vinci's thoughts with ingenious and far-reaching results. Stamp mills and water-driven bellows used crude linkwork in the 16th century, the joints being constructed of interlocking

FIG. 4.—SLIDER-CRANK LINKAGE

eyes, as are the links of a chain. The Industrial Revolution saw the rise of many new linkages and led into the development of complex devices such as the Stephenson, Walschaert and Joy locomotive valve arrangements.

Better methods of analysis and precision of manufacture in the 20th century gave rise to increasingly precise and complex linkages in typewriters, computing devices, packaging equipment and manipulating mechanisms used to position, hold and transfer products of industry.

Some giant linkages have been created, such as in some of the mining equipment of the 19th century. A mine pump in Germany is said to have had a connecting rod over 7,200 ft. long. In 1682 a French fountain display incorporated a linkage 2,000 ft. long.

In existence in the mid-20th century was a water wheel 72 ft. in diameter that drove a mine pump on the Isle of Man. The 600-ft.-long connecting rod was disconnected during the 1930s, but the

wheel remained in operating condition. Some of the largest linkages continue to be employed in mining, as in the giant shovels used for removing overburden in strip mines.

Classification.—Attempts have been made at classification of linkages using rules such as the number of degrees of freedom of the chain. A link with unrestricted motion is said to have six degrees of freedom since it can move in any one of three mutually perpendicular directions in space and can rotate in any one of three mutually perpendicular planes. Such criteria, however, can distinguish between structures and mechanisms in general but may fail for special cases

FIG. 5.—HAND-PUMP LINK MECHANISM

where a point-by-point analysis will be required.

Basic to all linkages are the types of joints or pairs employed. Such pairs may be classified as higher pairs when line or point contact between the members is indicated. Examples of such pairs are ball bearings, cams and flat-face followers, pins in slots and gear teeth. Lower pairs are pairs with geometrically similar areas in contact, such as plain bearings, a piston in a cylinder, and ball and socket joints.

A further description is provided by the terms turning pairs (pin joints, sleeve bearings); sliding pairs (piston in cylinder, gears); and rolling pairs (balls and races in ball bearings, railroad-car wheel on rail). A special pair having relative helical motion is known as a screw pair, as exemplified by the common bolt and nut.

Common Linkages.—The study of linkages generally begins with the analysis of some of the more common types and progresses to the more difficult problems of synthesis. One basic linkage is the four-bar linkage or quadric-crank mechanism (see fig. 1). This consists of four links connected by pin joints with one link (I) generally stationary. Link II is usually called a crank, link IV a lever, and link III a coupler. By varying the proportions of the links, various motions are transmitted to link IV as well as to points on link III. Thus, in fig. 1 the crank can make a complete revolution while the lever oscillates as shown by the dotted lines. This linkage can be used as a simple device to translate rotation into oscillation which, with a ratchet linkage, will produce an intermittent motion.

By altering the proportions the drag-link mechanism, fig. 2, may be created. Here links II and IV both rotate completely, II at constant speed and IV with varying speed. This mechanism, when coupled with an additional link V, creates a type of quick-return mechanism commonly used in a Dill slotter, a machine for cut-

FIG. 6.—WHITWORTH QUICK-RETURN MECHANISM

ting keyways in shafts. If the links are paired with opposite links of equal length, a parallel linkage is formed such as is used in the cranks and parallel rod of a locomotive or in the universal drafting machine, which is widely used in place of T squares and triangles. The automobile steering mechanism has generally employed a four-bar linkage to obtain the necessary differential motion of the two front wheels. Ideal performance dictates that the two wheels should operate as in fig. 3 in making a turn. Practically, a compromise usually is reached that provides for turning the wheels through unequal angles but does not attain a common centre of curvature at Q for the paths of all four wheels.

The idea of inversion is very important in the study of linkages. A mechanism or linkage is said to be inverted when the originally fixed or reference link is permitted to move and a different link is held fast, without changing the basic proportions of the linkage. Such inversion changes the motions of all links relative to a fixed reference system but does not change the motions of the links relative to each other.

A quadric-crank linkage in which the lever, link IV, is permitted to become infinitely long is represented by the slider-crank mechanism, fig. 4. One of the pin joints has thus been replaced by the rectilinear sliding pair. In this form it is the familiar crank-shaft, connecting rod, piston and cylinder of the internal-combustion engine, air compressor or refrigerator compressor. Mathematical and graphical techniques have been developed to analyze the motions of this mechanism quickly and accurately.

Several inversions of this interesting and versatile linkage have been put to use. With link IV fixed, the common hand pump, fig. 5, results. By holding stationary the connecting rod, an oscillating piston and cylinder mechanism may be obtained, such as has been used in marine engines. Radial aircraft engines in which the cylinders rotated about a fixed crank were obtained from a fourth inversion of the basic slider-crank linkage at the time of World War I.

Inversions of the slider crank are frequently combined with additional linkage in modern machinery. The crank shaper, and the Whitworth quick-return mechanism, fig. 6, are devices used in machine tools where a reciprocating motion with controllable unequal times for advance and return strokes of the slider C are desired.

One quite useful variation is the toggle linkage, fig. 7. As the slider C approaches the end of its stroke it is capable of exerting a very large force F with a relatively low force P . By making $AB = BC$ and having F act perpendicular to F' , then

$$\frac{F}{P} = \frac{1}{2 \tan \alpha}$$

Stone crushers, presses, clutches, pneumatic riveters use forms of this device.

Straight-Line Linkages.—The production of a straight-line motion in a plane has intrigued the minds of many scientists and engineers in times past. Exact straight-line motions may be obtained by the Scott-Russell's linkage, Hart's straight-line motion, Peaucellier's movement and the pantograph, fig. 8. However, these devices are not widely used since straight-line motions are generally obtained with slides. In special cases where the slide cannot be mounted at the point that is to move in a straight line, these linkages, particularly the Scott-Russell's, or some type of

FIG. 7.—TOGGLE LINKAGE

approximate straight-line motion linkage, are used.

The classical approximate straight-line motion linkages are generally special cases of the four-bar linkage. The best known of these are Watt's, Roberts' and Chebichev's mechanisms. Some giant dock cranes employed for loading ships are examples of the use of the Roberts' approximate straight-line motion.

The pantograph is useful in the redrawing of maps or other figures to a different scale, several arrangements of this linkage being possible. In fig. 8 point P' will trace the same figure traced by P, but R/r times as large. By joining several such linkages together the common lazy tongs is achieved, a device much used as a telephone support, in toys and in a railroad freight-car unloader.

Steam-engine valve gears, rather complex linkages involving straight-line motions, were developed as the reciprocating steam engine came into use during the 19th century. The Baker valve gear became one of the most popular of these linkages for the steam locomotive.

Space Linkages.—The conic four-bar linkage enables relative spherical motion to take place between the four links. If the axes of the four pin joints are not parallel but have a common intersection at a finite distance the members remain movable. The different forms of plane linkages can be reproduced in the conical form (or space linkage) provided this rule is maintained, with a few modifications to eliminate interference of parts.

One of the most useful of these space linkages is the Hooke's joint or universal joint, fig. 9, used for joining two intersecting shafts. Unfortunately, a varying angular speed ratio results when the joint connects shafts at an angle, though this defect can be minimized by suitable arrangement of two joints and an intermediate section of shafting.

FIG. 9.—UNIVERSAL (HOOKE'S) JOINT

Synthesis.—The problem of proportioning a linkage to perform a given function may be relatively difficult when using a combination other than a simple cam and follower (see CAM). However, many mechanical computing devices have been developed for specific mathematical operations and are in widespread use throughout industry, performing a great variety of production and control operations. See COMPUTER; OFFICE MACHINES AND APPLIANCES.

LINKÖPING, a city of Sweden, the chief town of the *län* (county) of Östergötland, situated on the Stång river near its outflow into Lake Rox, 100 mi. S.W. of Stockholm. Pop. (1960) 65,082.

A bishop's see was established about 1100. At a synod held in 1153 payment of Peter's pence (expenses toward the Holy See) was agreed upon at the instigation of the English legate Nicholas Breakspear, afterward Pope Adrian IV. The coronation of Valdemar, the son of Birger Jarl, took place in the cathedral in 1251. In the reign of Gustavus I Vasa several important diets were held in the town. In 1598 it was the scene of the battle against the Catholic king Sigismund III of Poland, which guarded the Evangelic Lutheran Church in Sweden and secured the Swedish throne for the Vasa dynasty.

The cathedral (c. 1100–1499 and restored in the late 19th century) is a great Romanesque and Swedish Gothic building with a magnificent south portal and late Gothic choir; it has an altarpiece by Maerten van Heemskerck (1543) and a modern one by the Norwegian artist Henrik Sörensen (1931). In the church of St. Lars are some paintings by Pehr Hoerberg (1746–1816), the Swedish peasant artist; the remains of an older Roman church are preserved under the church floor.

Other buildings of note are the 13th-century castle (once the episcopal palace, afterward a royal palace rebuilt in the 16th

FIG. 8.—PANTOGRAPH

century but now the residence of the governor of the county) and the old gymnasium founded by Gustavus II Adolphus in 1627. The Lutheran bishop's palace was erected in 1734 on the old site of a Franciscan monastery. There are also noted diocesan and city libraries and a modern museum (1939) with a picture gallery and collections of prehistoric art. Other museums are the Krogsgården with two peasant houses, "Uncle Adam's House" with late 19th-century interiors and the Valla open-air museum with houses from the old city. The Fountain of the Folkungs by Carl Milles (1927), with an equestrian statue of Folke Filbyter, the mythical ancestor of the famous family, is in Stora Torget (the principal square).

Industrial development came with the building of the Göta and Kinda canals and the Stockholm-Malmö railway. The town is a rail junction with aircraft, freight car and automobile industries. Rope, textiles, tobacco and beer are produced. (B. J. C.)

LINLEY, THOMAS (1733-1795), English musician and father of a large family of musicians, was born at Badminton, Gloucestershire, on Jan. 17, 1733. He studied music at Bath, Somerset, and afterward settled there as a singing master and conductor. From 1774 he was engaged in the management of the oratorios performed at Drury Lane theatre, London. He composed or compiled the music for many dramatic pieces played there, including *The Duenna*, by his son-in-law Richard Brinsley Sheridan. In 1777 he was elected a member of the Royal Society of Musicians. He died in London on Nov. 19, 1795.

LINLITHGOW, VICTOR ALEXANDER JOHN HOPE, 2ND MARQUESS OF (1887-1952), British statesman and viceroy of India from 1936 to 1943, was born at Abercorn, West Lothian, Scot., on Sept. 24, 1887. Educated at Eton, he succeeded his father in 1908 and served with distinction on the western front during World War I. He was appointed civil lord of the admiralty in Stanley Baldwin's government in 1922. He gained considerable knowledge of India's problems as chairman of the royal commission on agriculture in India (1926-28) and of the select committee on Indian constitutional reform that culminated in the Government of India act (1935). In 1936 he succeeded Lord Willingdon as viceroy, with the intention of carrying those reforms into effect. Under the act, the provinces were to be governed by ministries responsible to the elected legislatures. The Congress party, with clear majorities in 5 of the 11 provinces, was unwilling to take office without some assurance that the governors would not use their reserve powers to override the ministries. Linlithgow succeeded in overcoming these scruples, and provincial autonomy was soon functioning smoothly, but he failed to secure the consent of the princes, which was necessary for the establishment of the federal structure provided by the act for the central government. As viceroy, he declared war against Germany in Sept. 1939 before consulting the Indian political parties and thus offended the Congress leaders, who called upon their provincial ministries to resign. They also refused Linlithgow's offer of representation in his executive council; he nevertheless enlarged its size and increased the number of Indian members. In Aug. 1942, in spite of the Japanese menace to India, the Congress threatened a mass civil disobedience campaign if independence were not granted at once. Linlithgow immediately interned their leaders. Outbreaks of violence followed but were soon suppressed. Meanwhile, he had done much to mobilize India's resources. He resigned office in 1943. His pronouncements as viceroy were published by the government of India as *Speeches and Statements by the Marquess of Linlithgow* (1945). (See also INDIA: History.)

After his viceroyalty Linlithgow held various appointments, including the chairmanship of the Midland bank. He died while out shooting on his estate in West Lothian on Jan. 5, 1952.

(KE. A. B.)

LINLITHGOW, a royal burgh (1389) and the county town of West Lothian, Scot., lies on the south side of a loch, 18 mi. W. of Edinburgh by road. Pop. (1961) 4,327. In the 19th century its old-world appearance was much changed by rebuilding, and thereafter by the demolition of other buildings of local architectural merit. The burgh's outstanding feature is the now roofless royal palace, the birthplace of Mary, queen of Scots. This, and

the parish kirk of St. Michael, stand together on the rising ground of the promontory which divides the loch into two nearly equal parts. The palace, a favourite abode of the kings of Scotland, is square in plan. In the centre of the inner close stand the remains of the King's fountain ascribed to James V. At each corner of the palace is a tower with a turnpike turret. The northwestern tower is crowned by a little octagonal cap-house known as Queen Margaret's bower from the tradition that it was from there that the consort of James IV watched for his return from Flodden. The original entrance, an imposing architectural feature, is in the eastern quarter, built in the first half of the 15th century; James V closed this entry and provided one in the south quarter. The north quarter, which contained the queen's suite, having become ruinous was rebuilt for the "homecoming" of James VI (James I of Great Britain) in 1617. The royal apartments, the chapel and the Great hall, otherwise known as the Lyon chamber, were situated on the first floor. The last time the Scottish parliament met in the palace during the plague in Edinburgh, was in 1646. It was burned in 1746 by Gen. Henry Hawley's dragoons.

The kirk of St. Michael, consecrated in 1242, was restored following a fire in 1424. In the early 19th century the open crown spire was removed from the head of the tower, and thus the building was robbed of a typical Scottish feature. In front of the town hall (1662) is the Cross well, erected in 1807 by a one-handed mason. It is a copy of one made at the Restoration by Robert Myne, the king's master mason, who based his design on the King's fountain within the palace.

Modern industries include paper making, whisky distilling and the manufacture of antibiotics. There is an agricultural market.

About 4 mi. S. by W. lies Torpichen, where the knights of St. John of Jerusalem had the chief Scottish preceptory.

(J. S. RN.)

LINNAEUS, CAROLUS (CARL VON LINNÉ) (1707-1778), Swedish botanist, the first to enunciate the principles for defining genera and species and to adhere to a uniform use of the binomial system for naming plants and animals. He was born on May 23, 1707 at South Råshult, where his father was a curate. His love of flowers developed at an early age, and it is recorded that when only eight years old he was nicknamed "the little botanist." He was educated at Växjö and at the universities of Lund and Uppsala, at which latter he qualified in medicine.

BY COURTESY OF THE NATIONAL MUSEUM FOR THE HISTORY OF SCIENCE

LINNAEUS IN LAPP DRESS, PORTRAIT BY MARTINUS HOFFMAN, 1737

It was when he visited Uppsala that he met the veteran botanist Olaf Celsius, an event that had a profound influence on his subsequent career. He was appointed lecturer in botany in 1730 and two years later explored in Lapland for the Academy of Sciences, the results of his journeyings being published in Amsterdam in 1737 as the *Flora Lapponica* and in English by Sir J. E. Smith as *Lachesis Lapponica* (1811). His reputation was established by this and, even more, by the appearance in 1735 of his *Systema naturae* and of the *Genera plantarum* two years later, while the *Species plantarum* did not appear till 1753. (For purposes of nomenclature of flowering plants and ferns the first edition of the *Species plantarum* has been internationally agreed as the starting point together with the fifth edition of the *Genera plantarum* published in 1754.)

The *Systema naturae*, which Linnaeus had shown to Jan Fredrik

Gronovius in manuscript, so impressed the latter that he published it at his own expense. This system was based mainly on the number of stamens and pistils in the flower and the manner in which, if not free, they were joined together. Although artificial, as Linnaeus himself recognized, such a system had the supreme merit of enabling students rapidly to place a plant in a named category, and that at a period when the richness of the world's vegetation was being discovered at a rate which outstripped more leisurely methods of investigation. So successful was it in practice that its facile application was the greatest obstacle to its replacement by the so-called natural systems that superseded it.

Linnaeus visited England in 1736 where he met Sir Hans Sloane in London, Phillip Miller at Chelsea Physic garden and Dillenius (Johann Jakob Dillenius; *q.v.*) at Oxford. He returned to Holland to complete his work on the famous *Hortus Clifortianus* and visited the Jussieu (*q.v.*) family in Paris with whom he became a close friend. A month later he was once again in Sweden and in 1738 settled in Stockholm as a practising physician, in which he attained considerable success. In 1739 he married the daughter of a physician, Sara Moraea, to whom he had been betrothed four years earlier. Two years after his marriage Linnaeus was appointed to the chair of medicine at Uppsala but a year later exchanged this for the chair of botany.

Henceforward his time was taken up by teaching and the preparation of other works. He issued his *Flora Suecica* in 1745 and *Fauna Suecica* in 1746; his two volumes of observations made during journeys in Sweden, *Västgöta resa* (1747) and *Skånska resa* (1751); his *Hortus Upsaliensis* (1748); his *Philosophia botanica* (1751) and his important *Species plantarum* (1753), in which the specific names are fully set forth. In 1755 he declined an invitation from the king of Spain to settle in that country with a liberal salary and full liberty of conscience. In 1761 he was granted a patent of nobility, antedated to 1757, from which time he was styled Carl von Linné. To his delight the tea plant was introduced alive into Europe in 1763. An apoplectic attack in 1774 greatly weakened him, and he died on Jan. 10, 1778, at Uppsala, in the cathedral in which he was interred.

Linnaeus delighted in devising classifications, and not only systematized the two kingdoms of living things but even classified the mineral kingdom and drew up a treatise on the kinds of diseases.

Of his 180-odd works those published during his lifetime were enumerated in R. Pulteney's *General View of the Writings of Linnaeus* (1781). An edition of his correspondence appeared at Groningen in 1830. His widow sold his collections and books to Sir J. E. Smith, the first president of the Linnean society of London. When Smith died in 1828 a subscription was raised to purchase the herbarium and library for the society, whose property they remain.

LINOLEUM: see FLOOR COVERINGS.

LIN PIAO (1908–), Chinese revolutionary, military, and Communist Party leader, was born in the central Chinese province of Hupeh into a family of moderate means that belonged to the educated class. A precocious youth, he graduated from the Whampoa Military Academy (whose president was Chiang Kai-shek) before his 19th birthday and then in 1927 joined the Communist cause, quickly rising to significant posts in the military forces led by Chu Teh (*q.v.*).

Lin was among the major Communist commanders in the battles against Chiang Kai-shek's Nationalist forces in the early 1930s and then commanded one of the principal units on the Long March (1934-35), after defeats by the Nationalists forced the Commu-

nists to flee to northwest China.

Lin became a near-legendary figure in the early stages of the Sino-Japanese War (1937-45) for his exploits against the Japanese Army; wounded in battle, he then spent much of the war period in Moscow. In the postwar years he organized and led the Chinese Communist military forces in Manchuria that defeated the Nationalists there by the end of 1948; striking southward he occupied Peiping (Peking) and then led his armies through central and southern China, culminating in the capture of Hainan Island in the spring of 1950. Although he nominally held significant party, government, and military posts in the early years of the Communist regime, he was incapacitated by ill health (probably tuberculosis) for much of the 1950s.

Lin rose to party Politburo membership in 1955 and four years later succeeded the deposed P'eng Teh-huai as minister of defense. He achieved international fame for his article (September 1965) "Long Live the Victory of the People's War," a blueprint for "wars of national liberation" which called for the "rural areas" of the world (*i.e.*, the underdeveloped nations) to surround and engulf the "urban areas" (*i.e.*, the industrialized countries). Within a year he emerged from the "great proletarian cultural revolution" of 1966 as the heir apparent to Mao Tse-tung, replacing Liu Shao-ch'i. (D. W. KL.)

LINSANG (*Prionodon linsang*), a carnivorous mammal of the civet family (Viverridae), found from upper Burma through the Malay archipelago to Borneo and Java. The linsang, about 30 in. long, is slender in build with short legs and a long, banded tail. Its general colour is pale buff, but the forehead and muzzle are brown, and five broad black or brown bands cross the back. Other longitudinal markings occur on neck and sides. See CARNIVORE: *Cats and Cat Allies (Feloidea): Civet Family (Viverridae); CIVET.* (J. E. HL.)

LINSEED AND LINSEED OIL. Linseed, an oilseed known also as flaxseed, is the seed of a variety of the common flax, *Linum usitatissimum*, which is cultivated principally in the United States, Canada, the U.S.S.R., India and Argentina for its yield of linseed oil and linseed oil meal. This variety of flax has shorter straw, more branches and more seeds than other varieties that are grown primarily for fibre to be woven into linen. World production of linseed is about 140,000,000 bu. per year; the United States, the Soviet Union and Argentina rank among the leading producers. (See also FLAX.)

Linseed is borne in globular capsules, each containing ten long, flat elliptical seeds with slight projections at one end. Sizes vary considerably; typical seeds are about 3-4 mm. long, 2-3 mm. wide and 0.5 mm. thick. Average weights range from 3 to 9 mg. The seeds, usually brown, are smooth and shiny and contain a mucilaginous substance in their outer layer that makes them sticky when wet. Beneath the seed coat is a thick layer of endosperm, inside which the main volume of the seed is occupied by the two cotyledons. Unlike most grasses, mature linseed is devoid of starch granules.

The oil content of the whole seed depends upon several factors, including the type of the linseed, maturity of the seed, locality, soil, temperature, rainfall and other conditions of climate and weather under which the seed is grown. The oil content usually ranges from 33% to 43% in air-dried seed having a moisture content of about 6%.

Linseed oil has a high iodine number (value), which reflects the high degree of unsaturation of its fatty acid radical. The oil is a mixture of the glycerides of linolenic, linoleic, oleic, stearic and palmitic acids. Its high iodine number (usually between 175 and 205, depending on the grade) is due mainly to the linolenic and linoleic acid components. Linseed oil is a golden-yellow, amber or brown liquid that is classified as a drying oil because it thickens and hardens on exposure to air (see also OILS, FATS AND WAXES). It has a low melting point (about -20° C.) and is a little more viscous than most vegetable oils. It is used in the manufacture of paints, printing inks, linoleum, varnish and oilcloth.

Linseed oil is prepared commercially in several grades, including raw, refined, boiled and blown. Raw oil is the slowest drying

of all the grades. The refined grade is raw oil from which solid fats, fragments of seeds and other undesirable materials have been removed. Boiled linseed oil dries in less time than either raw or refined oil and exhibits improved drying qualities (*i.e.*, it becomes thicker, denser and darker when dry) as a result of having materials called driers, such as manganese oxide, added while the oil is hot; the name is inaccurate, since the oil is not boiled. The blown grade dries to an even harder film as a result of having air blown through the oil while it is heated to about 125° C.; this grade is used in enamels and interior paints.

Although exposure to air causes the flavour of the seed to deteriorate rapidly, especially if it has been refined and deodorized, linseed was used as food by the ancient Greeks and Romans, and it continues to be used as such in parts of central Europe. In modern times, however, its main food use is as a livestock feed. After the oil is removed from linseed by compression, the remaining meal is heated and pressed into cakes for livestock. Linseed meal contains about 33% protein and is high in minerals, especially calcium and phosphorus. *See FEEDS, ANIMAL: Important Concentrate Feeds*; *see also references under "Linseed and Linseed Oil" in the Index.*

See U.S. Tariff Commission, Flaxseed and Linseed Oil, "Industrial Material Series" Report no. M-7 (Nov. 1952); E. W. Eckey, Vegetable Fats and Oils (1954). (P. Hx.)

LINTH, a river of Switzerland, is one of the tributaries of the Aare (*q.v.*). It rises in the glaciers of the Tödi range and has eroded a deep bed that forms the Linthtal, which comprises the greater part of the canton of Glarus. A little below the town of Glarus the river, keeping its northerly direction, flows across the alluvial plain that it has formed toward the lake of Zürich. In order to regulate the flow of the river over this plain it has been canalized, and dikes protect the riparian lands. These works were begun in 1807, and the first portion of the undertaking was completed in 1811, when it received the name of the Escher canal, the river being thus diverted into the Walensee or lake of Walenstadt. The Walensee is 9 mi. long with an area of 9 sq.mi., an altitude of 1,375 ft. and a maximum depth of 492 ft. The Churfirsten range dominates the northern shore, which is less populated than the southern. The Seer river enters the lake from the east. Wallenstadt is the main town on the lake. The second portion of the Linth, known as the Linth canal, regulated the course of the river between the Walensee and the lake of Zürich and was completed in 1816. Many improvements and extra protective works were carried out after 1816, the date of the completion of the work being 1911. The Linth emerges from the lake of Zürich as the Limmat and, keeping the northwesterly direction, joins the Aare a little way below Brugg and just below the junction of the Reuss with the Aare. The combined length of the Linth-Limmat is 87 mi. (A. F. A. M.)

LINTON, RALPH (1893-1953), U.S. anthropologist, an influential contributor to the development of cultural anthropology, was born into a Quaker family in Philadelphia, Pa., on Feb. 27, 1893. While a student at Swarthmore college (B.A., 1915), he participated in archaeological expeditions to New Mexico, Colorado and Guatemala. Thereafter, he studied at the University of Pennsylvania (M.A., 1916). After serving in the American expeditionary forces as a corporal during World War I, Linton studied briefly at Columbia university and then at Harvard university (Ph.D., 1925). During these student years he continued to engage in archaeological research in New Mexico, Colorado, Ohio and the Marquesas Islands. Linton's experience in the Marquesas Islands turned his attention to ethnology and, during his association with the Field Museum of Natural History (later the Chicago Natural History museum) from 1922 to 1928, he led an expedition to Madagascar (1926) that resulted in his major ethnographic work, *The Tanala, a Hill Tribe of Madagascar* (1933).

Linton was professor at the University of Wisconsin (1928-37), Columbia (1937-46) and Yale (1946-53). His most important theoretical work, *The Study of Man* (1936), was a widely influential synthesis of theories from anthropology, psychology and sociology concerning the nature of human culture. Other major works were *The Cultural Background of Personality*

(1945); and *The Tree of Culture* (1955), the fruition of his stimulating lectures on world ethnology at Yale university. His professional honours included the presidency of the American Anthropological association (1946), membership in the National Academy of Sciences, Viking fund medal (1952) and the Huxley memorial medal of the Royal Anthropological institute (1954). He died on Dec. 24, 1953, in New Haven, Conn. (D. B. Str.)

LINTON, WILLIAM JAMES (1812-1898), English wood engraver, author and active Chartist, was born in London on Dec. 7, 1812. He was apprenticed to the engraver, G. W. Bonner, and from an early age contributed engravings to the Royal Academy summer exhibitions and to books and periodicals, working both from his own designs and from those of other artists. He was noted for his skilful exploitation of the "white line." An ardent republican, Linton was politically active in the 1840s and early 1850s, founding a political party and editing a number of radical papers. His second wife, whom he married in 1858, was Eliza Lynn, the novelist, but the marriage was not a success. In 1866 Linton emigrated with his family to the United States. He set up a printing press at New Haven, Conn., where he died on Jan. 1, 1898. Linton wrote poetry, an autobiography (*Memories*, 1895) and books on his craft, among them *The Masters of Wood-Engraving* (1890). (A. Bs.)

LINUM, a genus of plants of the flax family (Linaceae). Of the approximately 200 species of *Linum* found in temperate and subtropical regions, especially the Mediterranean, about 35 are native to North America. Among these are *Linum virginianum* (slender yellow flax), of the eastern states; *L. floridanum* (Florida yellow flax), of the southeastern states; *L. rigidum* (large-flowered yellow flax), of the interior prairie region; *L. lewisii* (wild blue flax), widely distributed from Ontario to Alaska and southward to California and northern Mexico; and *L. californicum* (white-flowered flax), of the coast ranges.

L. grandiflorum (flowering flax), a native of north Africa, with large red flowers, and *L. flavum*, with golden-yellow flowers native to Europe, are grown as ornamental plants.

There are four species common in the British Isles and western Europe: *L. catharticum* (purging flax), with white flowers; *L. anglicum* (perennial flax); *L. bienne* (narrow-leaved flax); and *L. usitatissimum* (cultivated flax). Flax, the fibre from the stems of the last-named species, is used to produce linen yarn and fabric; the shorter fibres form tow. The seeds yield linseed oil and a meal used as cattle food. *See FLAX; LINEN MANUFACTURE; LINSEED AND LINSEED OIL.*

LINUS, SAINT was, according to Irenaeus, the immediate successor of St. Peter as bishop of Rome. Irenaeus says (in *Against Heresies*) "the blessed Apostles passed on the sacred ministry of the episcopacy to Linus." Linus was in all probability also attested by Hegesippus' list and is mentioned by Eusebius of Caesarea (*Church History*). In the *Book of Popes (Liber Pontificalis, Duchesne edition)* Linus comes immediately after St. Peter. This list dates back to primitive Christianity. His feast day is Sept. 23.

See L. R. Loomis and J. T. Shotwell, Book of the Popes, Eng. trans. based on Duchesne's work, in "Record of Civilization Series" (1916). (J. M. F. M.)

LINUS (Gr. LINOS), a name abstracted from the ancient ritual cry *ailinos*, the refrain of a dirge. It is at least as old as Homer (*Iliad*, xviii, 570). To account for this lament for Linus, as it was supposed to be, two principal stories were told:

1. According to the Argive story, Linus, child of Apollo and Psamathe, was exposed at birth and was torn in pieces by dogs. In revenge, Apollo sent a *Poine* or avenging spirit, which destroyed the Argive children. The hero Coroebus killed her, and a festival, Arnis, otherwise called Dog-killing day (*kunophontis*), was instituted, in which stray dogs were killed, sacrifice made, and Linus and Psamathe mourned for.

2. In the Theban version, Linus was the son of Urania and Amphimarus, and was a great musician. He invented the Linus song, but was put to death by Apollo for setting up as his rival. A later, half-burlesque story says that he was Hercules' music master, and was killed by his pupil, whom he tried to correct. He

had a cult on Mt. Helicon. Later tradition rationalized him into an ancient poet, prophet or the like.

This and similar figures (Adonis, Maneros, Narcissus) are plausibly explained as originating ultimately in the ceremonial lament for the dead corn spirit.

See Greve in Roscher's *Lexikon* (bibl.); J. G. Frazer, *Golden Bough*, vii, 257.

LINZ, the provincial capital of Oberösterreich (Upper Austria), lies on the Danube 100 mi. W. of Vienna. Pop. (1961) 195,978. The see of a bishop since 1785, it is a cultural centre with schools of art and music, a technical college, a religious seminary, scientific institutes, museums and art galleries, libraries, archives, an opera and theatres. Historic buildings include the castle; the Romanesque church of St. Martin (first mentioned 799); the early baroque town hall; the rectangular architecturally homogeneous main square (13th century) with a monument to the Holy Trinity; the City Parish church (built in the 13th century, remodeled baroque in the 17th century); the old cathedral (late 17th century); and the church of the Minorites (Franciscans) (13th century, remodeled 18th century). Other notable buildings are the 16th-century Landhaus (building of the provincial diet) and monastic churches (Capuchin, Ursuline, Carmelite). In the 19th century Archduke Maximilian d'Este fortified the town with a belt of towers, and the main fort on the Pöstlingberg (1,765 ft.) can be reached by mountain railway (one of the steepest without rack and pinion in Europe).

The most direct rail route between the Baltic sea and the Adriatic runs through Linz, and the town's position on the Danube makes possible a flourishing river transit trade. Urfahr, a large suburb on the left bank, is connected with the city by two bridges. After 1938 Linz developed into an important industrial centre with blast furnaces, smelting works, steel factories and a nitrogen fixation plant. War damage necessitated their reconstruction after 1945. The Linz-Donawitz (LD) oxygen-injection steel process is well known. The manufacture of machinery, electrical equipment, textiles and tobacco is also considerable.

Linz grew out of the Roman castle of Lentia (1st century A.D.) and it became an important medieval trading centre. By the 13th century it had all the outward characteristics of a regular city, but no civic rights. It achieved the status of provincial capital during the residence of the emperor Frederick III and was noted for its fairs. By the 18th century it was a city of the nobility, but it temporarily declined in the 19th century. The astronomer Johannes Kepler, the poet Adalbert Stifter and the composer Anton Bruckner all spent part of their working lives in Linz.

(W. F. RA.)

LION, since the earliest times one of the best-known wild animals, the proverbial "king of beasts." During the Pleistocene period the lion (*Panthera leo*) was distributed over the greater part of Europe, and within the historical period it inhabited north Africa, western Asia and probably Greece. It is now found in most parts of Africa south of the Sahara desert and in Kathiawar in Gujarat state, northwestern India, but is extinct in Iran and Iraq. The lion, tiger, leopard, jaguar, and snow and clouded leopards, generally known as the big cats, make up the genus *Panthera* of the family Felidae, order Carnivora (see CARNIVORE).

The lion is a powerfully built beast of prey with long body, short legs and large, well-developed muscles. It varies considerably in size but averages about 9 ft. 6 in. (including the tail), stands about 3 ft. at the shoulder and weighs 400 to 500 lb. The hair is short and varies greatly in colour from pale sandy to dark tawny; the tuft at the end of the tail is usually darker. The outstanding characteristic of the male, the mane, varies greatly in its development from the entirely maneless condition through a mere fringe of longer hair around the face to the splendid full mane. At its most luxuriant it covers the back of the head, neck and shoulders and is continued on to the throat and chest, where it joins a fringe along the underside of the belly. In some lions the whole of the mane and fringe are very dark, almost black, so that the animal has a majestic and impressive appearance; in others it is lighter, often no darker than the rest of the coat. The reasons for the variation in mane development are unknown; they

H. ARMSTRONG ROBERTS

FEMALE AND MALE LIONS (*PANTHERA LEO*)

may be heritable, like the differences in hairiness among human beings. But it has also been suggested that lions living in dense bush country have their manes so thoroughly combed while penetrating among thick thorn scrub that most of the long hair is pulled out. The fact that lions in captivity generally grow much longer and fuller manes than wild lions is quoted in support of this supposition. A newborn lion cub is covered with dark spots on a pale ground colour, but these markings are generally lost with approaching maturity; in some lions, however, the spots are retained on the limbs, under parts and flanks throughout life.

The lion has no definite breeding season, and cubs may be born at any time of the year; the litter varies from two to four, rarely six (in captivity). In captivity lions often breed every year, but in the wild it is probable that they do not breed more frequently than once in two years. In confinement lions and tigers occasionally interbreed (see TIGER). The young are born blind, the eyes opening at the age of about a week; they do not become adult until the permanent canines replace the milk teeth, at the age of about one year. In the wild the lion reaches its prime at about five or six years of age. The life span is not known for lions in the wild, but in captivity they may live 25 years or more.

The well-known roar of the lion is generally given forth when the animals arouse themselves in the evening before a night's hunting and again before lying up at dawn. The old story that the lion lashes himself into fury with the "claw" on his tail before making an attack is only a legend; the claw is usually no more than a small horny scale or spur attached to the skin at the tip of the last vertebra. In addition to the roar, the lion utters many other sounds: coughs, grunts, growls and deep purring noises.

Lions tend to be sociable animals and often live together in parties of a dozen or more, generally comprising several lionesses with their partly grown cubs. A lioness with cubs is often accompanied by a cubless lioness. The lion hunts by night and spends the day lying up in cover or under the shade of trees or rocks. After patiently stalking its prey, the lion makes a lightning-fast charge for the kill. Lions have frequently been seen hunting in company, and it is stated that some will lie in ambush while others of the party drive prey toward them. In Africa lions feed on any animals they can pull down, from the smaller antelopes to the giraffe, although it takes several working together to overcome the larger animals. In the neighbourhood of human settlements lions are sometimes very destructive to stock, showing great cunning in breaking into enclosures and enormous strength in jumping over thick fences with their prey in their jaws.

Lions, like most other potentially dangerous animals, generally avoid man, but they sometimes take to man-eating and may kill large numbers of natives if they are not promptly sought out and killed before man-eating becomes a habit. When brought to bay a lion will often charge his attacker, rushing upon him with great

speed. The lion can inhabit open country with only sparse cover.

LION FISH (TURKEY FISH), a tropical marine fish (*Pterois volitans*), somewhat poisonous, of very striking appearance: its very high dorsal and large pectoral fins are more or less divided into long, wide-spreading strands that stand out from the body. In each strand is a spine and an associated venom gland. Its body,

BY COURTESY OF NEW YORK ZOOLOGICAL SOCIETY

LION FISH (PTEROIS VOLITANS)

up to one foot long, and its fins are patterned with light and dark stripes.

Like the rest of the scorpion fish or rockfish family (Scorpaenidae), the lion fish is sluggish, spending most of its time on the bottom. It is found in the Indian ocean and in the Pacific from the East Indies eastward to Polynesia. Contact with the spines results in a painful wound in man; however, the toxin is not so virulent as that of the related stonefish or poison fish. See also SCORPION FISH; FISH.

(J. T. N.; X.)

LIONNE, HUGUES DE (1611-1671), French diplomat and statesman responsible for foreign policy in the first decade of Louis XIV's personal rule, was born at Grenoble in Dauphiné on Oct. 11, 1611. The nephew of Abel Servien, who was employed on diplomatic business by the cardinal de Richelieu until 1636, Lionne early became acquainted with foreign affairs and attracted the notice of Jules Mazarin during a period in Rome from 1636 to 1641. Mazarin intended in 1641 to take him as his secretary to the projected peace congress at Münster, but eventually Lionne was sent instead on a mission to Rome and to Parma. Recalled to Paris when Mazarin became chief minister (1643), Lionne was one of the "underminers" left with the royal government during Mazarin's temporary exile in 1651 (see FRONDE). Subsequently he took part in negotiating the League of the Rhine to counteract the Habsburg power in Germany (1658) and the Franco-Spanish peace of the Pyrenees (1659). Louis XIV took him into the upper council as a minister of state in 1661 and caused him to buy the office of secretary of state for foreign affairs in 1663.

A zealous worker with an excellent knowledge of Europe, Lionne has been accused of encouraging the young king's taste for an active foreign policy. He followed the traditional line of antagonism to Spain, together with that of seeking allies in Italy, Switzerland, Savoy and Germany. He tried to strengthen the League of the Rhine by bringing Brandenburg into it (1665) and made a treaty with Trier, Cologne and Mainz (1667) before the War of Devolution. After the peace of Aix-la-Chapelle (1668), the isolation of the Dutch, whom Louis intended to attack next, was pre-

pared by the treaty of Dover with England and by negotiations to ensure the neutrality of Austria and to detach Sweden from the alliance of 1668 with England and Holland. Lionne, however, died in Paris on Sept. 1, 1671, before the conclusion of treaties with Austria and Sweden enabled Louis XIV to begin war in 1672 (see DUTCH WARS). Pauline Payen (1630-1704), whom Lionne had married in 1645, became notorious for her amours.

André, *Louis XIV et l'Europe* (1950); G. Zeller, *Les Temps modernes*, vol. iii of the *Histoire des relations internationales*, ed. by P. Renouvin (1955).

LIONS, GULF OF (GOLFE DU LION), lies off the Mediterranean coast of France extending from Cap Cerbère to Cap Croisette, south of Marseilles. The sea bed is a gently sloping shelf extending to the 650-ft. line; along its margins are submarine canyons which include the Vallée de Montpellier and Vallée de Nîmes. The mean sea-water temperature varies from 13° C. (55° F.) in winter to 22° C. (71° F.) in summer; salinity averages 37.7 parts per 1,000. The coast bordering the gulf is low lying and fringed by a number of étangs (lagoons). In the east the delta of the Rhône river projects southward into the gulf and discoloured water issuing from it can be seen several miles out to sea.

(A. H. W. R.)

LIOTARD, JEAN ÉTIENNE (1702-1789), Swiss painter noted for his pastel portraits, was born at Geneva. He began his studies under Gardelle and Petitot. He went to Paris about 1723, studying under J. B. Massé and F. le Moyne, on whose recommendation he was taken to Naples by the marquis Piusieux. In 1735 he was in Rome, painting the portraits of Pope Clement XII and several cardinals. Three years later he accompanied Lord Duncannon to Constantinople; from there he went to Vienna in 1743 to paint the portraits of Empress Maria Theresa and her family. His eccentric adoption of oriental costume secured him the nickname of "the Turkish painter." He visited England, where he painted the princess of Wales in 1753, and went to Holland in 1756, where, in the following year, he married Marie Fargues. Another visit to England followed in 1772, and in the next two years his name figures among the Royal Academy exhibitors. He returned to his native town in 1776 and died there in 1789.

Liotard was an artist of great versatility, and though his fame depends largely on his graceful and delicate pastel drawings, of which "La Liseuse," the "Chocolate Girl" and "La Belle Lyonnaise" at the Dresden gallery are delightful examples, he achieved distinction by his enamels, copperplate engravings and glass painting. He wrote *Treatise on the Art of Painting*, and was an expert collector of paintings by the old masters. A portrait of the artist is in the Uffizi gallery, Florence, Italy.

LIOUVILLE, JOSEPH (1809-1882), French mathematician known for his work in analysis, the theory of numbers and differential geometry, was born at St. Omer on March 24, 1809. He graduated in 1827 from the École Polytechnique where, in 1833, he became professor. At the early age of 30 he was elected to the Académie des Sciences (Paris), and presently was appointed professor at the Sorbonne and the Collège de France. He founded (1836) and edited the *Journal des Mathématiques Pures et Appliquées*, which did much to raise and maintain the standard of French mathematics throughout the 19th century.

Liouville was a boldly original mathematician. His works, never collected, comprise about 400 memoirs and notes, more than 200 on the theory of numbers alone. In 1832-33, he investigated criteria for the analytic character of integrals of algebraic functions. Liouville was the first, in 1844, to prove the existence of transcendental numbers, and he constructed an infinite class of such numbers. He worked also in differential equations and boundary-value problems. His methods in this department became of capital importance in 20th-century mathematical physics as well as in the theory of integral equations. In differential geometry, he contributed notably to the theories of applicability of surfaces and conformal transformations. The concept of geodesic curvature was introduced by Liouville. Nearly all of his work on the theory of numbers (1857-82) was published without indication of the means by which he had obtained his striking re-

sults, relating mostly to numerical functions, representation in quadratic forms and general formulas in parity functions. All have since been proved. In analysis, Liouville was the first to deduce the theory of doubly periodic functions from general theorems, including his own, in the theory of analytic functions of a complex variable. He died at Paris on Sept. 8, 1882.

(E. T. B.; O. Oe.)

LIPARI ISLANDS (ISOLE EOLIE; AEOLIAN ISLANDS), a group of volcanic islands located off the north shore of Sicily, in Messina province. They have a general "Y" shape, the base of the "Y" being the westernmost island, Alicudi, the northern tip being Stromboli and the southern tip being Vulcano. The other major islands are Lipari, Salina, Filicudi and Panarea. Their total land area is 44 sq.mi. and the population (1961) was 13,774. Seismic and volcanic activity has been known since ancient times, and the Greeks believed the islands to be the home of Aeolus, king of the winds, hence the alternate name of the group. There are fumaroles on Lipari and Panarea; Vulcano and Stromboli are active. Pumice is exported from the islands, and the principal agricultural product is heavy malmsey-type wine from Lipari. There is regular steamer service to Milazzo, Messina and Naples.

Excavations in the 20th century have established an uninterrupted archaeological record from the Neolithic period. Ceramics and artifacts have been found, while the volcanic obsidian of the islands has been detected as far as Crete. A feature of archaeological research was substantiation of the legend that Aeolus came from Magna Graecia along the coast of south Italy rather than Sicily. Lipari (pop. [1961] 10,858 [commune]) is the chief town, with the important Aeolian archaeological museum. Panarea has a Bronze Age village; Stromboli's spectacular volcano is a noted tourist attraction.

The Greeks established themselves in the islands in the 6th century B.C. Later there was a Carthaginian naval station, until the Romans took over in 252 B.C. In Roman days, as in the Fascist era, the islands served as a place of banishment for political prisoners. In medieval times they were conquered by the Saracens, who were expelled by the Normans in the 11th century. The islands frequently changed hands during the wars between the Angevins of Naples and the Sicilian kings in the 14th century. Alfonso V of Aragon annexed them to Naples, but Ferdinand II of Aragon finally united them to Sicily in the late 15th century.

(G. KH.)

LIPCHITZ, JACQUES (1891–), one of the early revolutionaries of modern sculpture because of his participation in Cubism (*q.v.*) and his development of a new language for sculpture that was not based upon anatomy or the outward form of the human body. Born in Druskieniki, Latvia, Aug. 22, 1891, Lipchitz studied and worked in Paris after 1909; by 1941, when he moved to New York, his international reputation was established. His new means of interpreting the human body esthetically and psychologically can be seen in "Man With a Guitar" (1915) and "Prodigal Son" (1931). In his "transparencies" of the 1920s Lipchitz was one of the first sculptors to introduce voids within his sculptured figures. His strongest art deals with tension, as in "Figure" (1926–30), and man's spiritual history, as in "The Virgin of Assy" (1948–54). Lipchitz always stressed the sculptor's transforming manipulation and shaping power.

There is a well-known portrait of Lipchitz and his wife by Amedeo Modigliani (*see* PORTRAIT PAINTING: *The 20th Century*).

See Henry R. Hope, *The Sculpture of Jacques Lipchitz* (1958); Robert Goldwater, *Lipchitz* (1959).

(A. E. EL.)

LIPETSK, a town and *oblast* centre of the Russian Soviet Federated Socialist Republic, U.S.S.R., stands on either bank of the Voronezh river, a tributary of the Don, where it is crossed by the railway from Orel to Borisoglebsk, 65 mi. N.N.E. of Voronezh city. Pop. (1959) 156,515. The town was founded in 1707 as an iron-working centre by Peter the Great to supply his Don fleet and armies in his Azov campaigns. By the end of the 18th century iron working had ceased, but it was begun again in 1877. There are two metallurgical plants where iron castings and drainage and water pipes are made, and a large tractor factory; radi-

tors, chemicals, foodstuffs and cement are also produced.

LIPETSK oblast, formed in 1954 out of parts of Voronezh, Orel, Ryazan and Kursk *oblasts*, covers 9,305 sq.mi. The western part consists of the rolling hills of the Central Russian upland (Sredne-Russkaya Vozvyshennost'), while the eastern part lies on the low Oka-Don plain. The Don and Voronezh cross the centre of the *oblast* from north to south. The *oblast* lies in the zone of forest-steppe. Soils are rich chernozems, so that much of the oak forest cover and almost all the grass steppe has been cleared and plowed up until 74% of the surface is now arable. This has resulted in severe gully erosion of the soil and loess subsoil, especially on the Central Russian upland. The climate is modified continental, with January average temperature about -10° C. (14° F.) and July averages about 20° C. (68° F.). Precipitation is about 18 in. a year, but tends to be variable.

The population of the *oblast* in the 1959 census was 1,141,522. Only 30% (344,680) were urban dwellers (*cf.* the national figure of 48%); nearly half lived in Lipetsk and a further 77,900 in Yelets. There are 8 towns and 3 urban districts. The large rural population reflects the dominance of agriculture. Leading crops are winter rye (a quarter of the arable), spring and winter wheat, maize (corn), oats, sugar beet and potatoes. Sunflowers and hemp are also important. Livestock numbers are low. There are extensive iron ore deposits in the *oblast*, part of the Kursk Magnetic Anomaly, and during the 1950s these began to be exploited. Apart from Lipetsk there are several small iron-founding centres, but industry in general is concerned with processing agricultural products.

(R. A. F.)

LIPIDS: *see* OILS, FATS AND WAXES.

LIPMANN, FRITZ ALBERT (1899–), U.S. biochemist, received (with H. A. Krebs) the 1953 Nobel prize for medicine and physiology for his discovery of coenzyme A, a vital catalyst in cellular metabolism. Born in Königsberg, Ger., on June 12, 1899, he studied medicine at the universities of Königsberg, Munich and Berlin (M.D., 1922) and later chemistry (Ph.D., Berlin, 1927). He did early research in cellular metabolism in the laboratory of Otto Meyerhof at Heidelberg (1927–30), and in 1931–32 he worked as a Rockefeller foundation fellow at the Rockefeller institute in New York city. After a short period with Albert Fischer at the Kaiser Wilhelm institute, Berlin, he followed him to Copenhagen, Den., to work on tissue cultures at the newly established Biological Institute of the Carlsberg foundation (1932–39). He joined the faculty of Cornell Medical school (New York city) in 1939 and became a U.S. citizen in 1944. He was head of the biochemical research department, Massachusetts General hospital, Boston (1941–57), and was professor of biological chemistry at Harvard Medical school from 1949 until 1957, when he returned to the Rockefeller institute. He reported the isolation of coenzyme A in 1947 and again in 1950, and announced (with co-operating workers) its structure in 1953.

(G. E. PN.)

LI PO (LI T'AI-PO) (701–762), Chinese poet, a rival of his contemporary Tu Fu (*q.v.*) for the title of China's greatest poet, was born in 701 in Szechwan, in the southwest of the empire. He liked to regard himself as belonging to the imperial family, but he in fact belonged to a less exalted though quite distinguished family of the same surname. At the age of 19 he left his home and lived with a Taoist recluse.

A period of wandering followed, after which he married and lived with his wife's family, north of Hankow. He had already begun to write poetry and showed some of it to various officials, in the hope of getting employed as a secretary, but had no success. In 734 he visited a friend at T'ai-yuan in northeast China. Another period of wandering followed, and in 742 he arrived at Ch'ang-an, the capital, no doubt hoping to be given a post at court. He did not, however, receive any official post but was merely accepted into a pool of distinguished poets, who were kept ready at any moment to celebrate the doings of the court in verse. But he disliked the atmosphere of intrigue by which he found himself surrounded, and in the autumn of 744 his wanderings recommenced. It was now that he met the other great poet of the period, Tu Fu (712–770), who was then hardly known, whereas

Li Po's fame was already immense. Tu Fu, it is clear, was completely carried away by the dash and verve of the older poet. Li Po was becoming increasingly wrapped up in Taoism and alchemy, and at about this time was definitely accepted as a Taoist initiate, receiving at the hands of a high Taoist dignitary a diploma of spiritual progress.

In the autumn of 756 Prince Lin, the emperor's 16th son, was given a big command in south China to fight against a rebellion. He was bringing troops down the Yangtze river in transports early in 757 and was halting at Chiu-chiang when he heard that the famous poet Li Po was living in the town. He asked him to come on board, and Li Po became a sort of unofficial poet laureate to the expedition. But shortly afterward the prince was accused of intending to set up an independent kingdom. He was captured by government troops and executed. Li Po was arrested and thrown into prison at Chiu-chiang. In the autumn a high official, ordered to review the sentences passed in connection with the recent troubles, looked into Li Po's case, released him and took him on to his staff as a secretary. However, in the summer of 758 the charge against him was revived, and he was banished to Yeh-lang, on the southwestern fringe of the empire. But before he got there, he benefited by a general amnesty (May 759). He came back to eastern China and died in the house of a relative, at Tang-t'u (about 60 mi. south of Nanking), in 762.

See Shigeyoshi Obata, *The Works of Li Po* (1923); A. Waley, *The Poetry and Career of Li Po*, 701-762 A.D. (1951). (A. D. WA.)

LIPPE, one of the smallest of the former member-states of the German *Reich*, with a territory of 469 sq.mi., and a population of 187,220 in 1939. It extended from the mountains overlooking the east-west bend of the middle Weser river southwestward across the Detmold hills to the Werre basin and then across the high ridge of the Teutoburg forest to the Senne moorland.

The noble lords of Lippe had their original possessions around Lippstadt (on the Lippe river west of Paderborn). From 1190, however, they began to build up a distinct territory to the north and northeast. The towns of Lemgo, Horn, Blomberg and Detmold, founded between 1200 and 1260, became the core of this territory, which until the beginning of the 15th century had expanded southeast over the countship of Schwalenberg and northward over that of Sternberg. Simon V of Lippe (d. 1536) assumed the title of count in 1528. Lutheranism was established in 1538, Calvinism in 1605. The sons of Simon VI (d. 1613) partitioned their inheritance, but from 1709 the senior line of the dynasty, Lippe-Detmold, began to reunite the hereditary possessions—though the line of Alverdisen, which in the 1640s had founded the separate house of Schaumburg-Lippe (q.v.), did not lose its last enclave within the Detmold zone until the end of 1838. The heads of Lippe-Detmold were princes from 1720.

Lippe obtained recognition as a sovereign state on entering the Confederation of the Rhine in 1807. A member of the German confederation from 1815, it took Prussia's side in the Seven Weeks' War (1866) and became a member of the North German confederation in 1867 and a federal state of the German empire in 1871. From 1866 it was completely surrounded by Prussian territory. When the senior branch of Lippe-Detmold died out in 1905, the head of the Lippe-Biesterfeld branch succeeded to the principality as Leopold IV. After Leopold's abdication (1918), the state had a democratic constitution under the republican regime until 1933. Under British military government from 1945, Lippe was merged on Jan. 21, 1947, with the *Land* (state) of North Rhine-Westphalia, from 1949 part of the Federal Republic of Germany.

See E. Kittel, *Geschichte des Landes Lippe* (1957). (FH. H.)

LIPPE RIVER, a right-bank tributary of the Rhine in the *Land* (state) of North Rhine-Westphalia, Federal Republic of Germany, rises near Bad Lippspringe under the western slope of the Teutoburger Wald and, after a course of 147 mi., flows into the Rhine near Wesel. It is navigable, by the aid of 12 locks, downstream from Lippstadt, for boats and barges drawing less than four feet. The Lippe was once used for the transport of coal, timber and agricultural produce to and from Westphalia, but in 1930 it was replaced by a canal that follows its course from the

Dortmund-Ems canal to the Rhine. The Lippe supplies water to the canal system of the Ruhr. The canal, which carries 6,000,000 tons of cargo annually, takes the largest barges that use the Dortmund-Ems canal. During the 1960s it was extended beyond the Dortmund-Ems canal toward Hamm. (R. E. DI.)

LIPPI, FILIPPINO (FILIPPO) (c. 1457-1504), Italian painter, son of Fra Filippo Lippi (q.v.) and the nun Lucrezia Buti, was a follower of his father and of Botticelli. He was born at Prato, probably in 1457. After Fra Filippo Lippi's death, Filippino entered the workshop of Botticelli. By 1473 he had finished his apprenticeship. The style of Filippino's earliest works stems from that of Botticelli; they include Madonnas at Budapest, Berlin and in the National gallery, London, where there is also an "Adoration of the Magi." Filippino's use of line throughout these panels is less sensitive and subtle than Botticelli's. In a group of paintings executed about 1480-85 he develops a harder and more individual style. The most notable of these are altarpieces in S. Michele at Lucca and the Museo di Capodimonte in Naples, and a panel of the "Journey of Tobias" in the Pinacoteca Sabauda, Turin. Despite the lack of dated or documented works, it is clear that by this time Filippino enjoyed a considerable reputation, since he is known to have been employed, along with Botticelli, Perugino and Ghirlandajo, on the frescoed decoration of Lorenzo de' Medici's villa at Spedaletto near Volterra, and at the end of 1482 was commissioned to complete work left unfinished by Perugino in the Palazzo della Signoria in Florence. No trace of either work survives. Soon after (probably 1483-84) he was entrusted with the completion of the frescoes in the Brancacci chapel in the Carmine, which had been left unfinished on Masaccio's death in 1428.

His most popular picture, the beautiful altarpiece of the "Virgin Appearing to St. Bernard" (Badia, Florence), has been variously assigned to the years 1480 and 1486. In April 1487 Filippino Lippi signed a contract for the frescoed decoration of the chapel of Filippo Strozzi in Sta. Maria Novella, Florence. Work on this was delayed by a second commission for a fresco cycle, this time in Rome, where, on the recommendation of Lorenzo de' Medici, Filippino was invited to decorate the Caraffa chapel in Sta. Maria sopra Minerva. Nothing in Filippino's earlier works prepares for the vein of inspiration which he struck in the Caraffa chapel, where the roof is filled with four figures of sibyls, the right wall with frescoes of the "Miracle of the Speaking Crucifix" and the "Triumph of St. Thomas," and the altar wall with a fresco of the "Assumption."

On his return from Rome (probably 1491) Filippino Lippi executed a fresco of the "Sacrifice of Laocoon" for the villa of Lorenzo de' Medici at Poggio a Cajano, in which some of the decorative expedients used in the Caraffa chapel are again employed, and resumed work in the Strozzi chapel (completed 1502), the frescoes of which look forward to the Tuscan Mannerism of the 16th century. Of the large number of panel paintings produced in this, Filippino's final phase, the most remarkable are an "Adoration of the Magi" in the Uffizi (painted for S. Donato a Scopeto in 1496) and an altarpiece of the "Deposition" commissioned for the high altar of SS. Annunziata in Florence and completed after Filippino's death by Perugino (Uffizi, Florence). Filippino died on April 18, 1504.

See A. Scharf, *Filippino Lippi* (1935); K. Neilson, *Filippino Lippi* (1938). (J. W. P.-H.)

LIPPI, FRA FILIPPO (LIPPO) (1406-1469), one of the best-known and most influential Tuscan painters of the 15th century, was born in Florence in 1406. His father, a butcher, died during Lippi's boyhood, and the boy was given over by his mother to the Carmelite friars of Sta. Maria del Carmine in Florence, where on June 18, 1421, he took his first vows. He is mentioned in 1430 as a painter in the community records, where his name appears in Jan. 1432 for the last time. Filippo Lippi was thus trained as a painter under the shadow of Masaccio's and Masolino's frescoes in the Brancacci chapel in the Carmine. These influences are reflected in what is probably his earliest work, a fresco formerly in the cloister (now transferred to canvas) commemorating the reform of the Carmelite order by Pope Eugenius

NATIONAL GALLERY OF ART, WASHINGTON, D.C., SAMUEL H. KRESS COLLECTION
 "MADONNA AND CHILD" BY FRA FILIPPO LIPPI. IN THE NATIONAL GALLERY OF ART, WASHINGTON

IV in Feb. 1432. In the massive forms of the figures in this fresco and in its solidly constructed architecture Lippi reveals his study of Masaccio, though a latent decorative tendency (later to dominate his work) is already evident in the delicate palette and light tonality. At this point Lippi appears to have left Florence, and in the summer of 1434 was employed in S. Antonio at Padua.

His first dated work, a "Madonna" from Tarquinia Corneto, now in the Galleria Nazionale in Rome, belongs to the year 1437. Like the Carmine fresco, the "Madonna" of 1437 is a powerful and uncompromising work. Immediately after it, Lippi seems to have executed what is perhaps his finest and most characteristic panel painting, an altarpiece of the Annunciation in S. Lorenzo in Florence. This combines space structure of great sophistication with the simple emotionalism that ensured him lifelong popularity. On March 8, 1437, Lippi received the commission for an altarpiece for the Barbadori chapel in S. Spirito (now in the Louvre, Paris). Between 1441 and 1447 Lippi painted for the high altar of S. Ambrogio the great altarpiece of the "Coronation of the Virgin," now in the Uffizi. This includes on the right a self-portrait of the painter designated by the words, *Is perfectit opus*.

After about 1445 Lippi seems to have fallen under the influence of Fra Angelico, which is manifest in the relatively simple scheme of a second altarpiece of the "Coronation of the Virgin" painted for the convent of Monte Oliveto at Arezzo after 1444 (Vatican gallery), as well as in a masterly *tondo* of the "Adoration of the Magi" now in the National gallery, Washington. A second circular painting of somewhat later date (probably 1452), showing the

Virgin and Child with scenes from the life of St. Anne in the background, exists in the Palazzo Pitti, Florence; in this too the problem of the circular field is solved with consummate mastery. Thereafter Lippi began work on his most ambitious project, the frescoed decoration of the choir of the cathedral at Prato illustrating the life of St. Stephen and that of St. John the Baptist. The commission for these important frescoes was first offered to Fra Angelico and subsequently (1452) to Fra Filippo Lippi. Work on them appears to have continued until 1464. The bottom frescoes on each side of the choir are works of great solemnity and power. In 1466 Lippi commenced his last major work, the frescoes in the apse of the cathedral at Spoleto. Owing to the master's ill health these weak works were executed almost exclusively by members of his studio.

While in Prato Fra Filippo Lippi abducted from the convent of Sta. Margherita (of which he was chaplain) a nun, Lucrezia Buti, who became the mother of the painter Filippino Lippi (q.v.) and who, according to Vasari, was depicted by Lippi in certain paintings.

Lippi died at Spoleto on Oct. 9, 1469.

See R. Oertel, *Fra Filippo Lippi* (1942).

(J. W. P.-H.)

LIPPMANN, GABRIEL (1845–1921), French physicist, invented the photographic reproduction of colour by what is known as the Lippmann interference process, for which he was awarded the 1908 Nobel prize for physics. He was born on Aug. 16, 1845, at Hollerich in Luxembourg of French parents, who soon after his birth settled in Paris. He was educated at the École normale and the universities of Heidelberg and Berlin, becoming a member of the faculty of sciences in Paris in 1878. The whole of his life was devoted to teaching and research. In 1883 he was appointed professor of physics and was subsequently director of the laboratory for physical research at the Sorbonne, and in the same year he was elected a member of the Paris Academy of Sciences. Of an original and independent mind, he made important contributions to many departments of physics, but especially to electricity, thermodynamics, optics and photochemistry. One of his earliest achievements was the construction of a capillary electrometer of extraordinary sensitivity. The principle of the Lippmann colour process was communicated to the Academy of Sciences in 1891, but it was not until 1908 that he was awarded the Nobel prize for physics for this work. He was president of the Academy of Sciences in 1912, and he was a foreign member of the Royal society of London. He died at sea on July 13, 1921, while returning from a visit to Canada. See PHOTOGRAPHY: *Colour Photography*. (W. J. BP.; X.)

LIPPMANN, WALTER (1889–), U.S. newspaper commentator and author of numerous books on public affairs, was born in New York city, Sept. 23, 1889. He graduated from Harvard in 1910. In writing on public events for more than 50 years thereafter, Lippmann made himself the foremost commentator in the United States and won a world-wide reputation. From the publication of his first book, *A Preface to Politics*, in 1913, it was evident that he had a discerning grasp of political trends at home and abroad, with a capacity to see where these trends were leading. After a brief apprenticeship with Lincoln Steffens on *Everybody's Magazine* and a briefer excursion into practical politics with the Socialist mayor of Schenectady, N.Y., he became one of the founders and associate editor of the *New Republic*. He was one of the brilliant young men who exerted a great influence on Woodrow Wilson, both through the pages of that liberal weekly and in direct consultation with the president. It was at Wilson's request that after wartime service with the U.S. military intelligence Lippmann served as an aide to Col. Edward M. House in Paris and contributed substantially to Wilson's fourteen points and to the concept of the League of Nations. Deeply disillusioned with the outcome of the Versailles conference, Lippmann returned to the U.S. and became editor of the *New York World*. When the *World* was sold, he began to write for the *New York Herald Tribune* an independent commentary that was syndicated to a large number of newspapers at home and abroad. He was twice honoured with the Pulitzer prize, in 1958 and 1962, for his newspaper articles. Among more than a score of published books, his most influential

works have been *Public Opinion* (1927), *A Preface to Morals* (1929) and *The Good Society* (1937). *Essays in the Public Philosophy* (1955) was criticized in some quarters because of its espousal of the concept of natural law as paramount. After 1938 Lippmann lived in Washington, D.C., with his wife, the former Helen Byrne Armstrong. In writing his commentary he traveled widely in the U.S. and in Europe, Asia and Latin America.

See M. W. Childs and J. B. Reston (eds.), *Walter Lippmann and His Times* (1959); Clinton L. Rossiter and J. Lare, *The Essential Lippmann: a Political Philosophy for Liberal Democracy* (1963). (M. W. CH.)

LIPPS, THEODOR (1851–1914), German psychologist and philosopher, was born July 28, 1851, at Wallhalben, and was professor successively at Bonn, Breslau (now Wrocław) and Munich. His fundamental principles assumed a dependence of consciousness upon the interaction between older experiences retained in a subconscious state and the entering sensations (apperception). Mind, he said, is the sum of these older experiences organized in a unity. The organization controls the course of perceiving, of recall and thinking and of action. Pleasure is harmonious interaction of the old upon the new; displeasure results from conflict of the different elements.

The best-known phase of his theory is his doctrine of *Einfühlung*, defined as projecting one's self into what is seen. One appreciates another's reaction by feeling one's self into the other. In his two-volume *Ästhetik* (1903–06) Lipps makes all artistic appreciation depend upon a similar self-projection into the object. Part of feeling is dependent upon definite induced bodily responses like imitation. A form is beautiful that is obviously adequate to a situation. A lithe but not emaciated human figure is beautiful. A column that is too slight apparently to support a weight put upon it arouses sympathy; it makes the observer strain unduly and so is unpleasant. In an experimental study of optical illusions (*Raum-ästhetik*, 1897) Lipps suggests that a vertical line is apparently longer than a horizontal one because it induces the observer to stretch up and the movement is assigned to the line. His publications include, in addition to those mentioned, *Grundtatsachen des Seelenlebens* (1883), *Die ethischen Grundfragen, zehn Vorträge*, 2nd ed. (1905), and *Leitfaden der Psychologie*, 3rd ed. (1926). Lipps died at Munich on Oct. 17, 1914. (W. B. PR.)

LIPPSTADT, a town of Germany, which after partition of the nation following World War II was located in the *Land* (state) of North Rhine-Westphalia, Federal Republic of Germany. It is situated on the Lippe, 32 km. (20 mi.) W. of Paderborn by road. Pop. (1961) 37,502. Lying on the slopes of the Teutoburger Wald, Lippstadt is a picturesque town with 12th- and 13th-century churches. The Hotel Köppelmann has a fine rococo hall. There are many fine old half-timbered houses. The moated castles of Overhagen, Eringerfeld, Heringhausen and Körtinghausen are nearby. Lippstadt is a junction on the railway from the Ruhr to Paderborn and Hanover. The town was founded in 1168 by the lords of Lippe and joined the Hanseatic league in the 13th century. The rights over one-half of the town passed to the counts of the Mark, which in 1614 was incorporated with Brandenburg; in 1850 the prince of Lippe-Detmold sold his share to Prussia.

LIP-READING: see DEAF AND HARD OF HEARING, TRAINING AND WELFARE OF.

LIPSIUS, JUSTUS (JOEST LIPS) (1547–1606), Belgian humanist, classical scholar and moral and political theorist, was born at Overijse near Brussels on Oct. 18, 1547. Brought up as a Roman Catholic, he attended the Jesuit college at Cologne and the University of Louvain. Like many savants of his period he lived much abroad. Unsettled political conditions made him leave Belgium in 1571, and about a year later, when he was appointed to the chair of history and philosophy at Jena, he furnished some proof of Protestant convictions. This made him suspect when he returned to his country. He decided to withdraw again and in 1578 accepted the chair of history and law at the new university of Leiden. In 1591, however, he was reconciled to the Catholic Church. He was appointed professor of history and Latin at Louvain (1592). At Leiden he was soon succeeded by J. J.

Scaliger (q.v.), whose Calvinistic allegiance remained unchanged. Thus Lipsius' Louvain and Scaliger's Leiden became, for a time, rival centres of humane learning. Lipsius died at Louvain on March 23/24, 1606.

Lipsius' first scholarly publication, the *Variae lectiones* of 1569, was in the traditional field of textual criticism. He quickly established himself as the leading editor of Latin prose texts, and his editions of *Tacitus* (first in 1574) and of *Seneca* (1605) were long renowned as models of their kind and are still worthy of attention. Many of his emendations survive in modern editions. Lipsius, too, was a leader in the anti-Ciceronian, stylistic movements of his time. His Latin writing, terse and epigrammatic, owes a large debt to Tacitus. Force of personality and style also distinguish his vast correspondence conducted in the Latin language.

Moreover Lipsius was noted for his antiquarian and historical studies and still more for his essays in moral and political theory. His introduction to Stoic thought of 1604 (for which again Seneca provided the foundation) remained the most intelligent and complete assessment of that philosophy for more than two centuries although it was chiefly Roman, not Greek, Stoicism that inspired it. For him the ancient philosophers and historians were, however, no mere subjects for research: they were guides to practical morality. He considered himself a Stoic, and his interest in Seneca lies at the root of his tract *De constantia* (1584). Similarly, his interest in Tacitus inspired his political theory, the *Politicorum libri sex* of 1589. But it was a Tacitus seen through the Machiavellian spectacles of the time, and it gave rise to the curious, neo-Tacitean doctrine of politics—a characteristic feature of the following 17th century.

BIBLIOGRAPHY.—For a list of Lipsius' publications see F. van der Haeghen, *Bibliographie Lipsienne*, 3 vol. (1886–88); for his textual criticism see C. O. Brink in *Journal of Roman Studies*, vol. 41 (1951). See also H. F. Bouchery, *Waarom Justus Lipsius gevierd?* (1949); J. L. Saunders, *Justus Lipsius: the Philosophy of Renaissance Stoicism* (1955); G. Toffanin, *Machiavelli e il Tacitismo* (1921); A. Momigliano, "The First Political Commentary on Tacitus," *Journal of Roman Studies*, vol. 37 (1947). (C. O. BR.)

LIPSIUS, RICHARD ADELBERT (1830–1892), German Protestant theologian, was born at Gera on Feb. 14, 1830. He studied at Leipzig and eventually (1871) settled at Jena as professor of systematic theology. He helped found the Evangelical Protestant Missionary union and the Evangelical alliance and from 1874 took an active part in their management. He died at Jena on Aug. 19, 1892.

Lipsius wrote principally on dogmatics and the history of early Christianity from a liberal standpoint. His chief works are *Philosophie und Religion* (1885) and *Lehrbuch der evangelisch-protestantischen Dogmatik* (1876), in which his systematic doctrines are described. His other works include *Die apokryphen Apostelgeschichten und Apostellegenden*, four volumes (1883–90), dealing with problems in early Christian apocryphal literature; studies in the early history of the papacy; and commentaries on the Epistles to the Galatians, Romans and Philipians.

See A. Neumann, *Grundlagen und Grundsätze der Weltanschauung von R. A. Lipsius* (1896).

LIPTON, SIR THOMAS JOHNSTONE, 1ST BART. (1850–1931), British merchant and yachtsman, equally well known for his success with tea and for the gallant sportsmanship with which he accepted his failures in international yachting, was born at Glasgow, Scot., on May 10, 1850, of Irish parents, who ran a small grocer's shop. He emigrated to the United States in 1865 and held various jobs for five years before returning to Glasgow.

There he opened a small provision shop, was very successful and established shops throughout the United Kingdom. To supply his retail shops on the most favourable terms, he purchased extensive tea, coffee and cocoa plantations in Ceylon and provided his own packing house for hogs in Chicago. He also acquired fruit farms, jam factories, bakeries and bacon-curing establishments in England. In 1898 his business was organized into Lipton, Ltd. He was knighted in 1898 and created a baronet in 1902, taking as his crest two arms holding sprigs of tea and coffee.

He was a keen yachtsman and as a representative of the Royal

Ulster Yacht club made five unsuccessful attempts between 1899 and 1930 to win the America's cup with yachts called "Shamrock" (see YACHTING). Lipton won a reputation for being the "world's best loser," and in 1930 he was presented with a gold cup for sportsmanship by a group of Americans. He died in London on Oct. 2, 1931.

See Alec Waugh, *Lipton Story* (1950).

LIQUEFACTION OF GASES: see LOW-TEMPERATURE PHYSICS; REFRIGERATION.

LIQUEURS. A liqueur (from the Latin *liquefacere*, "to make liquid") is a spirit which has been sweetened and flavoured with fruit or herbs. The alcoholic content of a liqueur, which is usually high, as well as the medical herbs which it frequently contains, are both agents which have been recognized as curative and digestive since the middle ages. Liqueurs are also often used as a liquid centre for chocolates.

There are three kinds of liqueur: those with one herb predominating in their flavour; those with only one fruit; and those with a mixture of flavouring agents. Kümmel, made from caraway or cumin seeds, and framboise, made from raspberries, are good examples of the first two types, while Bénédictine is made of about 30 different herbs and other ingredients.

There are two main methods of making liqueurs. The first is by distilling all the ingredients together, the resulting distillate being sweetened and sometimes coloured. The second is to add an infusion of herbs, or fruits, to the base spirit; this is the method generally followed as it preserves the freshness, colour and bouquet of the ingredients. The best liqueurs are usually made upon a Cognac base.

It is easy to confuse liqueurs with spirits or with bitters (*q.v.*). When a liqueur is made upon a brandy or gin base it may be sold as a brandy or a gin, such as cherry brandy or sloe gin—but these are liqueurs, since they are sweetened. An unsweetened spirit cannot be called a liqueur; there is, for instance, a genuine unsweetened Hungarian and Yugoslavian brandy called Slivovitz, distilled from plums. Confusion may be deepened when the same name is used for both liqueurs and brandies; there is a sweet apricot brandy—a liqueur—as well as an unsweetened spirit made from apricots, and also known as apricot brandy. While sloe gin is a liqueur, lemon and orange gin are ordinary dry gins, with fruit added for flavouring. Although combined spirits are sometimes referred to as liqueurs, they should not be unless sweetened. Similarly, "liqueur brandy" is a misnomer; the word liqueur only refers here to its use as a *digestif* or to its specially good quality. Bitters can be used as *digestifs* but they are usually *apéritifs*. They differ from liqueurs in that they are only very slightly sweetened, if at all.

The making of liqueurs was practised from earliest times. The writings attributed to Hippocrates say that the ancients distilled herbs and plants, and because certain herbs were noticed to cure illness or to be effective as tonics, liqueur-making had a close association with early medicine and with medieval astrology. The Saxon word "wort" means a plant used for medicine. Certain plants were believed to keep away evil spirits, sometimes if they were merely pinned to a door. The remedies were certainly effective when they were administered; aniseed, caraway seed and mint, for instance, were long known to help digestion. Nicholas Culpepper, a 17th-century writer on medicine, advises "a water distilled from (angelica) root" for the same purpose; angelica is frequently used in liqueurs, together with many other herbs, such as coriander, fennel, wormwood, gentian, amber, hyssop and thyme.

A particular area of the world will often produce a variety of herb or fruit which is best for liqueur-making, and it is there that the industry will be situated. For example, the small apricot that is found in the Île-de-France is the only one that will make abricotine, and the wild blackthorn of Devon and Cornwall makes the best sloe gin. The fruit must always be picked at its ripest, and even slightly blemished fruit discarded.

(C. C. H. F.)

LIQUIDAMBAR, a genus of four species of deciduous trees of the witch hazel family (Hamamelidaceae). *Liquidambar styraciflua* (sweet gum; *q.v.*), is North American, the others are Asiatic: *L. orientalis*, of Asia Minor; *L. formosana*, of southern China, Formosa and Indochina; and *L. edentata*, of southeast China. These species yield useful timber and a resin, storax. The leaves are often almost star-shaped, being palmately cut into three to seven lobes, and the flowers are usually unisexual and without petals. The male flowers, each with numerous stamens, are grouped into clusters that terminate the branches; the female flowers, each consisting of a two-celled ovary with two long styles, are in long-stalked solitary heads. The fruit, which consists of many capsules united, is a spiny ball. Several fossil species of *Liquidambar* are known.

(J. W. Tr.)

LIQUIDATION, a term often used to denote the discharge of a debt or the ascertainment by agreement or litigation of the amount of a previously unliquidated claim. An important specialized legal meaning is the distribution of the assets of an enterprise among its creditors and proprietors. Solvent corporations or unincorporated associations are sometimes wound up. More often than not the assets are liquidated (turned into money) in preference to attempting distribution of the assets in kind. The liquidation of insolvent concerns may take place in receiverships, under general assignments for the benefit of creditors, in bankruptcy, or in the administration of decedents' estates. See BANKRUPTCY; COMPANY: *Company Law*; CORPORATION: *Corporation Law*; DEBTOR AND CREDITOR LAW; RECEIVER.

(J. A. MacL.)

LIQUID STATE. The states of aggregation of substances are commonly classified as gas, liquid and solid (see PHASE EQUILIBRIA). Elastic solids resist both tensile and shear deformation with stresses proportional to the strains and are therefore capable of supporting shearing stresses at equilibrium. Gases and liquids resist shear deformation only with a stress proportional to the rate of strain and are therefore incapable of supporting shearing stresses at equilibrium. Thus gases and liquids are distinguished from solids by the property of fluidity; *i.e.*, under the action of external forces they flow and adapt their shapes to those of their containers. The mechanical distinction between fluids and solids is not sharp. Numerous substances can be maintained in a metastable state, the glassy state, with mechanical properties intermediate between those of the elastic solid and the viscous fluid. These noncrystalline solids are often unstable with respect to transformation to crystalline phases, but the rate of transformation may be extraordinarily small.

Macroscopic Properties of Liquids at Equilibrium.—As a rule, substances possess only one liquid modification. Exceptions are found in the case of: (1) helium with isotopic mass 4, which possesses two liquid forms; (2) substances that possess optically and mechanically anisotropic liquid crystalline phases as well as a normal liquid phase (*e.g.*, para-azoxyanisole); and (3) substances that can be isolated in pure quantum states (orthohydrogen and parahydrogen).

In general, substances possess one or more crystalline solid phases, some or all of which may be capable of coexistence with the liquid phase. For a one-component system, the conditions under which phases can coexist in contact under conditions of equilibrium are described by a relation between the number of degrees of freedom, *f*, and the number of phases, *ν*. Provided (1) that the only external force is a uniform normal pressure, (2) that interphase boundaries are deformable, permeable to all components and heat conducting, and (3) that surface effects are negligible, then $f = 3 - \nu$. The liquid and solid phases can coexist along a continuous locus of temperature and pressure ($\nu = 2$, $f = 1$) but the liquid, solid and gaseous phases can coexist at only one temperature and pressure ($\nu = 3$, $f = 0$). There is experimental evidence that equilibrium between solid and liquid is possible at all temperatures so long as decomposition or ionization does not occur. In contrast, the equilibrium locus between the liquid and gaseous states ($\nu = 2$, $f = 1$) terminates at a critical point. At each temperature below the critical temperature, T_c , there exists a pressure (the vapour pressure) at which the (more dense) liquid phase and the (less dense) vapour phase coexist.

Above the critical temperature there is no distinction between gas and liquid and there exists but a single fluid phase.

The transition from the liquid phase to the gaseous phase occurs discontinuously at that temperature for which the vapour pressure equals the external pressure. The transformation requires the absorption of a quantity of heat per unit mass, L_v , the latent heat of vaporization. The transition from the liquid phase to a crystalline phase occurs at a fixed temperature, determined by the external pressure, and the transformation releases a quantity of heat per unit mass, L_f , the latent heat of fusion. The transformations from the liquid phase are described by the Clapeyron equation relating the external pressure, p , to the temperature of the transition, T , the latent heat of transition, L , and the volume

change in the transition, ΔV . The equation is: $\frac{dp}{dT} = \frac{L}{T\Delta V}$. In

vaporization, ΔV is greater than zero for all substances, and therefore the boiling point always increases if the external pressure is increased. In fusion, ΔV is usually positive, but exceptions occur. The most notable exception is water, and for this substance there is a range of temperatures in which an increase of the external pressure decreases the freezing temperature. Other substances having this property are bismuth, germanium and antimony.

In contrast to the discontinuous behaviour described for crystalline phases, noncrystalline solids generally do not possess definite transition points but soften gradually to a liquid phase with increasing temperature.

The properties of the region near the critical point are of great interest and are only poorly understood. The best experimental evidence suggests that along the coexistence curve the density

varies as $\sqrt{1 - \frac{T}{T_c}}$, whereas the classical theory predicts a dependence of the form $\sqrt[3]{1 - \frac{T}{T_c}}$.

There exists no simple relationship between the pressure, volume and temperature of a liquid that can describe the entire fluid range. For small temperature and pressure changes from some fixed T_0 , p_0 , V_0 , a simple power series expansion is useful,

$$V = V_0 \left[1 + \frac{1}{V_0} \left(\frac{\partial V}{\partial T} \right)_{p_0} (T - T_0) - \frac{1}{V_0} \left(\frac{\partial V}{\partial p} \right)_{T_0} (p - p_0) \right] \quad (1)$$

but this equation of state cannot ordinarily be used if $(p - p_0)$ is greater than 100 atm. and $(T - T_0)$ is greater than 10°C .

Liquids in contact with their own vapours or air possess a surface tension that, unless opposed by external forces, causes the interface to assume the configuration of minimum area. In the absence of gravity and other forces, the stable form of a mass of liquid is spherical. Surfaces between a liquid and a solid or another immiscible liquid are also characterized by interfacial tensions, which determine whether the liquid in question will spread on (wet) the other material.

The electrical properties of liquids are determined by the density of charge carriers. With the exception of liquid metals, molten salts and solutions of salts in ionizing solvents, the electrical conductivities of liquids are small. In molten salts and solutions of salts the current is carried by the ions of the salt, whereas in liquid metals the current is carried by electrons.

When the density of charge carriers is zero, a liquid may still react to an impressed electric field by the rotation of permanent molecular dipoles. The dielectric constants of nonpolar liquids (for which the molecular dipole moment vanishes) are generally in the range of 1.00 to 3.00. Because of the possibility of storage of the field energy by partial alignment of molecular dipoles, the dielectric constants of polar fluids are much larger, of the order of 10 to 100 times those of nonpolar liquids. For example, at 25°C , the dielectric constant of water is 78.54. In general, with the exception of liquid crystalline phases, the electrical properties of liquids are isotropic. In nonpolar liquids the refractive indexes in the visible spectrum do not differ greatly from the

square root of the low-frequency dielectric constant, and in polar liquids the refractive indexes in the visible spectrum are of the same magnitude as those of nonpolar liquids.

The absorption spectra of liquids cover the entire electromagnetic spectrum. Dispersion in the radio-frequency region arises from dipolar orientation and depends primarily upon the interaction between molecules. Dispersion in the higher frequency range arises primarily from absorption within one molecule. Although the absorptions in the latter case also occur in the isolated molecule, changes in frequency and intensity, as well as the broadening of the band structure of the vapour spectrum, are observed on account of the perturbing influence of intermolecular forces.

For the entire electromagnetic spectrum the liquid properties can be described by a frequency-dependent dielectric constant, $[\epsilon(\omega)]$, $\epsilon(\omega) = \epsilon'(\omega) + i\epsilon''(\omega)$ with storage of energy characterized by ϵ' , dissipation of energy by ϵ'' and with i equal to the imaginary quantity $\sqrt{-1}$. The storage and dissipation terms are related by a general dispersion formula, due to H. A. Kramers and R. Kronig,

$$\epsilon'(\omega) = 1 + \frac{1}{\pi} \rho \int_{-\infty}^{\infty} \frac{\epsilon''(x)}{x - \omega} dx \quad (2)$$

$$\epsilon''(\omega) = -\frac{1}{\pi} \rho \int_{-\infty}^{\infty} \frac{\epsilon'(x) - 1}{x - \omega} dx + \frac{4\pi\sigma}{\omega}$$

with ρ indicating principal part and σ the conductance of the liquid.

Molecular Properties of Liquids at Equilibrium.—The structure of substances on the molecular scale is determined by the balance between the ordering influence of intermolecular forces and the disordering influence of thermal motion. At low temperatures the influence of intermolecular forces predominates to give the completely ordered structural characteristics of the crystalline lattice. At high temperatures the influence of thermal motion predominates to give the random and featureless structure of a gas. The structure of liquids corresponds to a degree of order intermediate between that of the crystalline solid and that of a gas.

The structure of an ideal crystal is described by the theory of space lattices. There exists a fundamental unit of structure composed of a small number of atoms or molecules in a definite geometric configuration. The crystal lattice is built up as a periodic repetition of the fundamental unit in the three directions of space. Real crystals possess various types of disorder such as missing atoms, atoms in positions intermediate between lattice positions, lattice dislocations and mosaic structure as well as thermal disorder associated with lattice vibrations and lattice defects.

When a crystalline solid melts to the liquid state, the long-range order of the crystal is destroyed. However, a residue of local order persists in the liquid state with a range such that the vestigial order becomes imperceptible at distances greater than several molecular diameters. The local order characteristic of the liquid state is described in terms of a pair correlation function, $g_2(R)$ (radial distribution function), defined as the ratio of the average molecular density, $\rho(R)$, at a distance R from an arbitrary molecule to the bulk density, ρ_0 of the liquid: $\rho_2(R) = g_2(R)\rho_0$. When $g_2(R)$ is unity everywhere, the fluid is completely disordered, a structural feature characteristic of dilute gases. De-

FROM J. G. KIRKWOOD, V. A. LEWINSON AND B. J. ADLER, "JOURNAL OF CHEMICAL PHYSICS"

COMPARISON OF THEORETICAL AND EXPERIMENTAL RADIAL DISTRIBUTION FUNCTIONS, OR $g(x)$, FOR LIQUID ARGON AT 91.8°K AND 1.8 ATMOSPHERES

The points represent experimental data. Solid line represents theoretical function in which λ is a parameter related to the density of the liquid and ϵ is depth of potential energy well. Thus, λ corresponds to a ratio of actual volume to volume of close packing equal to 1.22 and to a temperature such that the depth of the potential well divided by kT is 1.2

partures of $g_2(R)$ from unity measure the local order established by a molecule in the arrangement of its neighbours. For the representative liquid $g_2(R)$ is a curve with a series of rapidly damped maxima and minima (see figure). The positions of the maxima roughly correspond to the first several co-ordination shells of the crystal lattice characteristic of the parent solid. The minima roughly correspond to distances intermediate between the co-ordination shells. The area under a peak of $g_2(R)$ is related to the excess molecular density (relative to the bulk density) and therefore is related to a rough co-ordination number. The radial distribution function specifies only the average local density, from which significant statistical fluctuations must occur as the neighbours of a specified molecule are interchanged with other molecules in the course of thermal motion. Other observable effects of the statistical fluctuations are the diffuse peaks of $g_2(R)$ (as compared with the precise order of a crystal) and the rapid approach of $g_2(R)$ to unity as R increases beyond a few molecular diameters.

The experimental determination of the radial distribution function is based upon the determination of the coherence of waves scattered from different points in the liquid. Since $g_2(R)$ differs from unity for small R only, coherence is only obtained with wave lengths smaller than the range of molecular correlation. Such wave lengths are provided by X-rays and thermal neutrons. A liquid will also scatter visible light. Since the wave length of visible light is very much greater than the range of molecular correlation, only an average over $g_2(R)$ is determined in this wave length region.

If the intensity of scattered radiation making an angle ϑ with the incident radiation is denoted $I(\vartheta)$, then

$$I(\mu) = |f|^2 \left[N + \frac{4\pi N(N-1)}{V} \int_0^\infty (g_2(R) - 1) \frac{\sin \mu R}{\mu R} dR \right] \quad (3)$$

$$\mu = \left(\frac{4\pi}{\lambda} \right) \sin \frac{\vartheta}{2}$$

where f is the scattering form factor of the atoms of which the liquid is composed, λ is the wave length of the radiation and N is the number of molecules in the volume, V , of liquid.

To obtain $g_2(R)$, the integral must be inverted, using the Fourier integral theorem. Lack of data at the extremes of the angular range often introduces errors in the functions deduced from the observed scattering intensities. Small molecular separations affect the scattering at large angles, and vice versa, so that accurate values of $g_2(R)$ for small R , which require $I(\vartheta)$ near $\vartheta = \pi$, are difficult to determine because $I(\vartheta)$ decreases very rapidly as ϑ approaches π .

If the molecules of the liquid interact with a pairwise decomposable potential energy of interaction, $U(R)$, it can be shown that

$$pV = RT - \frac{2\pi N}{3} \rho_0 \int_0^\infty R^3 \frac{dU}{dR} g_2(R) dR \quad (4)$$

$$L = RT = 2\pi N \rho_0 \int_0^\infty R^3 U(R) g_2(R) dR \quad (5)$$

where R is the gas constant with a value of 1.987 kg.cal./mole degree. In molecular units, $R = N_0 k$ where k is the Boltzmann constant (1.38×10^{-16} erg/molecule-deg.) and N_0 is the Avogadro number (6.02×10^{23} molecules/mole). A molecular theory of liquids requires an interpretation and calculation of $g_2(R)$.

Quasi-crystalline models of local liquid structure may be used to advantage in the interpretation of the radial distribution function. While it is recognized that long-range crystalline order is absent, the local arrangement of the neighbours of each molecule is regarded as a blurred replica of the first several co-ordination shells of a single crystal lattice or of a superposition of several lattice types. The number of neighbours in each diffuse co-ordination shell is estimated as $\int 4\pi R^2 \rho_0 g_2(R) dR$ under the corresponding peak of the radial distribution function. In this way it is inferred

that, for example, the local structure of liquid mercury corresponds to an approximately close-packed array of spheres. For the case of water, the liquid is regarded as a three-dimensional net in which each water molecule is linked to four neighbours by hydrogen bonds. By superposing co-ordination structures of β -quartz, tridymite and close-packed types, a synthetic $g_2(R)$ may be constructed that is in substantial agreement with experiment. At low temperatures the β -quartz structure predominates, and at high temperatures the contribution of the close-packed structure increases.

In a similar manner the structure of liquid hydrocarbons is represented as approximating the arrangement realized in the axial close packing of slender rods. The X-ray scattering curves of aliphatic alcohols exhibit inner peaks not observed for the corresponding hydrocarbons. This peak may be qualitatively interpreted if it is assumed that the alcohol molecules are linked in chains by hydrogen bonds between the hydroxyl groups while the aliphatic groups remain approximately close packed as in the corresponding hydrocarbons.

The quasi-crystalline interpretation of the liquid pair correlation function can also be used to advantage in discussing the dielectric constant. When neighbouring molecules are strongly correlated, as for example by the presence of a hydrogen bond, it can be shown that

$$\epsilon'(0) - n^2 = \frac{3\epsilon'(0)}{2\epsilon'(0) + n^2} \cdot \frac{4\pi N}{3kTV} \mu^2 (1 + \bar{\epsilon} \langle \cos \gamma \rangle) \quad (6)$$

with n the refractive index and where $\langle \cos \gamma \rangle$ is the average of the cosine of the angle between neighbouring dipoles with electric moment μ and there are $\bar{\epsilon}$ nearest neighbours to any dipole. J. G. Kirkwood has calculated $\epsilon'(0) = 63$ for water at 300° K. whereas the observed value is 78. The predicted temperature dependence of $\epsilon'(0)$ is also in fair agreement with observation. Similar agreement between theory and experiment is obtained when other hydrogen-bonded liquids, such as the alcohols, are considered.

In general, quasi-crystalline models of a liquid are of most use when the correlation between molecules is very strong because of the presence of a specific orientation-dependent force, such as a hydrogen bond. For simple monatomic fluids, quasi-crystalline models are far less useful and often lead to erroneous predictions because of their inherent overestimate of the molecular ordering. For monatomic fluids, $g_2(R)$ computed from a quasi-crystalline model has oscillations above and below the asymptotic value of unity as much as ten molecular diameters from an arbitrary molecule, whereas the observed $g_2(R)$ has reached unity after only three or four molecular diameters.

A different kind of quasi-crystalline model can be used to attempt to understand the properties of liquids. In this model it is supposed that the molecules are located at the points of a hypothetical lattice spanning the liquid volume. Then one molecule is allowed to move away from its lattice point, all other molecules remaining fixed in position. The motion of the wandering molecule is determined by the force field of the neighbouring molecules, which form a cage that prevents the wanderer from straying very far from the initial lattice point. Each molecule is then assumed to behave in the same manner so that the free volume available for the motion of any one molecule is related to the equation of state by

$$p = RT \left(\frac{\partial \ln V_f}{\partial V} \right)_T - \left(\frac{\partial L}{\partial V} \right)_T \quad (7)$$

with V_f the total free volume of the liquid. This model predicts the energy of the liquid fairly accurately, but the predicted entropy is too small, a reflection of the overestimate of the correlation between molecules.

A much more promising approach to the theory of liquids is through direct calculation of $g_2(R)$ without any appeal to special models. The principal difficulty centres around deriving a closed equation for $g_2(R)$. Because a pair of molecules interacting with third body molecules requires the specification of the molecular

density of triplets of molecules, all rigorous equations for $g_2(R)$ depend upon a knowledge of the three-molecule correlation function. The approximations made in the theory take one of two forms—either the three-body correlation is expressed in terms of two-body correlations (Kirkwood) or an attempt is made to compute certain classes of contributions (by no means all contributions) to $g_2(R)$; the contributions correspond to simple ways in which a third molecule interacts directly or indirectly with a chosen pair of molecules. These contributions can usually be written as a formal series, in principle exact if all terms are evaluated.

Calculations have now been carried out in the case of theories based on both of these two alternatives. A comparison of the theoretical and experimental radial distribution functions is given in the figure for liquid argon at 91.8° K. and 1.8 atm. pressure. In general the theoretical equations of state available predict too large a compressibility. It is likely that the principal source of error is in the approximate relationship assumed to exist between the density of molecular pairs and molecular triplets.

Macroscopic Description of Dissipative Processes.—Dissipative processes arise from the transport of mass, momentum and energy. In each case there exists a phenomenological relationship between a flux and the force that is responsible for the flux. In the cases of energy and mass transport, the Fourier and Fick equations apply,

$$\begin{aligned} \mathbf{q} &= \kappa \nabla T \\ \frac{\partial T}{\partial t} &= \kappa \nabla^2 T \\ \mathbf{J}_m &= D \nabla c \\ \frac{\partial c}{\partial t} &= D \nabla^2 c \end{aligned} \quad (8)$$

with \mathbf{q} and \mathbf{J}_m the energy and mass fluxes, κ and D the coefficients of thermal conductivity and diffusion, and c the concentration of one of the two components in the medium wherein diffusion is occurring. In the case of momentum transport the stress tensor σ and the rate of strain $\dot{\epsilon}$ play primary roles. For a Newtonian fluid the principal shearing stresses are proportional to the corresponding rates of strain and

$$\sigma = [-p + \left(\Phi - \frac{2\eta}{3}\right) \nabla \cdot \mathbf{u}] \mathbf{I} + 2\eta \dot{\epsilon} \quad (9)$$

with Φ and η the coefficients of dilatational and shear viscosity, \mathbf{u} the fluid velocity and \mathbf{I} the unit tensor. The stress law (9) when introduced into the equation of motion of the fluid leads to the Navier-Stokes equation—the starting point for the study of fluid dynamics.

The coefficients κ , D , η and Φ may be determined experimentally by a variety of methods based upon suitable solution of the appropriate differential equation. It is found that all of the transport coefficients vary when the temperature and density of the liquid are varied. It is observed that at constant external pressure D increases exponentially and η decreases exponentially as T is increased. Under the same conditions κ is much less sensitive to changes in temperature than are η and D . The dilatational viscosity, Φ , is partially responsible for the attenuation of sound in a liquid. It has not been measured for simple systems such as liquid argon, krypton, etc. For complex liquids, such as polyhydric alcohols, Φ can be related to the relaxation of the internal motions of molecules in the liquid. For most simple liquids D is of the order of 10^{-5} cm.²/sec., κ of the order of 10^{-4} cal./cm. sec. °C., and η of the order of 5×10^{-3} dyne sec./cm.². For liquids with extensive hydrogen bonding, such as polyhydric alcohols, η may be very much larger, as it also is for long-chain molecules in general.

The preceding comments refer to the static or steady-state properties of a liquid. Dissipation also accompanies relaxation processes at high frequency. Thus, the imaginary part of the dielectric constant, $\epsilon''(\omega)$, describes energy loss due to conduction (for which $\epsilon''(\omega) \approx \frac{4\pi\sigma}{\omega}$, corresponding to ohmic losses, with σ the specific electrical conductivity) as well as losses due to the in-

ability of dipolar molecules to follow the impressed electric field if the frequency becomes much larger than the inverse of the relaxation time for reorientation of the dipole. The relaxation time for reorientation is (approximately) proportional to the viscosity of the liquid.

Molecular Interpretation of Dissipative Processes.—In a dilute gas the transport of mass, momentum and energy occurs by the movement of individual molecules from one region of space where the local variables are c_1, \mathbf{u}_1, T_1 to another region of space where the local variables are c_2, \mathbf{u}_2, T_2 . The transfer requires the actual displacement of molecules. In a crystalline solid the transfer of energy is effected by the lattice vibrations without requiring, on the average, the displacement of any molecules. Also, in the gas a molecule may move freely until it collides with another molecule, but in the solid molecular displacement from one to another lattice site requires imperfections—i.e., vacant lattice sites or dislocations—before motion is possible. In a liquid the motion of a molecule is very complex and has characteristics intermediate between those of the gas and the crystalline solid.

The quasi-crystalline model of a liquid has been extensively used to interpret the relationship between liquid structure and the transfer of mass, momentum and energy. In each case it is assumed that the basic step requires thermal activation, i.e., that an intermediate geometric configuration midway between the initial and final molecular structures exists, and that the ratio of the concentration of such activated states to the concentration of initial states is determined by $\exp(-\frac{\Delta G^*}{RT})$ with ΔG^* the free energy of activation. This theory predicts that D and η vary exponentially with temperature, as is observed. The quasi-crystalline theories do not relate the parameters required to calculate D , κ and η to the intermolecular potential or to $g_2(R)$ and therefore are really parametric representations rather than molecular theories. Moreover, they cannot account for the temperature dependence of D and η if the density rather than the pressure is maintained constant.

A better picture of motion in a liquid is provided by a model proposed by M. H. Cohen and D. Turnbull. In this model a molecule can only move if a void of critical size, V^* , opens up adjacent to the molecule. It is supposed that such voids can occur by the occasional random coalescence of the free volume of the liquid. If a is the diameter of a molecule, Cohen and Turnbull show that

$$D = \frac{a^2}{6} \left(\frac{3kT}{m} \right)^{\frac{1}{2}} e^{-\gamma V^*/V_f} \quad (10)$$

where γ is a numerical constant and m is the mass of the molecule. This equation accurately accounts for the behaviour of complex molecules and provides an interpretation of the fluid behaviour in the glass region where the simple form of the activated state model fails. Equation 10 does not, however, accurately describe the behaviour of simple fluids. For the case of simple molecules the intermolecular repulsive potential rises much less steeply than does the intermolecular repulsive potential of complex molecules, and this difference is one source of the errors inherent in equation 10.

In a liquid any given molecule is in continuous interaction with all its near neighbours. To visualize a typical dynamical event, a pair of molecules may be imagined to have a near-encounter during which strong repulsive forces act. After this repulsion separates the pair, the individual molecules move erratically in the rapidly fluctuating force field generated by the neighbouring molecules. The motion of a molecule in a liquid is therefore analogous, in some ways, to the motion of a massive Brownian particle. In this description of the liquid, the dynamical properties of a molecule are described by a friction constant, $\zeta = kT/D$. The formulation referred to is improved if it is recognized that the motion of a molecule forces a modification of the local structure of the liquid away from the equilibrium structure, but the calculation of nonequilibrium pair correlation functions is extremely difficult. The nonequilibrium pair correlation function also appears in the analysis of the inelastic scattering of neutrons from liquids.

Exact formal relationships for the various transport coefficients of a liquid can be written in terms of an equilibrium average of the autocorrelation functions for certain dynamical variables. A typical result, due to Einstein, is

$$D = \frac{1}{3m^2} \int_0^\infty \langle \mathbf{p}(t) \cdot \mathbf{p}(t+s) \rangle ds \quad (11)$$

where the angular brackets refer to an average over the equilibrium ensemble representing the liquid and \mathbf{p} is the momentum of a molecule. Relationships similar in structure to equation 11 have been derived by R. Kubo and H. Mori for the coefficients η , κ and the electrical conductivity, σ .

LIQUORICE: see LICORICE.

LIQUOR LAW. The nature and effect of intoxicants are so serious, especially in the case of persons who use them in excess, that a broad range of public regulation has been imposed upon both their manufacture and distribution. User and dealer are thus separately affected, the one by "private" law and the other by "public" law, as has been the case since ancient times. Hammurabi's code, in its provisions respecting drinking places, sought to protect public order first and to regulate price next. In biblical days drunkenness was denounced generally as well as in particular classes such as rulers, priests, women and labourers.

Subsequent legal history endlessly restates, in one form or another, such age-old themes. Courts of justice have fashioned rules of decision for cases in which it appears that use of alcoholic beverages has impaired the legal capacity or responsibility of a party to an act or transaction. The rise of legislation and regulation in the 19th century included the development of a variety of forms for public control of the liquor traffic. In 1890 the supreme court of the United States, in turning aside attacks upon such governmental activity, pronounced there to be "few sources of crime and misery to society equal to the dram shop, where intoxicating liquors . . . are sold indiscriminately to all parties applying" (*Crowley v. Christensen*, 137 U.S. 86).

UNITED STATES

Liquor law and regulation in the United States reflects both the peculiarities of the federal system and the practice of the states to place partial control in their local subdivisions. The first of these limits the activities of the national government; the second divides the remaining area of regulation between state and local governments.

Apart from the prohibition era of 1920 to 1933 (see PROHIBITION) the main interests of the federal government in liquor production and commerce have been (1) the collection of revenue; and (2) the protection of regulations introduced by the states. But, of these two, taxation of the liquor industry has been its historic preoccupation. Indeed, the first tax on distilled spirits, recommended by Alexander Hamilton and enacted in 1791, provoked armed resistance which tried the resources of the new republic and required it to use troops to keep order and enforce the law (see WHISKY INSURRECTION). These revenue-regulation laws have grown until they now comprise about 1,000 sections of the United States code. They place the entire industry under administrative oversight except insofar as brewers, retailers and state-operated stores are left to state law and administration. Gallonage and occupational taxes are imposed, distilled spirits plants and wineries are supervised, and importations are subject to duties or otherwise controlled. Various trade practices are regulated. Further, aside from liquor laws relating to Indians, there are only bits of legislation respecting the use of intoxicating liquors by federal employees and seamen or harbour workers.

In one respect, however, the customary protection of the federal revenue has local effect. As federal, state and local taxes on intoxicating liquors mount under pressures for increases in public

funds, illegal manufacture and sale of such beverages without payment of such taxes becomes more profitable; and this incentive swells the ranks of the country's bootleggers. Such activities are violations of many federal laws. Year after year the annual reports of the secretary of the treasury and of the commissioner of internal revenue recite the numbers of arrests made in enforcing these laws. In addition, there are seizures of stills (approximately 10,000 per year), of illicit liquor supplies (hundreds of thousands of gallons), of raw materials for such manufacture (millions of gallons), of vehicles used in such operations (thousands), and of other property so involved (millions of dollars annually). Rewards and paid informers play an important part in these efforts. There is a special program to keep the necessary raw materials, particularly sugar, from bootleggers. It is worthy of note that a rise in the market price of sugar is in itself an effective deterrent to illicit operations. (See BOOTLEGGING.)

Otherwise the protective function of federal law rests upon the few pieces of national legislation which, in simple terms, enable states to regulate the whole of the liquor traffic within their borders. The Wilson act of 1890 declares that intoxicating liquors transported into any state are to be subject to the operation and effect of its laws as though originally produced there. The Webb-Kenyon act of 1913 prohibited outright such transportation in violation of any law of such state. Lastly, in the 21st amendment to the federal constitution, by which national prohibition was repealed, a provision was included to the same effect as the Webb-Kenyon act. The result was to elevate the latter's proscription to the status of a constitutional provision of independent operation repealable only by amending the constitution.

State Liquor Law.—Under the federal system the regulation of sales of liquor to consumers and the definition of legal relations affected by intoxication fall primarily within the police powers of the states. All of the states define offenses in which drunkenness or the supplying of liquor to unauthorized persons are material elements. Examples include drunken driving, breach of peace and contributing to the delinquency of a minor. Under certain circumstances, however, intoxication may mitigate criminal liability. Thus, in the United States as in England, most courts recognize that drunkenness may relieve an accused of liability for a crime, provided the defendant was rendered incapable of forming the purpose or possessing the knowledge required to be shown in proving the offense (see CRIMINAL LAW). On the other hand, impairment of mental faculties by reason of intoxication generally affords no defense for the civil wrongs such person may commit. Under the stringent dramshop legislation widely adopted in the United States, civil liability for wrongs committed by the intoxicated person or injuries sustained by him may fall on those who sold or supplied such person with liquor. A multitude of other civil consequences are associated with intoxication. Thus the contracts, deeds or will of the intoxicated person may be rendered invalid. Habitual drunkenness may provide his spouse with grounds for divorce, result in the loss of custody of his children or loss of his licence to practise a profession. By the beginning of the 1960s the social problems of alcoholism as manifested in the skid-row areas of large cities produced efforts in some localities to supplement repressive measures by public programs of assistance and therapy.

Much more explicit in form are the state regulations respecting commerce in intoxicating liquors. These systems, based upon legislation rather than the less readily perceptible case-to-case adjudication by courts in private lawsuits, range from outright prohibition or local option (*q.v.*) to various forms of state or local licensing. In between are forms of direct state participation as the sovereign wholesaler or retailer with or without supplementation by private purveyors. Adoption of such a "state store" system without any other form of retailing echoes the theme, popular at the time of the repeal of national prohibition in 1933, that it was the saloon rather than liquor that should be prohibited.

Whatever its plan of regulation, each state has a variety of criminal and civil penalties to enforce its particular system. Each state provides for either state-wide or local administration, by special or ex officio personnel, as well as for taxes, prices, sale

times and limitations upon advertising. Sales to minors are prohibited. About a third of the states maintain state stores for sales to consumers by the package (bottle or more, not for consumption on the premises), or by the drink as well as by package, of some or all types of intoxicating liquors (spirits, wine, beer). A few of these permit no other form of retailing, but most allow sales by the drink by retail licensees such as hotels, clubs and restaurants of some or all such liquors. The other states rely upon licensing alone for both wholesalers and retailers of beverage alcohol. They permit retail sales by the package, or by package or drink, usually the latter combination. (C. McF.)

UNITED KINGDOM

The English System.—The common law of England imposes no control on the keeping of inns, taverns and alehouses apart from the requirement that they shall not constitute a nuisance. Statutory control, however, commenced with the act of 1552, which introduced the system of licensing and brought common ale, or tipping, houses under the vigilance of justices of the peace. The licensing system aimed to suppress drunkenness by limiting the number of public houses and by other controls. A magistrate's certificate was required for the allocation of an excise licence, the sole authority for the sale of liquor.

Control by the lay justices is accordingly the basis of the law and is practically complete except for certain historical exemptions. The Carlisle area in Cumberland is subject to a system of state ownership: no person unless acting on behalf of the secretary of state for home affairs may sell intoxicating liquor by retail or supply it in any licensed premises or registered club. Ancillary functions of the home secretary in this area include the provision and maintenance of hotels and inns where alcoholic liquor is sold.

The main provisions relating to the law of licensing administration were eventually consolidated, and are for the most part to be found in the Licensing act, 1953, as amended and amplified by the Licensing act, 1961, and the Customs and Excise act, 1952. The 1952 act classifies the excise liquor licences that may be authorized under the following heads: (1) manufacturers'; (2) wholesale dealers'; (3) retailers'; (4) occasional; (5) passenger aircraft; (6) passenger vessel; and (7) railway passenger vehicle.

Methods and Conditions of Licensing.—For the purpose of granting a retailers' licence England and Wales are divided into licensing areas comprised of committees of five or five members of the petty sessional division of a county and a borough having a separate commission of the peace. The divisional licensing justices (there must be a quorum of at least three) receive applications for the granting of a new licence, or the renewal or transfer of an old, at their general annual meeting in the first fortnight in February each year, and they are empowered to deal with these applications as they think fit and proper. The meeting of the justices must take place in public. The proceedings are of a quasi-administrative order, the meeting of the justices not constituting a court of summary jurisdiction for licensing purposes. All qualified justices are entitled to sit. The discretion of the justices, although absolute, is required to be exercised judicially. Any person liable to real bias may not sit as a licensing justice and if he does the order may be quashed on that ground. The justices must take into consideration both the character of the application and of the premises. The applicant must not be any sheriff's officer, or a person convicted of felony or certain other offenses, and must be of good repute. The premises must be structurally adapted to the class of licence required and the magistrates may in granting the licence impose conditions as to the alteration of the structure of the premises. No alteration in any on-licensed premises may be made without the consent of the justices. At the hearing any member of the public may be heard in objection to the application provided that such objection is advanced on public grounds. All evidence must be tendered on oath.

The decision of the justices whether to grant the application is by majority vote. Once granted the licence continues in force for a year. The grant of a new licence requires confirmation by the county or borough Confirming and Compensation committee at quarter sessions. In the event of failure to renew an old licence,

compensation is payable (after reference has been made to the compensation authority) as calculated on the difference between the value of the premises licensed and unlicensed; such a sum is met out of an "insurance" fund subscribed to by all licence holders.

There is a right of appeal from licensing justices to quarter sessions against the grant or refusal of a licence and from a number of other decisions; under s. 84 of the Magistrates' Court act, 1952, there is a right of appeal from magistrates' courts (as distinct from licensing justices) to quarter sessions in respect of a refusal to issue or renew a club registration certificate and of certain other orders relating to clubs (see *Clubs* below). No appeal is permissible to the superior courts of the country, but the divisional court of the queen's bench division exercises a supervisory jurisdiction over inferior tribunals and can remedy any defects in justice of a fundamental nature which may have been done.

The grant of a justices' licence entitles the holder to an excise licence, the authority for the sale of liquor, but upon forfeiture of the justices' licence the excise licence becomes void. Any person who sells by retail any intoxicating liquor without a justices' licence is liable to a fine of £50 or to imprisonment for one month. The holder of a justices' licence must have his name with the word "licensed" painted on the premises in a conspicuous position.

Under the common law of England the holder of a licence is not under a legal duty to open during the permitted hours, nor to serve all comers unless he be a common innkeeper, in which case he has no right to pick and choose among sober and orderly customers whom he will serve. In general throughout the United Kingdom there is strict supervision of the beverage liquor traffic, and in addition to the penalties under the Licensing act defaulting licensees may be disqualified. Hence it is incumbent on the holder of a licence not to permit drunkenness or any violent, quarrelsome or riotous conduct on the premises; he must not permit them to be the habitual resort of reputed prostitutes, or knowingly harbour thieves or reputed thieves; nor must he allow his house to be used for gaming or betting.

The 1961 act makes a considerable departure from previous legislation by providing that, except on certain specified grounds, licensing justices shall not refuse an application duly made for the grant of a new justices' on-licence or for the renewal of a justices' on-licence in respect of a restaurant licence or for a new type of residential licence, under which proprietors of guesthouses are authorized to supply alcoholic drinks to residents or to private friends being entertained by residents. The 1961 act also goes some way to increase the control of magistrates and the police over the sale and supply of intoxicating liquor in club premises.

Permitted Hours.—The 1961 act fixes the permitted hours during which on-licensed premises may remain open to the public. It is an offense, punishable by £30 fine, for any person to serve to another any intoxicating liquor to be consumed on or off the premises, outside the permitted hours, unless he is resident on the premises or is consuming a drink with a meal ordered within half an hour after the conclusion of the permitted hours, or unless he is a bona-fide friend of the landlord being entertained on the premises at the landlord's own expense. The permitted hours vary slightly as between the metropolis (so defined) and other parts of the country, and as between weekdays and Sundays, Christmas day and Good Friday. The Licensing (Scotland) act, 1962, follows broadly the same lines as the 1961 act for England and Wales.

Protective Provisions.—Under the 1953 act no child under the age of 14 is allowed into any bar. Liquor is not allowed to be sold for consumption on the premises to any person under the age of 18; but if, however, the individual is 16 or over he may take beer, porter, cider or perry with his meal provided that it is consumed in an open part of the premises and not at the bar. A bona-fide error as to the age of the child is a good defense to a charge under this head. By the Children and Young Persons act, 1933, it is an offense for anybody to give intoxicating liquor to any child under the age of five save in a case of medical necessity.

The Licensing act, 1953, makes it an offense to sell liquor otherwise than in a standard imperial measure. Credit sales are forbidden and a customer must pay cash for the drink when it is sold.

Clubs.—Clubs which sell intoxicating liquor come under the

control of the Licensing act, 1953, as amended by the Licensing act, 1961, which requires registration as a condition to the supply or sale of drink. The secretary of a registered club is bound in January of each year to furnish to the clerk of the justices a return containing certain statutory particulars. At the same time he must deliver to the commissioners of customs and excise a statement of purchases of intoxicating liquor during the preceding year. Penalties are imposed for the supplying or keeping of liquor in an unregistered club. Magistrates are empowered if reasonable cause be shown to issue search warrants for the entry into clubs by constables to ensure that the law is not being evaded.

Scotland and Northern Ireland.—A practically parallel method to the system of licensing in force in England and Wales is to be found in Scotland and Northern Ireland. The duties and powers of the Scottish licensing courts are laid down in the Licensing (Scotland) acts, 1903 to 1949. In Ulster control is effected in the main by the Intoxicating Liquor Licensing acts (Northern Ireland), 1923 and 1927.

Rules on Drunkenness.—The Licensing acts control liquor at its source; but other statutory provisions also discourage drunkenness. Underlying the criminal law of the country is the principle expounded by the house of lords in the leading case of *Beard v. Director of Public Prosecutions* (1920) A.C. 249, as follows: (1) that insanity whether produced by drunkenness or otherwise is a defense to the crime charged; (2) that evidence of drunkenness which rendered the accused incapable of forming the specific intent essential to constitute the crime should be taken into consideration with the other facts proved in order to determine whether or not he had this intent; and (3) that evidence of drunkenness falling short of a proved incapacity in the accused to form the intent necessary to constitute the crime, and merely establishing that his mind was affected by drink so that he more readily gave way to some violent passion, did not rebut the presumption that a man intended the natural consequences of his acts. In *R. v. McCarthy* (1954) 2 A.E.R. 262, it was held by the court of criminal appeal that unless a man is in such a complete and absolute state of intoxication as to make him incapable of forming the intent charged, drunkenness which may lead him to attack another in a manner which no reasonable, sober man would do cannot be pleaded as provocation reducing the crime from murder to manslaughter if death results. In *Broadhurst v. the Queen* (P.C. 1964 2 W.L.R. 38) the Judicial Committee of the Privy Council threw more doubt on the applicability of some of the principles adumbrated in *Beard's* case and Lord Devlin suggested (at L. 52) that the test is simply whether the accused had the capacity at the material time to form the intent.

Drunkenness by the common law of England is not an offense in itself, but by statute drunkenness accompanied by some other action may be. Thus if a person is found drunk in any highway or other public place, whether a building or not, and is incapable of taking care of himself he is liable to be apprehended and on conviction to pay a fine of 10s.

Riotous or disorderly behaviour in a public place while drunk is an offense; to be drunk while in charge in a public place of a horse, cattle or a steam engine or in possession of a loaded firearm is likewise an offense. A person may not procure intoxicating liquor for consumption by a drunken person nor aid and abet such a person to obtain it. By s. 287 of the Merchant Shipping act, 1894, it is an offense to be drunk and persist, after being refused admission on that account, in attempting to enter a passenger steamer; it is also an offense, being drunk on board a passenger steamer, to refuse to leave when requested; and the Civil Aviation act, 1949, makes similar provisions for air travel.

Section 6 of the Road Traffic act, 1960, as amended by s. 1 of the Road Traffic act, 1962, and the fifth schedule thereto defines the offenses of and imposes penalties for, respectively, driving or attempting to drive a motor vehicle on a road or other public place when unfit to drive through drink or drugs, and being in charge of a motor vehicle which is on a road or other public place (but not driving the vehicle) when unfit to drive through drink or drugs. Each offense carries substantial penalties, including disqualification from driving, which is obligatory for a period, in

the absence of special reasons to the contrary, for the first of these offenses and, in certain circumstances, for the second.

The Inebriates acts, 1879–98, provide for the licensing by local authorities of retreats and reformatories for habitual drunkards. A habitual drunkard is a person who, not being amenable to any jurisdiction in lunacy, is notwithstanding by reason of habitual intemperate drinking of intoxicating liquor at times dangerous to himself or others, or incapable of managing himself or his own affairs. Whether drunkenness is occasional or habitual is a question of fact for the court. A separation order can be made by a court of summary jurisdiction in favour of a wife on the ground that her husband is a habitual drunkard or a drug addict. Any habitual drunkard who is found to be such may upon conviction on indictment of an offense, and if the court be satisfied that the offense was committed under the influence of drink, be ordered by the court to be detained in a reformatory for a period not exceeding three years. (P. B. C.; W. T. Ws.)

COMMONWEALTH OF NATIONS

In Canada liquor legislation was based fundamentally on the licence system of the United Kingdom, but in its development it also followed closely the United States system. Thus, while the provinces had laws of varying stringency, they usually provided for licences modified by local veto. In 1901 the privy council decided the constitutional controversy over the respective powers of the dominion and the provinces; importation and manufacture were to be controlled by the dominion, distribution and sale by the provinces. Exceptions are the Northwest Territories and the Yukon, where retail is controlled by the dominion. Also, the Canada Temperance act is a dominion statute which applies to the whole of Canada.

The Canada Temperance act, 1878 (the Scott act), provided for local option in any city or county on petition of one-fourth of the electors at three-year intervals. Under this act a rapid growth of dry areas in the maritime provinces took place, while in other areas, where the Scott act was unpopular dry territory spread under provincial statutes. National prohibition, which received a majority of 13,687 in a total vote of more than 500,000 in an 1898 plebiscite, never gained enough support to secure enactment by the dominion government. After 1901 there was much legislation analogous to the U.S. Wilson and Webb-Kenyon acts (*see PROHIBITION*) to protect dry territory from invasion from surrounding wet areas. Unlike the United States, Canada, in abandoning total prohibition, abandoned also the licence system in favour of state monopoly. The Canada Temperance act, 1952, provided that upon the petition of one-fourth of the electors in any city or county an election must be held and if a majority is in favour part ii of the act takes effect by order in council. This prohibits the sale or keeping for sale of intoxicating liquor in the city or county, and the taking of liquor into it. Liquor purchased outside the city or county for personal use may be delivered to a person at his residence. A petition to revoke part ii results in a vote, and if a majority in favour is obtained a further order in council declares it revoked. Manufacturers' licences are granted to distillers and brewers under the Excise act, 1952. Under the Importation of Intoxicating Liquors act, 1952, the importation of liquor into any province from outside Canada or from another province is prohibited unless consigned to her majesty, the executive government or a government agency vested with the right of dealing in intoxicating liquor. (C. E. Ww.)

In Australia, each of the six states has its own machinery for liquor legislation. The states have a licence court, board or commission to supervise the enactment of laws, to consider applications for new licences and to reduce them. Funds for compensation for licences refused renewal are derived from special taxes, usually assessed on the volume of the liquor trade. Provision is also made for "local option" polls, at varying intervals, when total prohibition may be voted. In Queensland, since the 1958 amendment, 10% of the voters may petition for a poll and overrule the court's decision to grant a licence; in some states the number of licences is fixed, e.g., Queensland, but this is not the case in South Australia or Victoria. Hours of sales vary, as does

the minimum age of being served. Sales are prohibited on Sundays, but bona-fide travelers, *i.e.*, who have traveled a certain distance on the same day, may be served at certain hours.

In New Zealand, the Licensing Control commission (1948) supervises the issue of licences and other legal requirements; licensing committees (representatives of ratepayers) operate in the districts, but their decisions are subject to assent by the electors. District licensing trusts have also operated since 1944, residents of the district electing the trust; in 1949, two previously dry districts voted to have such trusts. Licensing hours are from 9 A.M. to 6 P.M.; no sales are permitted on Sundays, clubs and restaurants having special arrangements.

The 1950s saw in India a great drive to limit, and eventually prohibit, sales of liquor, the campaign being linked with the country's plans for economic development. Under the constitution, each state is empowered to introduce its own laws to effect this. The three states of Madras, Gujarat and Maharashtra had total prohibition by 1960; in others, advertising was being discontinued, sales were being prohibited, or merely discouraged, on certain days and liquor shops were being reduced in number.

(S. McC. L.; X.)

CONTINENTAL EUROPE

Before World War I continental European countries gave little legislative attention to the liquor traffic. It was generally licensed for revenue purposes, but control of beverage alcohol as a means of combating the evils of alcoholism was left to the local authorities and to ordinary police regulation. A strong and growing temperance and total abstinence movement in most countries, wholly individualistic in character, dated from the latter part of the 19th century in the countries of northern Europe, and in some of these countries steps toward liquor control were taken. World War I stimulated liquor control because of the need for food and manpower conservation. In Sweden, liquor rationing, introduced at the end of World War I, was abolished only in 1955. Very stringent laws apply to drivers under influence of alcohol, and a driver is penalized if his blood contains over 0.5% alcohol. Similar legislation applies in Norway. In Denmark, the punishment is 12 months' imprisonment or a fine; in Finland, three years' imprisonment is served and the driving licence withdrawn. In most European countries, including those of eastern Europe, propaganda campaigns have been launched in order to check drinking; and in Poland, since 1956, centres have been established to which people found drunk in the streets are taken, are kept till they become sober and are then required to pay for their accommodation.

Under the basic Licensing act of 1880 France imposed some restrictions on places with on-licences but left their regulation largely to local authorities. Taxation of the trade, then light, was greatly increased. Manufacture and sale of absinthe was prohibited by the act of March 1915, but the act was weakly enforced and there were many equally deleterious substitutes. After World War II both the production and consumption of alcoholic drinks in France went down, but according to some estimates 8,000,000 persons were still engaged either directly or indirectly in the liquor trade in France in 1955. In Nov. 1954 measures were announced for the tightening up of the liquor laws; in an endeavour to combat the national problem of alcoholism, taxes on drinks were to be increased by 20% and stricter penalties were to be imposed for offenses of drunkenness and against the licensing laws. Café proprietors breaking these laws rendered themselves liable to a fine of 1,000,000 fr. or to a term of imprisonment for one year. In 1961, a further law prohibited cafés and other liquor-selling establishments to be situated within certain distances of hospitals and other medical centres.

LIRI, a river of central Italy made up of two streams, the Rapido or Gari and the Liri. It is 158 km. (98 mi.) long and has a basin of 4,950 sq.km. (1,911 sq.mi.). The Liri has its sources near Cappadocia in the Simbruini mountains east of Rome, and traverses a long, narrow, scenic valley in its upper course as far as Arce. At the town of Isola del Liri there are two waterfalls. Below Arce the Liri enters its wide lower valley, where it receives the waters of the Sacco, draining the eastern part of the Ciocaria valley, and of the Melfa from the Abruzzi. Near San Giorgio it is joined by the Rapido and there becomes the Garigliano. It then turns southwest and empties into the Tyrrhenian sea near Minturno, forming the boundary between Lazio and Campania in its lower course. During the winter of 1943-44, as part of the Allied drive toward Rome, heavy fighting took place along the Rapido and the Liri, the Allied forces finally crossing in April 1944.

(G. Kh.)

LISA, MANUEL (1772-1820), pioneer American fur trader on the Missouri river, was born in New Orleans, La., on Sept. 8, 1772, the son of Christopher de Lisa, a native of Spain. He entered the fur trade at St. Louis, Mo., at an early age and soon became one of the leading traders on the upper Mississippi. The Spanish government granted him a monopoly of the trade with the Osage Indians in 1802, but it ended with the transfer of the upper portion of the Louisiana territory to the U.S. in 1804.

Lisa became associated with a number of successful fur companies, including the St. Louis Missouri Fur company, of which William Clark of the famous Lewis and Clark expedition was resident agent. Lisa himself led a number of expeditions and in 1807 established a trading post at the mouth of the Bighorn river in what is now the state of Montana. In 1808 he built Ft. Raymond there for trade with the Crow Indians. It was later known as Ft. Manuel and was the first such outpost on the upper Missouri river.

Ft. Manuel was abandoned in 1811. In a famous race that year the river barge of a party led by Lisa overtook, at the Niobrara river, a group of boats sent out by the John Jacob Astor interests. Near what later became the site of Omaha, Neb., Lisa established Ft. Lisa, which from 1813 to 1822 was the most important post on the Missouri, controlling trade with the Omaha, Pawnee, Otoe and other neighbouring Indians. In 1814 William Clark, who had left the fur company and become governor of the Missouri territory, appointed Lisa subagent for the Indian tribes on the Missouri above the mouth of the Kansas river. Lisa died at St. Louis on Aug. 12, 1820.

LISBON (Port. LISBOA), the capital and chief port of Portugal and capital of a district of the same name, stands at the westernmost point of the mainland of Europe, on the right bank of the Tagus (Port. Tejo) near its mouth. Built on the slopes of a range of small hills above the river's mouth and estuary (the former a channel 2 mi. wide and 8 mi. long, and the latter a bay 2 mi. long and 7 mi. broad), the city is one of the most spectacular in Europe, rivaling Naples and Istanbul in its wide views, the distinctive silhouette of its buildings and its enclosed situation. Round its tiled and multicoloured buildings is a belt of vines, parks, gardens and woods, broken by villas, cottages and farms.

The entrance to the fine natural harbour is protected by coastal defenses along the river mouth and on the hills behind. The climate, at its best in the autumn, is temperate (average annual

temperature 16° C [60° F], average rainfall 29.45 in.). Pop. (1960) 817,326.

Its position as the centre of government gives Lisbon the movement and vitality of a great capital. There is, however, a difference in character between its various districts. The oldest part of the city is the Alfama, or eastern district, where narrow, winding streets crowd down to the river between a jumble of houses. Alfama, the starting point of Lisbon's growth, dates from the time when the city spread beyond the walls built by the Visigoths. Its irregular layout on hilly ground, unexpected views and houses which preserve the old architectural types give it a picturesque appearance, particularly attractive to visitors. Above the Alfama towers the castle, Moorish in origin but named after St. George to commemorate the Anglo-Portuguese alliance (1386). In this area is the Sé, the Romanesque-Gothic cathedral, built in 1147 and partially destroyed by earthquakes in 1344, 1531 and 1755. It contains the tomb of St. Vincent, who was accompanied in his search for the "Sacred Headland" by two legendary ravens which form part of the city's coat of arms. The nearby monastery of São Vicente, rebuilt at the end of the 16th century by Filipe Terzi, contains the pantheon of the Portuguese kings. Other notable buildings are the church of Santo António, near the Sé, built in honour of St. Anthony of Lisbon; the ruined 16th-century palace, the Casa dos Bicos; the remains of the Moorish walls; and the façade of the Conceição (formerly Misericórdia) church. Each hill of the line running to the north is crowned by a church or monastery, and on the slopes of São Gens is the district of the Mouraria, the old quarters of the converted Saracens.

Lisbon's central district, the Baixa, was built after the 1755 earthquake and stretches from the riverbank to the old outskirts in the north. The streets are broad, geometrically aligned and broken by spacious squares, of which the most central is the Terreiro do Paço with its fine equestrian statue (1775) of Joseph I, whence its English name—Black Horse square. This square, planned by Eugénio dos Santos under the orders of the marquis de Pombal as the official entrance to the town, is approached through a triumphal arch. In Rossio square, the converging point of Lisbon's traffic, are two decorative fountains and the Dona Maria II theatre; it is also famous for its black and white mosaic, 100 yd. wide. The Baixa is the centre of Lisbon's commercial life, and in it are concentrated most of the public services.

To the west extend a number of districts, each possessing its own distinctive character, reflecting the epoch in which it was built. The most modern part of the town lies to the north. The expansion of Lisbon in this direction, begun at the end of the 18th century, took on a new impetus when the parts known as the Avenidas Novas were planned after the opening of the Avenida da Liberdade, Lisbon's most famous avenue, in 1880. Forty years

J. ALLAN CASH

THE CLOISTERS OF THE MONASTERY OF SAN JERÓNIMOS, LISBON, A FINE EXAMPLE OF THE ARCHITECTURAL STYLE KNOWN AS ARTE MANUELINA WHICH FLOURISHED IN THE EARLY 16TH CENTURY

later another great expansion took place and entirely new districts were urbanized, absorbing the small villages on the fringe of the town. The transference of various public offices there relieved traffic congestion in the Baixa; there are also such modern buildings as the airport, sports stadiums, hospitals and schools.

Despite the destruction of the great earthquake of 1755, Lisbon still has many notable old buildings. Besides those already mentioned are the Carmo church, an old 14th-century convent with pointed arches open to the sky; the Estrela Basilica, built at the request of Queen Maria I, the towers and dome of which are visible from all points; the bold Águas Livres aqueduct, built in the time of John V, which brings water from the springs north of the town into a reservoir to supply the public fountains, drinking troughs and domestic services; the 15th-century Jerónimos church, built by order of Manuel I; and the Tower of Belém, built at the same time, which stands like a sentinel at the mouth of the Tagus. The national assembly sits in an old 16th-century Benedictine convent; the same building houses the collection of national archives, called, after its original home, the Torre do Tombo collection. There are two notable palaces, the Ajuda, a richly furnished early 19th-century building, and the palace of Belém at the foot of the Ajuda slopes, the residence of the president.

There are many signs of the close bonds between Portugal and the British Isles—the British have always been the largest foreign colony after the Spaniards, and at one time there was a private quay for British ships. The Corpo Santo monastery was founded in the 17th century by Irish Dominicans; there are a Presbyterian church and an English college and, in the British cemetery, founded in 1717 and planted with cypresses, are buried Henry Fielding, the novelist, and Philip Doddridge, the Nonconformist clergyman.

Many of Lisbon's 18th-century squares contain statues; the most notable are: that of Joseph I, the Obelisco dos Restauradores, commemorating the campaign which freed Portugal from Spain; the monument to Pedro IV, who gave the country its constitutional charter, in Rossio square; and the monument (20th century) to the marquis de Pombal in the square that bears his name.

PAUL ALMASY

THE NATIONAL THEATRE OF DONA MARIA II ON THE NORTH SIDE OF ROSSIO SQUARE

In addition to the squares, which give a spaciousness to the central district, there are several parks and gardens. At the northern end of the Avenida da Liberdade is the Parque Eduardo VII, so-called to commemorate Edward VII's visit to the city. Others are the Parque Florestal at Monsanto, planted after the 1920s to protect the town from the prevailing wind; the Campo Grande, a big wooded promenade to the north; the botanical garden at Ajuda; and the zoological garden in the Parque das Laranjeiras.

One of the most interesting of many museums is the Museu dos Coches, in the old royal riding school, which possesses an unrivaled collection of state carriages, coaches, berlins, two-wheeled chaises and 17th-, 18th- and 19th-century sedan chairs. Other museums include those for ancient and modern art, archaeology, ethnology and military objects; and two municipal museums. The university, founded in 1290, was re-established in Lisbon in 1911 and a technical university was founded in 1930.

The surroundings of Lisbon form part of its charm. On both banks of the Tagus are noble country houses set in beautiful gardens. On the north bank, apart from Sintra (*q.v.*), is the 18th-century palace of Queluz, built by a French and a Portuguese architect in the style of Versailles. On the opposite bank is the 16th-century Bacalhoa, famous for its azure tiles. The coastal strip north of the Tagus from Algés to the south of Cape Roca is known as the "Portuguese Riviera" and attracts many visitors. Its centre is Estoril.

Communications, Trade and Industries.—Lisbon has four railway stations; communication with the outlying districts is by electric train. The first section of an underground railway was opened on Dec. 28, 1959, and construction was begun on an extensive system. Four escalators facilitate transportation in the most hilly districts. Between the two banks of the river, which are lined with landing stages, docks and warehouses, there is constant launch and ferry service.

Its position at the westernmost point of Europe has made Lisbon an important port of call. Its airport, Portela de Sacavém, 6½ mi. outside the town, is an intersection point for many world airlines; its estuary and fine natural harbour give anchorage for naval vessels as well as for liners and cargo ships, and it is connected by road and railway with the great European capitals and with the Portuguese hinterland. It is an important transshipping and entrepôt centre, handling about 60% of Portugal's foreign trade. Its exports are chiefly agricultural and forestry produce (olive oil, wine, fruit, cork, timber) and canned fish, especially sardines. The chief imports are coal, raw cotton, mineral oil and cereals. The city's industries include the making of chemicals, textiles, soap, pottery and paper, sugar refining, flour milling and ship repairing.

History.—The origin of Lisbon is clouded by a number of fantastic legends. The derivation of its name from the word *Olisipo* gave rise to the story that it had been founded by Ulysses; it may actually have been Phoenician in origin. During the Roman domination (205 B.C. to the 4th century A.D.) it was elevated to the dignity of a municipium by Julius Caesar and called Felicitas Julia. Occupied by the Alani, the Suebi and the Visigoths in the 5th century, it was captured by the Moors at the beginning of the 8th century and called by them Lixbuna, a name derived from an old *citania* or Roman castle on the summit of the hill on which stands the Castelo de São Jorge. Few traces remain of these successive dominations. Some stones recall Roman theatres, temples and baths; there are traces of the primitive fortifications of the Visigoths as they were modified by later invaders. Of the Moorish domination little is to be seen except the nucleus of the castle, sketches of the "Moorish Wall" and traces of agricultural customs and methods in the surrounding countryside. The city was invaded twice during the Moorish domination—by the Normans in 844 and by Alfonso VI of León in 1093—and in 1147 was captured for Christendom by Afonso Henriques after a siege lasting several months, in which he was helped by a Christian crusade including Normans, Flemish and English. In 1256 Afonso III transferred the seat of his government and court to Lisbon from Coimbra. The town, which had 15,000 inhabitants at the time of the conquest, doubled its population and extended westward. King Diniz founded the university in 1290 (transferred to Coimbra in 1537).

After the town had been besieged and burned by the Castilians in 1375, it was strengthened by additional defenses which enabled it to withstand the second Castilian invasion in 1384.

In 1390 Lisbon was made an archbishopric, and in the following centuries its importance grew with the opening of the sea route to India, the discovery of Brazil and the widespread voyages of Portuguese mariners. It became a great commercial port and the centre for the distribution of the riches of the Spanish overseas empire from 1580 to 1640. It was from Lisbon that the Invincible Armada sailed in 1588. The city's political importance was diminished during the union of the Castilian and Portuguese monarchies, but it regained its old splendour under John V.

Because it is built on rocks of Tertiary formation, Lisbon has always been subject to earthquakes, those of the 15th and 16th centuries being notably destructive. On Nov. 1, 1755, it suffered its severest shock; a great part of the town was destroyed and many thousands of people were killed. The tremor was felt throughout Europe. With valuable assistance from other countries, especially England, Portugal's oldest ally, Lisbon was reconstructed under the direction of Manuel da Maia, by order of the marquis de Pombal.

During the late 18th and early 19th centuries, political events hindered Lisbon's progress, particularly the three invasions by Napoleon's troops and the subsequent Peninsular War, in which the two rival factions at court struggled for possession of the throne. In the 20th century there was considerable development, and during World Wars I and II Lisbon was able to offer refuge to about 200,000 foreigners.

LISBOA DISTRICT is part of the province of Estremadura. Its area is 1,066 sq.mi. and its population (1960), 1,402,586. The principal occupations outside the city are agriculture and fishing, with some industries, including ironworks, on the outskirts of the capital.

LISBURN, a market town and urban district of County Antrim, N.Ire., on the Lagan river, 8 mi. S.S.W. of Belfast by road. Pop. (1961) 17,700.

Lisburn is the cathedral city of the Protestant diocese of Connor. The church, built in 1623 in "Plantation Gothic" style, was raised to cathedral status while Jeremy Taylor, the devotional writer, was bishop (1660–67). In 1627 the town was granted by Charles I to Viscount Conway, who built the castle and introduced English and Welsh settlers. The castle was besieged in 1641 during the Irish wars, and was accidentally burned down, along with the rest of the town, in 1707; the grounds are now a public park. The town served as winter quarters for the duke of Schomberg's army in 1689 before the Boyne campaign. The town and district of Lisburn became the centre of the Ulster linen industry when William III invited Samuel-Louis Crommelin and other French Huguenot refugees to settle there and establish it. Flax spinning and linen manufactures are still carried on in Lisburn, and at Lambeg, 1½ mi. toward Belfast, is a linen-bleaching centre and the Linen Research institute. The technical college was once the mansion of Sir Richard Wallace (*q.v.*), whose widow presented to the English nation the Wallace collection in London. Wallace park in Lisburn is named after him. Furniture is made at Lisburn and carpets at Finaghy nearby.

The ruins of Castle Robin, 3 mi. N. of the town, stand on the slopes of White mountain (825 ft.) and date from the 16th century. Lisnagarvey Broadcasting station, the Northern Ireland transmitter of the British Broadcasting corporation, is on Blaris moor, 2 mi. S. of Lisburn. At The Maze, 4 mi. W., is Down Royal racecourse.

LISIEUX, a town of northwestern France, capital of an *arrondissement* in the *département* of Calvados, and also capital of the district known as Pays d'Auge. It lies in the valley of the Touques river, 30 mi. E. of Caen by rail. Pop. (1962) 20,441. Most of the town's industries—brewing, machinery, plywood and

condensed milk—are included in the expanded (after Jan. 30, 1960) town area. Trade in cattle, butter, cheese and apples is also carried on.

In the time of Julius Caesar, Lisieux, under the name of Noviomagus, was the capital of the Lexovii. By the 6th century it had become one of the most important towns of Neustria; its bishopric, suppressed in 1802, dated from that period. In 911 it was included in the duchy of Normandy by the treaty of St. Clair-sur-Epte. Civil authority was exercised by the bishops, as counts of the town. In 1136 Geoffrey Plantagenet laid siege to Lisieux, which had taken the side of Stephen of Blois; it fell in 1141. There Thomas (à) Becket took refuge for a time, and some of the vestments used by him are still shown in the hospital chapel. Taken from the English by Philip Augustus, and reunited to France in 1203, the town was a frequent subject of dispute during the Hundred Years' War and later.

Because it was an important road junction, Lisieux was a target for Allied bombs in World War II. It was rebuilt on modern lines, with much wider streets, after the war. Sixteenth-century towers are all that remain of the old fortifications; most of the ancient Norman houses were burned in 1944, and of the church of St. Jacques (late 15th century) only the walls were left. St. Peter's cathedral (12th–16th century), the oldest Gothic cathedral in Normandy, is still standing.

Lisieux has become a world centre of pilgrimages to the shrine of St. Thérèse of the Child Jesus, also known as "the Little Flower of Lisieux" (see *THÉRÈSE, SAINT*). The Basilique, a massive building in the Romano-Byzantine style, dedicated to St. Thérèse, was consecrated in 1937 by Eugenio Cardinal Pacelli, later Pope Pius XII. (C. Pn.)

LISKEARD, a market town and municipal borough of Cornwall, Eng., lies 13 mi. E. of Bodmin by road. Pop. (1961) 4,492. Liskeard stands on high (400 ft.) ground 6 mi. from the sea between the deep wooded valleys of the East Looe and Seaton rivers, on the main London to Penzance railway line. The Celtic (Ilys Caer) indicates a seat of jurisdiction (as it still is) and the town was fortified, castle ruins being still visible in the 16th century. William the Conqueror gave the manor to Robert of Mortain, from whom it passed to the earls of Cornwall. Liskeard was the centre of the Cornish kings, the last of whom, King Doniert (died c. 900), lived there. Richard, earl of Cornwall, king of the Romans, created it a free borough in 1240, and vested in the burgesses nearly all the rights of a corporate town. The corporation in its modern form dates from 1586. Liskeard was one of the four Cornish stannary (tin-mining) towns. The centre of a large agricultural area, it became known for its cattle fairs, and has two markets each week; the great annual fair of St. Matthew is still held in October. The public library acquired the Leonard Courtney collection of rare Cornish books. (J. H. Pr.)

LISLE, ALICE (c. 1614–1685), whose trial and execution during the Bloody Assizes of 1685 was perhaps the most scandalous example of the perversions of justice and the savage sentences for which they are notorious, was the daughter and heiress of Sir White Beckenshaw of Ellingham, near Ringwood, Hampshire. She married (1630), as his second wife, John Lisle (d. 1664), who was later one of the judges at the trial of Charles I (1649); he became a member of Oliver Cromwell's house of lords (1657–58), for which reason his wife is sometimes known as Lady Alice Lisle. After her husband's death she lived at Moyle's court, near Ringwood.

Alice Lisle was in London during the first days of July 1685, when the rebel army of James Scott, duke of Monmouth, was at Bridgwater. She had always shown sympathy for the dissenting ministers persecuted since the restoration of Charles II and after her return to Moyle's court, she agreed (July 20) to shelter John Hickeys, a well-known Nonconformist minister. He spent the night of July 25–26 in her house, having brought with him another fugitive, Richard Nelthorpe. Both men had fought for Monmouth at the battle of Sedgemoor (July 6) and Nelthorpe was also under sentence of outlawry. Betrayed by a spying villager, both hostess and fugitives were arrested on July 26. Alice Lisle was tried before Lord Chief Justice Jeffreys at Winchester on Aug. 27, on the

capital charge of harbouring Hickeys, a traitor. She pleaded that she had no knowledge that Hickeys's offense was anything more serious than illegal preaching, that she knew nothing about Nelthorpe (whose name was not included in the indictment but was mentioned to strengthen the crown's case) and that she had no sympathy with the rebellion. Under pressure from Jeffreys the jury reluctantly found her guilty and, the law recognizing no distinction between principals and accessories in treason, she was sentenced to be burned, the penalty at that time prescribed for female traitors. A few days' respite was allowed and James II commuted the sentence to beheading; it was carried out in Winchester market place on Sept. 2, 1685. Many regarded Alice Lisle's death as judicial murder; in 1689 a private act of parliament reversed the attainder consequent upon her conviction on the ground that the prosecution was irregular and the verdict injuriously extorted by the "menaces and violences" of Jeffreys.

LISMORE, an island in the entrance to Loch Linnhe, Argyll, Scot., 5 mi. N.W. of Oban, 9½ mi. long and 1½ mi. broad. Pop. (1961) 155. It divides the lower end of the loch into two channels, the Lynn of Morvern on the west and the Lynn of Lorn on the east. The name is derived from the Gaelic *lios mòr*, "great garden," from the fertility of the soil. The shallow limestone lochs have an extremely rich vegetation. Several ruined castles stand on the coast, and the highest point is 500 ft. Steamers call at Achnacroish, and there is a ferry to Port Appin. A Columban monastery was founded in Lismore by St. Moluag about 592. About 1200 the see of Argyll was separated from Dunkeld by Bishop John, "the Englishman," and Lismore soon afterward became the seat of the bishop of Argyll. The small cathedral has been restored and is used as the parish church.

The Rev. John Macaulay, grandfather of Lord Macaulay, and the Rev. Donald M'Nicol (1735–1802), who took up the defense of the Highlands against Samuel Johnson, were ministers of Lismore. For the *Book of the Dean of Lismore*, see *SCOTTISH LITERATURE*.

LISMORE, a city of New South Wales, Austr., situated on the north arm of the Richmond river, 75 mi. from its mouth at Ballina and 20 mi. by land from that town. Pop. (1961) 18,935. Although for many years regarded as the centre of one of the richest dairying districts in New South Wales, the town has gradually developed its secondary industries. Primary industries, in addition to dairying, are pig and poultry raising; timber cutting; and corn (maize), sugar cane, vegetable, pineapple and banana growing. Secondary industries include engineering and clothing, furniture and boot and shoe manufacturing. In addition to rail transport (to Sydney and Brisbane), there is bus service between all adjoining towns on the far north coast (New South Wales), the tablelands and Brisbane. The city was named after the island of Lismore, Argyll, Scot.

LISMORE (LIOS MÓR MOCHUDA), a little market town in County Waterford, Republic of Ireland, 43 mi. W.S.W. of Waterford by rail, is situated on a hill rising steeply from the Blackwater. Pop. (1961) 810. The original name of Lismore was Maghsíath. A monastery founded there by St. Carthagh in 633 became celebrated as a seat of learning. The bishopric, said to have originated with this foundation, was united to that of Waterford in 1363. In the 9th and early 10th centuries the town was repeatedly plundered by the Norsemen, and in 978 the town and abbey were burned by the men of Ossory. Henry II received in Lismore castle the allegiance of the archbishops and bishops of Ireland. The Roman Catholic bishop of Waterford and Lismore has his seat in Waterford city. The Protestant dioceses of Waterford and Lismore were united in 1833 with those of Cashel and Emly, and the bishop of these united sees has his seat in Waterford.

The baronial castle, erected by King John in 1185, was the residence of the bishops till the 14th century. It was besieged in 1641 and 1643, and in 1645 it was partly destroyed by fire but was largely rebuilt in the 19th century. In 1581 the manor was granted to Sir Walter Raleigh and passed from him to Richard Boyle in 1602. Robert Boyle (*q.v.*), the great chemist, was born there in 1627. In 1753 the castle passed by marriage to the duke of Devonshire whose successor still retains it. On the summit of the

height is the cathedral of St. Carthagh mostly of the 17th century, with portions probably of the 12th and 13th and considerable additions in the 19th. There is some river trade and the town is the centre of a salmon fishery district.

LISSE, a town in South Holland province, Neth., situated in the centre of the flower fields between Haarlem and Leiden. Pop. (1960) 10,687. The chief industry is the growing and exporting of flower bulbs, for which there are research laboratories. A flower exposition covering about 70 ac. is held annually (March until May) at De Keukenhof, a former country estate converted into botanical gardens with hothouses and flower beds surrounded by natural woodland and dunes. Other industries are yacht building and the manufacture of agricultural appliances (including bulb-sorting machinery), wooden crates and flower boxes. Keukenhof castle (built in the 17th century, much restored in the 19th) houses a collection of old paintings and china.

LISSITZKY, EL (ELIEZER) (1890–1941), Russian abstract painter, designer and architect, was born in Smolensk, on Nov. 10, 1890. He studied engineering at Darmstadt, Ger., and returned to Russia in 1919, where he painted his first constructivist composition, "Proun No. 1." Marc Chagall then appointed Lissitzky as a teacher of art in Vitebsk. In 1921 he became professor at the state art school in Moscow, but left Russia at the end of the year when the Soviet government turned against modern art. He went to Germany first and later to Switzerland. Between 1925 and 1928 Lissitzky lived in Hanover and on request of the Landesmuseum (directed by Alexander Dörner) designed an "abstract gallery" (destroyed 1936) on entirely original principles. In the U.S. Lissitzky exhibited first in 1924 at the Société Anonyme. He was co-founder of a number of periodicals propagating the most progressive tendencies of the 1920s. In the winter of 1928–29 he returned to Moscow, where he executed his advanced constructivist ideas in official soviet exhibitions and publications for abroad. Lissitzky died in 1941.

His experiments in spatial constructions led him to devise new techniques in exhibiting, printing, photomontage and architecture, which have been of considerable influence in western Europe.

LI SSU (280?–208 B.C.), Chinese statesman, devoted a lifetime to the task of welding the warring Chinese states of his time into a single centralized bureaucratic empire, applying for this purpose the efficient but ruthless ideas of the totalitarian political philosophy known as Legalism. As minister to the ruler of the state of Ch'in, he saw his goal realized when, in 221 B.C., that monarch completed his conquest of the other Chinese states and assumed the title of Shih Huang Ti, "First Sovereign Emperor."

Li was born a commoner in the state of Ch'u (at the present Shang-ts'ai, southeastern Honan), studied under the Confucian philosopher Hsün-Tzu (q.v.), and then (247) entered Ch'in to begin almost 40 years of service under the later first emperor. For most of the radical political and cultural innovations made in the Ch'in empire after 221 (for which see SHIH HUANG TI), Li, rather than the first emperor, was primarily responsible. Most spectacular (but not most significant) was the "burning of the books" of 213, for which Li has been execrated by later scholars.

Following the first emperor's death in 210, Li became involved in the plot of the eunuch Chao Kao to void the proper succession. In 208 this eunuch turned on Li himself and had him executed at a time when the Ch'in empire was already disintegrating as the result of rebellion. Despite this tragic end to Li and his work he set a lasting imprint on Chinese history in a way that few other men succeeded in doing.

LIST, (GEORG) FRIEDRICH (1789–1846), German-American advocate of tariff protection to stimulate national in-

dustrial development, was born in industrial Reutlingen, Württemberg, on Aug. 6, 1789. Largely a self-educated man, he advanced rapidly in government service, taught briefly at Tübingen university, then rose to prominence as founder and secretary of an association of middle- and south-German industrialists favouring abolition of the tariff barriers dividing the German states. Exiled to the U.S. in 1825 for his liberal views, List encountered in Philadelphia the Hamiltonian view of national development, the "American System" of Henry Clay and the anti-Ricardianism of Henry Carey. He became editor of a newspaper in Reading, Pa., and took a keen interest in the building of canals and railroads. After becoming a naturalized U.S. citizen he returned to Germany in 1831 and three years later became U.S. consul at Leipzig.

Beginning in 1827 List advanced a qualified version of the classical theory of free trade of Adam Smith and David Ricardo. A national economy in an early state of industrialization requires tariff protection, List argued, and although protectionism entails the loss of certain immediate gains of foreign trade, this loss constitutes the equivalent of an "educational capital" invested in unfolding a nation's productive potentialities. List feared that entrepreneurs in long-established centres of industry would by unfair means of international competition prevent a young country's industrialization, thus: (1) preserving for the old countries not only markets but a flow of cheap raw materials as well; and (2) maintaining the old country's ability to accumulate capital at an accelerating rate, while retarding capital accumulation in underdeveloped areas of the world.

These persuasive arguments for tariff protection ignore the fact that although the nations of the west were politically divided they were the heirs of a basic technology of mechanized production, transportation and communication. This inheritance synchronized their economic development more closely and more harmoniously than List supposed. By contrast, economic nationalism splinters the common market and decimates the common technology. Economic nationalism in backward areas does not induce the growth of capital but disrupts the inflow of needed capital equipment and technical personnel.

The works of List, principally the *National System of Political Economy* (1909; German original, 1841), have the residual value of exposing at its roots the fallacy of generalizing into a plea for economic nationalism the occasionally relevant temporary policy of protecting "infant industries." List died by his own hand on Nov. 30, 1846, in Kufstein, Aus. After his death he was greatly honoured in Germany, where his early liberal views had made him unpopular during his lifetime.

BIBLIOGRAPHY.—Margaret E. Hirst's *Life of Friedrich List* (1909) contains a bibliography and a reprint of List's *Outlines of American Political Economy* (1827); see also H. Ritschl, *Friedrich List: Leben und Lehre* (1947); C. Brinkmann, *Friedrich List* (1949). (G. W. Z.)

LISTA Y ARAGÓN, ALBERTO (1775–1848); Spanish poet, critic and mathematician, the last important writer of the classical period, was born at Triana, a suburb of Seville, on Oct. 15, 1775. As a youth he showed unusual mathematical talent and at the age of 20 he became professor of mathematics in a nautical college in Seville. In 1807 he was appointed to the chair of rhetoric and poetry in the University of Seville. In 1813, during the French invasion, he was exiled to France, where he remained for four years, and on his return to Spain he became editor of the critical review *El Censor*. He was a founder of the Ateneo, the free university of Madrid, and his lectures there were collected under the title *Lecciones de literatura española* (1836). Lista is also remembered for his poems, especially those on sacred themes such as "A la muerte de Jesús" and "La Providencia," and for his mathematical treatise *Tratado de matemáticas puras y mixtas*. He died in Seville on Oct. 5, 1848.

LISTED SECURITIES. The two principal subdivisions of the market for outstanding securities are the securities exchanges and the over-the-counter markets. Listed securities are those that are marketed through the facilities of the exchanges. All other securities are unlisted and most of them are transferred in the over-the-counter markets. (See STOCK EXCHANGE; OVER-THE-COUNTER MARKET.)

Each securities exchange has its own set of listing requirements, those of the New York Stock exchange being the most comprehensive. A company acquires a listed status by making formal application to the exchange's department of stock list. The formal application is usually preceded by preliminary discussions to discover any obstacles to listing. The company must submit its financial statements and must divulge information concerning its history and business, properties owned, management, capitalization, and business, financial and accounting policies. The company also shows on distribution forms the number of security holders and total number of shares held in each size bracket and also the ten highest holdings of the security. The exchange prefers a wide distribution of stock, with a minimum of 1,500 stockholders. The company must have substantial assets or demonstrated earning power. It must also sign certain listing agreements requiring it to make financial statements available to the public and to perform certain acts considered to be in the interests of security holders.

The application is passed upon first by the department of stock list and then by the board of governors of the exchange. If approved, the exchange certifies this fact to the federal Securities and Exchange commission. The company then files a registration statement with the commission. Normally registration becomes effective 30 days after receipt by the commission of the registration statement and the exchange certification, and trading in the security begins on the effective date.

On the American Stock exchange (formerly the New York Curb exchange) listed and unlisted issues are traded—an exception to the general rule that unlisted issues are traded only in the over-the-counter market. Before 1934 a member of the curb exchange could request the exchange to permit trading in an unlisted issue. This is in contrast to fully listed issues, application for which is made by the issuing company. After 1934 the Securities Exchange act virtually prevented additions of unlisted issues to the stock trading list. Trading in unlisted issues accepted before that date continued but declined in importance. The New York Stock exchange, where all issues are fully listed, is so important relative to the American and other exchanges that the total volume of trading on exchanges in unlisted issues is small. In Oct. 1963, for example, securities sold on that exchange accounted for 84.6% of the market value of security sales on all U.S. exchanges.

The American Stock exchange, the National Stock exchange and other exchanges are less rigid in their requirements than is the New York Stock exchange; they are more willing to list securities of companies in a developmental stage; and most have lower listing fees.

The London Stock exchange publishes an official list of securities admitted to quotation. Companies whose securities are admitted to this list furnish about the same data as in listing on the New York Stock exchange. Financial statements are especially emphasized. A complete record of price movements from day to day is published for securities on this list. There is also published a supplementary list of securities not officially quoted. These securities are of some public interest but the companies have not complied with the rules required for entry on the official list.

When a company's securities are well-known and widely distributed, it may be advantageous to list the security and thus attract the interest of investors who insist upon purchasing only listed securities. The company may find that the price-earnings and price-dividend ratios of outstanding securities are thus increased, and the cost of funds decreased when new issues are sold. On the other hand, listing sometimes involves loss of interest on the part of over-the-counter dealers who have theretofore been making a market for the issue, with resultant decreases in price after listing has occurred.

LISTER, JOSEPH LISTER, 1ST BARON, OF LYME REGIS (1827–1912), English surgeon, who opened the modern era of surgery by introducing antiseptic surgery (the use of chemicals to

prevent surgical infections), was born at Upton, Essex, on April 5, 1827. His father, Joseph Jackson Lister (1786–1869), perfected the achromatic lens and improved the compound microscope. Joseph Lister received his M.B. at University college, London, in 1852 and in the autumn of 1853 went to Edinburgh, where he became house surgeon to James Syme. In 1856 he married Syme's eldest daughter and soon was made assistant surgeon to the Royal infirmary, where he gave his first lectures on surgery. In the following year he produced his classic paper on "The Early Stages of Inflammation," an investigation in which his interest had already been aroused by his contact with gangrene and pyemia in University college hospital, London. About the same time, he began work on the coagulation of blood, a subject related to the early stages of inflammation.

THE BETTMANN ARCHIVE

JOSEPH LISTER

After his appointment to the chair of surgery at Glasgow in 1860, Lister at first busied himself with his articles on amputation and anesthetics for Timothy Holmes' *A System of Surgery, Theoretical and Practical*. He then resumed his researches on inflammation, which took on a new meaning after his attention was drawn in 1865 to the work of Louis Pasteur (*q.v.*). Pasteur had shown that putrefaction, like other processes he called fermentations, was caused by organisms in the air. Lister at once saw that if putrefaction was caused neither by the spontaneous generation of germs nor by the oxygen in the air—two predominating theories of his day—there was some chance of preventing it. But how were the organisms in the air to be destroyed before they entered the wound? Of three possibilities, filtration, heat and chemical agents, he selected the last for experiment.

The first experiment was made in 1865 upon a compound fracture, the agent used being phenol (carbolic acid). It was applied to the wound undiluted, so as to form a dense crust with the blood. The results, after a first failure, were so satisfactory that Lister wrote two papers, entitled "On a New Method of Treating Compound Fracture, Abscess, etc." and "On the Antiseptic Principle in the Practice of Surgery," for *Lancet* in 1867. However, the caustic property of undiluted phenol made it unsuited for general surgery. It was necessary to mitigate its action by blending it with some inert substance, and the search for such a substance continued for many years. Lister found most satisfactory a mixture of crystallized phenol and shellac, which, when spread on calico and painted with a solution of gutta-percha in benzene, passed through the gutta-percha without adhering to the skin so firmly as to prevent drainage of pus.

Lister now turned his attention to the arrest of hemorrhage in wounds. It had long been the practice to employ silk or flax threads for tying arteries, long ends being left outside the wound to provide an escape route for the pus. Lister believed that the thread would not cause infection if made antiseptic and might be left with short ends that would become embedded permanently among the tissues of the wound. An extensive series of experiments led him to adopt ultimately (1880) a sulfochromic catgut ligature.

In 1869 Lister succeeded his father-in-law, Syme, in the chair of clinical surgery of Edinburgh. There his chief accomplishments were his researches in bacteriology, his substitution of the dressings of absorbent gauze for the nonabsorbing lac plaster and his attempt to provide a germ-free atmosphere in operating rooms by means of a spray of a 5% aqueous solution of phenol. The irritating properties of this spray soon led to its abandonment and replacement by asepsis, *i.e.*, scrupulous cleanliness of operating room, instruments and personnel, primarily with heat (sterilization).

In 1877 Lister accepted the chair of surgery at King's college,

London, which he held for 15 years. While there, the publication of Robert Koch's book on the etiology of infectious diseases led him to experiment with various mercurial preparations as disinfectants. In 1896 he retired from practice but not from scientific study. He was president of the Royal Society from 1895 to 1900 and president of the British Association for the Advancement of Science in 1896. In 1883 he was created a baronet and in 1897 was raised to the peerage (the first medical man so honoured) as Baron Lister of Lyme Regis. Among the coronation honours in 1902, he was nominated an original member of the new Order of Merit. He died at Walmer, Kent, on Feb. 10, 1912.

The best monument to Lister is the Lister Institute of Preventive Medicine, London—of which he was one of the founders at its inception as the British Institute of Preventive Medicine in 1891. It was modeled on the Pasteur Institute in Paris. Among Lister's contributions to general surgery, R. J. Godlee (see *Bibliography*) mentions his new amputation through the condyles of the femur, his new operation for excision of the wrist joint and for carcinoma of the breast, his improved surgery of the bladder and urethra and his introduction of such instruments as the aortic tourniquet, the wire needle, the ear hook, the sinus forceps, the urethral bougies and the forceps for extracting stones from the prostatic urethra.

LISU (LISAW, YAWYIN), a tribe inhabiting the upper Salween valley in northern Burma and parts of the Mekong valley. Reliable census data for the 1960s were not available. They count as one of the Lolo (Yi) peoples, speak a Tibeto-Burman language and are Mongoloid. Like other tribes of the Lolo group, the Lisu migrated southward from the Tibeto-Chinese borderlands apparently under Chinese pressure, and small groups of Lisu spread as far as the Shan states and northern Thailand. The Chinese distinguish between Black Lisu, White Lisu and Flowery Lisu; these terms seem to relate to the degree of assimilation to Chinese culture. In the 1960s the Black Lisu, living highest up in the Salween valley, were least civilized and wore coarse clothes of homespun hemp; the others dressed in colourful and elaborate garments. In all their migrations the Lisu kept to the higher parts of hill ranges, where conditions favour the cultivation of such dry crops as hill rice, maize (corn) and buckwheat on frequently shifted fields worked mainly with hoes. Cattle are kept for the sale of meat only; houses are constructed of wood and bamboo. Dress, ornaments, weapons and implements show the influence of Chinese, as well as Tibetan, culture. Crossbows, with poisoned arrows, and dogs are used for hunting. Little is known of Lisu social organization, except that they are divided into exogamous clans, many of which are named after animals. They worship their ancestors as well as such deities as gods of earth and sky, wind, lightning and forest. Their feasts include dancing to the music of reed pipes, in which both sexes join; marriage is preceded by open courtship. The dead are burned in coffins, and there are detailed instructions regarding the path to the land of the departed ancestors. For three years after the funeral, offerings are regularly made for deceased kinsmen.

(C. v. F.-H.)

LISZT, FRANZ (FERENCZ) (1811–1886), Hungarian composer, piano virtuoso and piano teacher, was born on Oct. 22, 1811, at Raiding, near Sopron, Hungary. His father, Adam Liszt, a steward serving the Esterházy family, was Hungarian (according to the son); his mother, Anna Lager, was Austrian. An able amateur pianist, Adam recognized his son's precocious talent and brought it to the attention of his employer and other Hungarian magnates. In 1820, impressed by the young Liszt's playing, a

group of noblemen pledged him an annual subsidy, thus enabling the family to move to Vienna, where Franz studied the piano with Karl Czerny and harmony with Antonio Salieri. On April 13, 1823, he played at a concert that perhaps was attended by Beethoven.

Taken to Paris the same year, he continued to study under Ferdinando Paër and Anton Reicha. His astonishing ability and personal charm made him the darling of society. During the next

THE BETTMANN ARCHIVE

FRANZ LISZT. PHOTOGRAPHED c. 1830

four years young Liszt and his father traveled in France and made several journeys to England. His repertory included the technically exacting concertos of J. N. Hummel and improvisations on submitted themes. His sensitive nature occasionally allowed him to yield to moodiness and mysticism, and at about this time he had the ambition to become a priest. Exhibited as a second Mozart he was encouraged to compose his youthful works, including a one-act opera, *Don Sanche*, written with the help of Paër and probably Rodolphe Kreutzer and produced at the Paris Opéra on Oct. 17, 1825. In 1827 Adam Liszt died at Boulogne-sur-Mer

and his son was thrown upon his own resources. He settled in Paris with his mother, who established a comfortable home, Liszt being obliged to give piano lessons.

Though easily disturbed emotionally, young Liszt had a lively curiosity. He read widely and became interested in the socialist doctrines of Saint Simonism. Between 1830 and 1832 he encountered three figures who strongly influenced his development: Berlioz, Paganini and Chopin. The technical virtuosity of Paganini inspired Liszt's keyboard experiments, and within a short time he had vastly increased the range of his piano technique. Berlioz and Chopin deepened his conceptions of musical expression, eventually leading to the style of his later years.

Closely associated with the romantic authors as well as the musicians of his time, Liszt led an agitated life. In 1834 he formed a liaison with the countess Marie d'Agoult (q.v.), who bore him three children within five years. The second child, Cosima, became the wife of Hans von Bülow and later of Wagner. The attachment lasted for a decade, but its intensity had subsided before the final parting. Ostracized by society, they lived first in Geneva, then briefly in France and later traveled in Italy, where they studied the art and literature of the Renaissance. In the spring of 1838 Liszt gave several concerts in Vienna for the benefit of Hungarian flood victims, setting an example of philanthropic generosity.

Supreme as a pianist (he had vanquished his one serious rival, Sigismond Thalberg), he nevertheless found himself encumbered by mistress and children, from whom temporary separations became necessary. From 1839 to 1847 he journeyed all over Europe, exciting extravagant praise and adulation. Besides setting new standards of piano playing he established the vogue of the solo piano recital and also elevated the social position of the performing artist.

Liszt made his last tour as concert pianist in 1847. In Russia he met Princess Carolyne von Sayn Wittgenstein, a woman of cultural and intellectual distinction to whom he was strongly drawn. In 1848 they settled in Weimar, where Liszt held a position of great influence. Arranging and conducting concerts and operas in this small German city, he established it as a centre of artistic progress recalling its brilliant period under the influence of Goethe and Schiller. At Weimar he not only wrote and performed his most important orchestral works but also performed many works of other composers. The neo-German party, revolving around the personality and genius of Liszt, propagated a "music of the future" and brought together artists for the express purpose

of performing deserving works without regard to their immediate success. In all, 20 operas were given their premier performance or were revived at Weimar. In 1849 he gave *Tannhäuser* and in the following year the first performance of *Lohengrin*. Important works of Berlioz, with whose music Liszt felt a particular affinity, and Schumann were also heard at Weimar; and Schubert's opera *Alfonso und Estrella* received its first performance (1854) as a result of Liszt's initiative.

The neo-German school was not without its detractors, however. Johannes Brahms's attitude was definitely antipathetical to the philosophy of Liszt and his followers, who perceived an extra-musical poetic content in their art. Brahms saw himself the inheritor of a glorious musical past and refused to recognize that music could be conceived in any terms other than musical. Brahms's attack protesting the influence of the neo-German school did little to further his cause and it actually subjected him to the life-long ridicule of the "futurists."

After 13 years at Weimar the pattern of Liszt's life changed. Reaction and opposition to the production of Peter Cornelius' opera *Der Barbier von Bagdad* led in 1858 to Liszt's resigning his official position with the Weimar opera, although he remained in the city and continued to conduct for three more years. Then he followed the princess to Rome, expecting to marry her on his 50th birthday. In 1865, when the plan had failed through the refusal of the church to sanction her divorce, he took minor orders. A withdrawal from the world, however, was far from his thoughts. He resumed his piano classes in Weimar in 1869 and in 1875 became director of the newly opened academy of music in Budapest.

For some years Liszt divided his time between the Hungarian capital, Rome and Weimar, winning great admiration and esteem. He died at Bayreuth, July 31, 1886, while attending a Wagner festival.

Liszt's music can be divided into four broad categories: piano, orchestral works, choral works and songs. As a composer of piano music he was a pioneer. His youthful pieces showed talent but his individuality emerged only after he was able to use his transcendental technique creatively. The brilliant scale passages, arpeggios and "blind octaves" of the *Études d'Exécution Transcendantes* were not only intended for virtuoso exhibition; they provided a background of orchestral associations against which the main themes stood out in powerful chords or long, sustained melodies. Other piano works are remarkable for their chromatic harmony while the Sonata shows the use of theme transformation. His melodies and harmonies are often sentimental in character, but he compensates for this by his imagination and his astonishing flashes of originality. His last piano works show an inquiring mind ready to lead music far into the future. The harmonies of "Nuages gris," "La Lugubre Gondole" and the third "Mephisto Waltz" look forward to Debussy and Bartók. In his "Hungarian Rhapsodies" Liszt tried to reflect the soul of his native land. He succeeded admirably, despite the limited knowledge at this time of Hungarian folk music, which led him to place too great a value on the contribution of gypsy music and to underestimate the older native Hungarian musical tradition. Later generations have reversed the evaluation (due particularly to the researches and influence of Béla Bartók and Zoltán Kodály) and have judged Liszt's works to be superficial. He was a supreme transcriber and arranger for the piano of songs, symphonies and operatic extracts, and his numerous arrangements did much to further the cause of the music of Beethoven, Schubert and Berlioz.

His life and work illuminate the romantic musical movement. Influenced by Berlioz' *Symphonie Fantastique*, and developing the 19th-century idea of program music, his orchestral works made a strong pictorial appeal. He was the originator of the symphonic poem, his 13 examples of this form illustrating a dramatic character, the personality of a poet, a myth, a patriotic scene, a scene from nature, a painting and a poem. They can be easily apprehended, however, without the aid of a literary synopsis. The *Faust* (1854-57) and *Dante* (1855-56) symphonies are elaborations of the symphonic poem principle and present Liszt's vision of the three main characters in Goethe's *Faust* and of Dante's *Inferno* and *Purgatorio*.

Among Liszt's choral compositions, which include Masses, psalms and part songs, are two unfortunately neglected oratorios: *Die Legende von der heiligen Elisabeth* (1857-62) and *Christus* (1855-67). The *Via Crucis* (1878-79) is remarkable for its harmonies; *Die Glocken des Strassburger Münsters* (1874) experiments with musical prosody. Liszt's solo songs (about 75) are also little known. Many of them have a simple, lyrical quality; others are boldly dramatic. Among the organ works are the Fantasy and Fugue on *Ad nos, ad salutarem undam* (1850) and the Prelude and Fugue on the letters of Bach's name (1855). These, too, are conceived in a romantic organ style and are notable for their impressive climaxes.

Liszt's collected writings were published in *Gesammelte Schriften*, edited by L. Ramann, six volumes (1880-83). A large number of his letters were published in German in *Liszt's Briefe*, edited by La Mara, eight volumes (1893-1904). Other volumes of Liszt's correspondence were later published in German, French and English.

LISZT, FRANZ VON (1851-1919), German jurist and an outstanding figure in the history of criminal law and criminology. Liszt was born on March 2, 1851, in Vienna, his father being the procurator-general at the Austrian supreme court; an elder cousin was the composer Franz Liszt. After studying at the University of Vienna under Rudolf von Jhering (*q.v.*) and at Göttingen and Heidelberg, Liszt became a professor at Giessen in 1879, moved to Marburg in 1889 and finally to Berlin in 1899, where he remained until his retirement in 1916.

Liszt was distinguished both as a systematic expositor and as a critic of the theory and purpose of the criminal law. As an expositor, his most famous work is *Lehrbuch des deutschen Strafrechts* (1881). The tone of Liszt's critical work was set in his "Marburg program" (*Der Zweckgedanke im Strafrecht*, 1882), in which he applied to criminal law Jhering's insistence on the sociological purpose of law in general. Liszt emphasized the dual aim of the criminal law of protecting society and of providing the maximum of legal certainty, seeking the practical application of these ideas by the inductive methods of the natural sciences. He opposed short prison sentences but favoured the raising of the age of criminal capacity and sentences of fixed duration in special prisons for young offenders; he defended capital punishment and long periods of preventive detention for the habitual criminal.

Of wide culture and international interests, Liszt was a co-founder in 1889 of the *Internationale Kriminalistische Vereinigung*, made an important contribution to comparative criminal law (*Die Strafgesetzgebung der Gegenwart*, 1894-99; *Vergleichende Darstellung des deutschen und ausländischen Strafrechts*, 16 vol., 1904-09) and wrote a leading textbook on international law. Beginning as an admirer of Bismarck, he became a liberal of the left and at the time of his death looked forward to the rebuilding of international co-operation, particularly in the field of criminal science. He died on June 21, 1919, at Seeheim an der Bergstrasse.

LITANY (Gr. "prayer") in Christian liturgies is a form of alternating prayer in which the minister bids invocations or petitions, to each of which the worshipers answer with short, often repeated responses of a type akin to acclamations. The form probably derives from Jewish synagogue prayers and responsive psalmody; *e.g.*, Ps. cxviii and cxxxvi, and the apocryphal Song of the Three Children. Analogous forms were employed in pagan worship—*cf.* the invocations of Isis (as given in the Oxyrhynchus Papyri), and the prayer taught Licinius' troops at the battle of Campus Egerius, May 313 (quoted in Lactantius, *De morte pers.*,

xlvi). The response *Kyrie eleison* ("Lord, have mercy"), common in Christian litanies, was also a frequent cry of pagan prayer (Epictetus, *Discourses*, ii, 7).

The oldest identifiable Christian litanies stem from Eastern churches of the 4th century. Basil referred to their recent introduction in a letter to the clergy of Neocaesarea. At Antioch, litanies led by a deacon at the dismissal of catechumens and penitents, and at the prayers of the faithful before the offertory, are attested by the Apostolic Constitutions (book viii) and the sermons of John Chrysostom. The customary response was *Kyrie eleison*. These diaconal litanies became a distinctive feature of all Eastern liturgies. The Byzantine liturgies of St. Basil and St. Chrysostom contain seven: at the beginning of the rite, after the Gospel, at the dismissal, before and after the offertory, before the Lord's Prayer and after communion. Chrysostom at Antioch, and the Gallic pilgrim Etheria in Jerusalem (c. 395), have recorded the use of similar litanies also at the daily offices of matins and vespers.

The Western Latin liturgies soon adapted to their use litanies of the Eastern type. A *Deprecatio* ascribed to Pope Gelasius I (492-496) and preserved in the works of Alcuin, was possibly introduced by that pope at the beginning of the Mass. But by the time of Gregory I (590-604), at ordinary Masses, only the *Kyrie eleison* responses, alternating with *Christe eleison*, were in use; and since Gregory's day the full litany form has been lost from the Mass altogether. In the rite of Milan, however, a comparable litany survives at the beginning of the liturgy on the Sundays of Lent. The Gallican Council of Vaison (529) ordered the *Kyrie eleison* to be sung at all Masses and at the offices of matins and vespers, "as is the custom of the apostolic see and also throughout the whole East and the provinces of Italy." The Stowe missal (Irish, 8th century) contains a litany before the Gospel lesson that is undoubtedly borrowed from the East—cf. the petition for "the most pious emperors and all the Roman army." St. Benedict in his monastic Rule enjoined a litany at matins and vespers immediately before the concluding Lord's Prayer, and the recital of *Kyrie eleison* at the end of the other daily offices. From the same period, the Gelasian sacramentary directs "*Kyrie eleison* with litany" in all major rites of ordination.

Peculiar to Western custom were litanies sung in procession on special occasions of penitence and fast—adaptations of pagan *Ambarvalia* (q.v.) processions about the land to purify and protect crops. They are first heard of in Gaul c. 470, when Bishop Mamertus of Vienne instituted such litany processions on the three days before Ascension day, to invoke the blessing of favourable weather and fruitful seasons. Called rogations, these processions were enjoined upon all Frankish Gaul by the Council of Orléans (511). Some time in the 6th century, the Roman church instituted a similar processional litany (the *litanía maior*) on April 25, to replace the pagan Robigalia. The Gallican rogations before Ascension (the *litaníae minores*) were adopted at Rome by Leo III (795-816). In Spain, rogation processions at sowing time were inaugurated in Pentecost week and at the autumn equinox, and also at the beginning of the Gallican Advent season in early November (Council of Gerona, 517; Isidore of Seville, *De officiis*, i, 39-40). The Benedictine missionaries to the Anglo-Saxons entered Canterbury in 597 singing the rogation day litanies (Bede, *Ecclesiastical History*, i, 25); and the English synod of Cloveshoe (747) ordered litanies on April 25 "after the manner of the Roman church" and on the pre-Ascension days "after the manner of our ancestors." (See also BOUNDS, BEATING THE; PROCESSION.)

Another type of litany originating in the East was introduced at Rome in the 7th century—one made up of invocations to the Trinity, the angels and the saints—and was combined with the petitionary rogation-type litany. It was employed at processions before papal Masses on Ash Wednesday, the Ember days and four chief festivals of the Virgin Mary. Their development is commonly attributed to a Syrian pope, Sergius I (687-701). The Irish and Anglo-Saxons cultivated this type of litany especially and spread its use in their missions on the continent.

The Roman litany, as it has historically developed, is still sung in procession on Easter Even after the benediction of the font and before Mass. In the breviary of Pius V it is recited after

lauds on nonfestal weekdays of Lent, rogation days and April 23. The litany consists of (1) invocations to the Trinity (response: *Kyrie eleison*) and to the angels and saints (response: "Pray for us"); (2) deprecations or prayers for deliverance from all evils, and obsecrations or entreaties by virtue of Christ's atoning work (response: "Deliver us, O Lord"); (3) intercessions (response: "We beseech thee to hear us"); and (4) concluding devotions to Christ as Lamb of God, and the *Kyrie eleison*.

At the Reformation, Martin Luther issued (1529) both Latin and German revisions of the Roman litany, eliminating all invocations of saints. A similar vernacular revision of singular literary finesse, made for the Church of England by Archbishop Thomas Cranmer, was published in 1544. The English litany has been incorporated in all editions of the Book of Common Prayer since 1549. Its traditional use is after Morning Prayer on Sundays, Wednesdays and Fridays; but it is also a common custom in Anglican churches to sing the litany in procession before the Holy Communion and on the rogation days.

LITCHI (LYCHEE; also spelled lichi, leechée, etc.), the fruit of *Litchi chinensis*, a tree of the family Sapindaceae, believed to be native to southern China and adjacent regions. It has been the favourite fruit of the Cantonese since ancient times; neither the orange nor the peach is held to equal it. Its introduction into the western world, however, came relatively late. It is recorded to have reached Jamaica in 1775.

The first litchi fruits to mature in Florida—where the tree has attained commercial importance—are said to have ripened in 1916. A few trees introduced into California in the 19th century have occasionally produced fruits but, in general, conditions there are apparently unfavourable for their successful establishment. Around the Mediterranean are a few bearing trees; in South Africa a small horticultural industry is based upon litchi production. The tree is cultivated in numerous parts of India and has received horticultural attention in the Hawaiian Islands. Occasional trees are to be seen in tropical America.

The litchi will tolerate about as much cold as the orange. It does not produce good crops in climates which are hot and humid throughout the year. The tree must be subjected to a period of cold weather annually or, failing this, a long dry season. In short, something must discourage vegetative growth and induce flowering. Even at best, the litchi has a strong tendency toward alternate or irregular production.

The tree is a handsome one, developing a compact crown of bright green foliage, beautiful the year round. The leaves are compound, composed of two to four pairs of elliptic to lanceolate leaflets two to three inches long. The flowers, small and inconspicuous, are borne in terminal panicles sometimes a foot in length. The fruits, which are produced in clusters, are oval to round, strawberry-red in colour and an inch or slightly more in diameter. The brittle outer covering encloses white, translucent watery flesh and one large seed. The flavour is subacid, sprightly, delicious, suggesting that of a Muscat grape. The fruit is eaten fresh, canned or dried, as the litchi nut of commerce.

About 50 varieties have been described from southern China, of which No Mai and Haak Ip are considered to be among the best. In Florida the Brewster, from Fukien province in China, has attained commercial importance; Groff, a Hawaiian production, and Bengal, from India (where there are several varieties), are considered excellent. In South Africa the most important commercial litchi is one which had its origin in Mauritius.

The tree is propagated by seed and by air layering. When moved to the permanent orchard, litchi are set 25 to 35 ft. apart. They require very little pruning and no unusual cultural attention, though they should have abundant moisture around the roots most of the time. The trees come into production at three to five years of age. (W. Po.)

LITERARY FORGERY. A forgery is essentially a piece of work created or modified with an intention to deceive. This

definition excludes from the category of literary forgeries both the copy made in good faith for purposes of study and the large class of writings that, in the course of their descent from antiquity, have become associated with the name of some great classical author or Father of the Church. A good example is the Pauline commentaries of the heretic Pelagius, which have been transmitted under the name of St. Jerome, one of his most bitter opponents.

Nevertheless, these exclusions made, there remains a heterogeneous collection of forged writings, proceeding from a variety of motives on the part of their authors. Certain broad divisions are possible: works produced to exalt or denigrate some religion, political party or race; works produced pseudonymously by an author who despairs of obtaining recognition under his own name, or who considers that he has been unjustly neglected and takes vicarious pleasure in hearing his forgeries lauded by the very critics who rejected his genuine writings; forgeries whose motive is financial; and forgeries produced as hoaxes.

Forgery to Further a Cause.—This category includes various pseudonymous apocryphal scriptures (see M. R. James, *The Apocryphal New Testament*, 1953); spurious letters, such as those attributed to Pontius Pilate, the creation of which began in the early centuries of the Christian church and has continued to modern times (see E. J. Goodspeed, *Strange New Gospels*, pp. 42–62, 1931); or the Epistle of Lentulus, which provides a description of Christ's personal appearance that has inspired many artists. To these may be added the great ecclesiastical forgeries, the Donation of Constantine (*q.v.*) and the False Decretals of Pseudo-Isidore (see *DECRETALS, FALSE*), which powerfully influenced the consolidation of the temporal authority of the popes during the later middle ages. Similar in character are the forged charters that sometimes emanated from medieval monasteries, either to defend a traditional right that had been called into question or, less defensibly, to extend the territorial holdings or the privileges of a religious house (see Joan C. Lancaster, "The Coventry Forged Charters," in *Bulletin of the Institute of Historical Research*, xxvii, 1954). In contrast, as an example of forgeries designed to damage the reputation of a religion or a community, may be mentioned the notorious *Protocols of the Learned Elders of Zion*, a fabrication made in tsarist Russia purporting to be evidence of a Jewish conspiracy to obtain world domination, which has been often appealed to by anti-Semitic movements to justify persecution (see *ANTI-SEMITISM*).

Forgery to Gain Recognition.—No forgery of this type is more famous than the "Thomas Rowley" poems of Thomas Chatterton (*q.v.*), which the youthful author attempted to pass off as the work of a medieval cleric. Chatterton, however, enjoys a place in English letters as a creative genius in his own right, and is far removed from the more conventional forger William Ireland (*q.v.*), who cheerfully manufactured Shakespearean documents until nemesis overtook him and the "lost" tragedy *Vortigern* was laughed off the stage at the Drury Lane theatre in 1796. More fortunate was Charles Bertram, who produced an account of Roman Britain by "Richard of Westminster," an imaginary monk whom Bertram's dupe, the eccentric antiquary Dr. William Stukeley, identified with the chronicler Richard of Cirencester, known to have resided at Westminster in the 14th century. The influence of Bertram's forgery (cunningly published in a volume containing the works of two genuine ancient authors, Gildas and Nennius) upon historians of Roman Britain has been enormous, and lasted into the 20th century. Equally effective, though in a somewhat different fashion, were the Ossianic poems of James Macpherson (*q.v.*), which influenced the early period of the Romantic movement. To what degree Macpherson's poems are to be regarded as spurious is not certain. Denounced in his own day, it remains possible that they were, as he claimed, based upon a genuine oral tradition of Scottish Gaelic poetry; but there can be little doubt that they were carefully edited and interpolated by their collector.

Forgery for Financial Gain.—Of all types of forgery, this is the most common, though this fact does not exclude other, less materialistic considerations from the mind of the most venal author. However, in the numerous forged autographs that appear on the market, it is difficult to see any motive but self-enrichment.

Little ingenuity is required, apart from a capacity to imitate another's hand and style in a letter, poem or other short document. Occasionally a forger appears with a certain specious glamour like Constantine Simonides (1824–67), the Greek adventurer who varied his trade in perfectly genuine manuscripts with the sale of strange concoctions of his own; or Maj. George de Luna Byron, alias De Gibley, who claimed to be a natural son of the poet Byron by a Spanish countess, and who successfully produced and disposed of large quantities of forgeries ascribed to his alleged father, to Shelley, Keats and others (see T. G. Ehrsam, *Major Byron*, 1951). More commonplace is the Edinburgh forger A. H. ("Antique") Smith, who was responsible for forgeries of Robert Burns, Sir Walter Scott, Mary Stuart and other characters from Scottish history—a feat that ultimately earned him 12 months' imprisonment (see W. Roughhead, *The Riddle of the Ruthvens*, 1936).

More recent and more notorious was the case of the Wise forgeries. Thomas James Wise (1859–1937) was one of the most distinguished private book collectors on either side of the Atlantic, and his Ashley library in London became a place of pilgrimage for scholars from Britain, Europe and the United States. He constantly exposed piracies and forgeries and always denied that he was a dealer. The shock was, accordingly, the greater in 1934 when John W. Carter and Henry Graham Pollard published *An Enquiry Into the Nature of Certain Nineteenth Century Pamphlets*, proving that about 40 or 50 of these, commanding high prices, were forgeries, and that all could be traced back to Wise. Subsequent research has served only to confirm the finding of Carter and Pollard and to convict Wise of other, and more serious, offenses, including the sophistication of many of his own copies of early printed books with leaves stolen from copies in the British museum.

Forgery as a Hoax.—Many persons derive pleasure from the idea of deceiving the expert and making him look foolish. An example of this would be George Psalmanazar (1679?–1763), a Frenchman who went to England, pretending, with great success, to be a native of Formosa, and published a book about that island, which he had never visited. Another case is William Lauder, who attempted to prove Milton guilty of plagiarism by quoting modern Latin poets, into whose works he had interpolated Latin translations from *Paradise Lost*. Less pardonable is the mentality that abuses the faith of simple people by fabricating a document that appears to confirm their religious beliefs, so that disillusionment, when it comes, is the more bitter. This was the case with the so-called *Cidade Calenlixness* or *Dialogue of Jesus and John*, a text allegedly in a papyrus in the British museum, which purports to be a discussion between Jesus and John, strikingly confirming the Christian Scientist teachings of Mary Baker Eddy, but which is actually a conflation of genuine ancient materials and modern fabrications. It has been printed in popular magazines and enjoys a wide circulation, particularly in the United States. More innocent is the forgery made as a joke but taken seriously. An example of this is provided by the "Ern Malley" poems, offered to an Australian magazine in 1944 as the work of a recently dead poet, but actually composed by two young soldiers who wished to ridicule certain aspects of contemporary poetry.

The Detection of Literary Forgeries.—This may be done by scientific examination, by the external criticism of paleography and diplomatic, and by methods of textual criticism.

The scientific examination of the materials of a forged document may demonstrate its spurious character by showing that the parchment, paper or ink cannot belong to the period to which they pretend. However, a skilful forger takes care to secure appropriate materials; and in any case, scientific examination will not avail against the contemporary forger, living in the same age as his victim. Accordingly, other tests must be employed.

Forgeries may be detected by the methods of examination formulated by Jean Mabillon in his great work, *De re diplomatica* (1681), for determining the authenticity of a document by the writing and the style of the terminology. These techniques have developed during three centuries into the modern sciences of paleography and diplomatic (*qq.v.*), by which various scripts and formulas can be assigned to particular ages and localities, and

effective comparison can be made between two examples of handwriting purporting to come from the same pen. Thus it is possible to state that a particular document could not have been written at the date that it bears (*see* B. Schofield, "The Lane Bequest," in *British Museum Quarterly*, xi, pp. 73-76, 1937). In dealing with printed texts, analogous methods are employed.

Nevertheless, a forgery may pretend to be no more than a copy of a genuine original. It then becomes necessary to examine the language and style in which it is written and to look for anachronisms or for statements that conflict with known authorities. This is the method of textual criticism brilliantly employed by Richard Bentley (*q.v.*) in his *Dissertation on the Epistles of Phalaris* (1699), which proved that these letters, far from being written by a Sicilian tyrant of the 6th century B.C., were, in fact, the work of a Greek sophist of the 2nd century A.D. Similarly, Sir George Warner, giving evidence at the trial of A. H. Smith (*see above*), was able to show that several of the forgeries contained errors of dating, quite apart from the fact that Smith's efforts to imitate the writing of many of his subjects were not very convincing.

While the detection of the learned and careful forger may require an expert, the general level of forged literary autographs is a low one, and they can often be detected by anyone taking the trouble to compare them with an authentic example. Many collectors have been deceived by their own credulity, because they wished to believe that they were getting a good bargain and subconsciously suppressed their critical faculty. A classic case is that of the French forger Vrain-Denis Lucas, who sold to Michel Chasles a collection of forgeries including a letter of St. Mary Magdalene, written in French on paper made in France! (*See* M. E. Charavay, *Faux Autographes. Affaire Vrain Lucas*, 1870.) A good knowledge of the general literary and historical background of documents; familiarity with genuine examples of handwriting gained either from facsimiles or, better still, from originals in libraries and museums; and plain common sense are excellent protection against serious deception.

LITERATURE (ARTICLES ON). *Encyclopædia Britannica's* articles on national literatures comprise a world-wide survey, discussing the evolution of each literature, the works associated with its historic movements and its recent tendencies. In addition to major outlines such as AMERICAN LITERATURE; DUTCH LITERATURE; ENGLISH LITERATURE; FRENCH LITERATURE; GERMAN LITERATURE; ITALIAN LITERATURE; RUSSIAN LITERATURE; SPANISH LITERATURE; THAI LITERATURE; etc., the literatures of many smaller nations are treated—for example, Bulgarian, Burmese, Ethiopian, Hungarian, Icelandic and Yugoslav literature. Portuguese-American and Spanish-American literatures are outlined in IBERO-AMERICAN LITERATURE.

Many authors whose contributions are summarized in the national surveys are discussed also in biographical articles. These range from detailed studies of such world figures as Cervantes, Goethe, Molière and Shakespeare to brief sketches of authors whose work has been nationally treasured but not widely translated. Of related interest are the articles on groups—for example, PRE-RAPHAELITE BROTHERHOOD; BLOOMSBURY GROUP—and the article ROMANTICISM.

PROSE provides cross references to the various articles dealing with prose literature, a form of composition which lagged far behind verse in its development as a literary art. STYLE, LITERARY discusses the leading schools of thought, past and present, as to the qualities that constitute good writing. Related articles include FIGURES OF SPEECH and RHETORIC. The most potent of all influences on English style is discussed in BIBLE, TRANSLATIONS OF.

POETRY discusses the elusive question of what constitutes a poem; a closely related article is POETIC IMAGERY. VERSE describes the patterns of rhythm that enter into the construction of metrical forms. Among supplementary articles are BALLAD, BLANK VERSE; ELEGY; EPIC POETRY; FOLK MUSIC; FOLK SONG, U.S.; METRE; RHYME; SONG, etc.; articles on individual verse forms—for example, BALLADE; RONDEAU; SESTINA; SONNET; TRIOLET; VILLANELLE; articles on types of metrical foot—ANAPÆST; DACTYL; IAMB; TROCHEE; and articles on types of metrical line—HEXAMETER, etc. For ancient Greek metre *see* PROSODY CLASSICAL.

NOVEL outlines the history and major variations of this form of storytelling, and the work of the great exponents of each genre. Supplementary articles include PICARESQUE NOVEL, THE; ROMANCE. SHORT STORY traces the origins of the modern short story and its rapid evolution in the 19th and 20th centuries.

DRAMA is devoted primarily to the history of drama as a literary form; for the history of dramatic performance *see* THEATRE. Discussions of drama are included also in the articles on national literatures, and related articles are cited in THEATRE (ARTICLES ON). There are also articles on COMEDY; TRAGEDY; MELODRAMA.

Related to all the foregoing genres are the article FOLKLORE; separate articles on many folk and legendary figures important in literature, for example, FAUST; and such articles as ARTHURIAN LEGEND and CHARLEMAGNE LEGENDS.

Major works of literature are discussed in the biography of the author. Works of unknown or multiple authorship are frequently the subject of separate articles; *see*, for example, ANGLO-SAXON CHRONICLE; BEOWULF; REYNARD THE FOX.

BIOGRAPHY describes the world's great works in this field and the varied approaches, from uncritical gossip to Freudian analysis, that have been made to the problem of bringing character into clear focus. A related article is AUTOBIOGRAPHY.

Additional articles on literary genres include CHILDREN'S LITERATURE; ESSAY; HUMOUR; JOURNALISM; LIGHT VERSE; MYSTERY AND DETECTIVE STORIES; ORATORY; PARODY; PASTORAL; PROVERB; RIDDLE; SATIRE; SCIENCE FICTION.

The history and contemporary methods of book publication are discussed in PUBLISHING. Among other articles on media of the printed word are BOOK; LITTLE MAGAZINE; NEWSPAPER; PERIODICAL. An article of related interest is LITERATURE, SOCIETIES OF.

Among the articles in which great literatures of antiquity are described are CLASSICAL SCHOLARSHIP; GREEK LITERATURE; LATIN LITERATURE; SANSKRIT LITERATURE.

BIBLIOGRAPHY discusses the classification of books according to subject matter, locale, era, etc.; the identification of specific printings; and related questions, such as the methods of detection used for the separation of authentic texts from corrupt ones. Articles relevant to this topic include BOOK COLLECTING; ILLUMINATED MANUSCRIPTS; INCUNABULA; INFORMATION PROCESSING; LIBRARY; LITERARY FORGERY; PALEOGRAPHY; TEXTUAL CRITICISM. Articles on reference works include ATLAS; CONCORDANCE; DICTIONARY; ENCYCLOPÆDIA.

The sections of AESTHETICS dealing with criteria of beauty in literature are supplemented by CRITICISM and DRAMATIC CRITICISM. *See also* AESTHETICS, HISTORY OF.

Important phases of literature that are treated in over-all perspective in the articles cited above are covered in specialized studies in articles cited in HISTORY (ARTICLES ON) and PHILOSOPHY (ARTICLES ON).

See the Index for more comprehensive lists of articles and sections of articles dealing with each topic.

LITERATURE, SOCIETIES OF. Literary societies may be divided into three main kinds: the academy, established as an arbiter of literary taste and linguistic correctness; the club, a fellowship of authors or patrons to further individual or collective creative work; and the learned society of letters, an organization devoted to literary criticism and scholarship.

Academies.—The academy is best exemplified by the Académie Française founded by Cardinal Richelieu in 1635. Its functions were to include criticism of authors' works (but only at their own request) and the compilation of a French dictionary, together

with the general purposes of establishing canons of literary taste and facilitating the correct growth of the vernacular. Membership has always been limited to 40, and the Académie numbers among its members most notable contemporary men of letters, although this has not always been the case. It also distributes several literary prizes. A similar function was first performed in Germany by the Fruchtbearbende Gesellschaft (1617), and in Spain by the Real Academia Española (1714). Most Italian cities have literary academies, the most important of which are the Accademia della Crusca (1552) of Florence, and the Accademia dell'Arcadia (1690) of Rome.

England had the makings of an academy as early as 1572 when Matthew Parker, archbishop of Canterbury, founded the Assembly of Antiquaries which included William Camden, William Lambard, Sir Robert Cotton and John Stow among its members. Although mainly concerned with history and archaeology this society also published several Anglo-Saxon texts and was the first instance of a society serving the purposes of philological scholarship to an important degree. In 1616–17 Edmund Bolton took a step further and, had his proposal for a formal literary academy not been thwarted by the death of James I, England would have preceded France in establishing an academy claiming royal favour. The establishment of the Académie Française brought a demand for an English equivalent but, although projects came from Thomas Sprat, John Dryden, Daniel Defoe, Joseph Addison, Jonathan Swift and others, none came to fruition. However, the Royal Society of Edinburgh (1783) had a strong "literary class" of which Sir Walter Scott was president from 1820 to 1832.

The British Academy (1901), like the American Academy of Arts and Letters (1904), has never held the same status or claimed the same powers as its French counterpart. It was founded mainly to provide a British representative on the newly formed International Association of Academies. Its literature section comprises 40 members and its *Proceedings*, which began to be published in 1903, include the texts of the lectures which are a regular feature of its activities. (See also ACADEMIES.)

Clubs.—Literary clubs have generally been short-lived unions unable to survive the original members or even the original members' personal squabbles. Many of the 18th-century clubs in England, however, made important contributions to literature either by their patronage or by their own discussions and the ideas which arose out of them. The two most important clubs of the former type were the Kit-Kat club, the members of which were active playgoers and patrons of the drama, and were probably responsible for the building of the Haymarket theatre in 1705; and the Brothers club, a Tory group which numbered Swift, John Arbuthnot and Matthew Prior among its members, and interested itself in contemporary letters. Swift often submitted his new publications for criticism at this club, and it is probable that the discussions of the members had a guiding influence on *The Examiner*, the Tory periodical which he edited.

The Whig group which gathered around Addison at Button's coffee house, including Sir Richard Steele, Eustace Budgell, Thomas Tickell and Sir William Davenant, was concerned at its meetings with the correction of verses and the planning of periodical essays. The famous Scriblerus club, which took its name from the name "Martinus Scriblerus" given originally to Swift, had Alexander Pope, John Gay, John Arbuthnot and Thomas Parnell, as well as Swift himself, as its members. As the character of Scriblerus became established, any member wishing to write under a pseudonym could use it, and all works written under this name were directed against false learning. *The Complete Memoirs of Martin Scriblerus* was published in 1741. The main importance of the society, however, was in directing the literary interests of five important writers (Pope, Gay, Arbuthnot, Parnell and Swift) and it seems likely that at least Gay's *Beggar's Opera* and Swift's attack on pseudoscience in the third part of *Gulliver's Travels* were products of its discussions. The Club, later called the Literary club, founded by Dr. Johnson in 1764, was a similar discussion group of eminent literary figures, including Edmund Burke, Oliver Goldsmith, Joseph and Thomas Wharton, Edward Gibbon and James Boswell, which met at the Turk's

Head tavern in Soho once a week.

Several similar mutual encouragement societies arose in the United States at the end of the 18th century. In 1793 Elihu Hubbard Smith became the centre of the Friendly club in New York, of which William Dunlap, Noah Webster and C. B. Brown were members. Others were Joseph Dennie's Tuesday club, Peter Irving's Knickerbocker group, whose superficially sophisticated work was criticized by Edgar Allan Poe in his sketches entitled "The Literati of New York," and the Bread and Cheese club which gathered around Fenimore Cooper. At the so-called Transcendental club which met in Ralph Waldo Emerson's home in Concord, Mass., Bronson Alcott, Henry David Thoreau, Margaret Fuller and others discussed philosophy, theology and literature in open forum.

In 17th- and 18th-century France the equivalent of these clubs is to be found in the literary and social *salons* of Mme de Rambouillet, Mme Scarron and others. In England, at least, the club as a literary group declined as a result of the loss of the intimacy of 18th-century society and the gradual divergence of the worlds of letters and fashion. (See also CLUB.)

Learned Societies.—The 19th century saw the rise of the learned societies which retained their importance into the 20th century by offering centres for discussion, an organized means of preserving literary monuments and literary knowledge, and an opportunity for scholarly publication. The earliest in England was the Assembly of Antiquaries (1572), mentioned above, which was incorporated as the Society of Antiquaries in 1751. In 1812 there was founded the exclusive Roxburghe club for bibliophiles, each member of which in turn presented a new edition of an old text. Its Scottish equivalent, the Bannantyne club, was founded in 1823 with Sir Walter Scott as its president. The Camden society (1838) also laid the foundations for later research by publishing early texts, including the *Peterborough Chronicle*, the works of Walter Map and the *Ancrene Riwle*. Other important organizations of the type were the Shakespeare society (1840), the New Shakespeare society (1874) and the Percy society (1840). Members of the last included Thomas Wright, Alexander Dyce, John Halliwell and John Payne Collier, and the society was responsible for the publication of the works of Stephen Hawes, John Lydgate and Chaucer as well as editions of many ballads, tracts and interludes. The Philological society (1842) devoted most of its energies to the publication of the *New English Dictionary*, later the *Oxford English Dictionary*, and it was while working at this that F. J. Furnivall realized the need for more editions of Middle English texts, which led him to establish the Early English Text society in 1864.

The Royal Society of Literature of the United Kingdom (1825) was the only 19th-century society in England with royal patronage, but it lacked scholars among its first officers, and ill-defined aims led to the dissipation of its energies on diverse subjects: archaeology, geography, religion and economics. Its chief attempt at a work of value to literature, the publication of a *Biographia Britannica Literaria*, begun in 1842, only reached the second volume.

Modern Societies.—*Great Britain.*—Important societies in the first half of the 20th century included the English association (1906), founded to promote knowledge of English language and literature, which publishes the periodicals *English* and *Essays and Studies* as well as the annual review *The Year's Work in English Studies*; the Poetry society (1906), for the study and appreciation of poetry; and the Malone society (1906), for the study of early English drama. Specialist societies devoting their attention to the life and work of one author include the Francis Bacon society (1886), the Brontë society (1893), the Dickens fellowship (1902), the Kipling society (1927), the Johnson society of London (1928), the Shaw society (1941) and the Conrad society (1951).

The United States.—In the United States the earliest philological society, the American Philological society, was founded in 1868 and devoted its activities to American dialects and spelling reform. It was followed in 1883 by the Modern Language Association of America, best known for its distinguished *Publications*, a periodical collection of literary and linguistic monographs known to scholars by its initials *PMLA*. From this association arose the

Concordance society (1906) which fostered the publication of concordances to the works of such authors as Wordsworth and Gray. The most important U.S. societies concerned with the publication of texts include the Grolier club (1884), which publishes valuable books in fine editions; the Dunlap society (1885), for the preservation and publication of U.S. dramatic writing; and the Augustan Reprint society (1946). As well as the Shakespeare Association of America (1923) there are Shakespeare societies in most of the main cities, and there are also numerous societies devoted to individual authors, many of them American, such as the International Mark Twain society (1936) and the Walt Whitman society (1936).

Europe.—Most European countries have writers' unions, the functions of which include the sponsoring and promotion of members' work, the organization of discussions and cultural exchanges with other countries and often legal representation and financial aid. Eastern European countries in particular, including Poland, Czechoslovakia and the U.S.S.R., cultivate this type of society. Soviet literature is served, in addition, by the Gorki Literary institute and by the Gorki Institute of World Literature attached to the U.S.S.R. Academy of Sciences. In the Netherlands the Maatschappij der Nederlandse Letterkunde (1776) promotes national literature, art and history; Portuguese writers are represented by the Sociedade Portuguesa de Escritores and Belgian authors by the Vereniging van Vlaamse Letterkundigen and the Association des Écrivains Belges de Langue Française.

In addition to these national bodies many countries have a branch of the International P.E.N. club for poets, playwrights, editors, essayists and novelists, which aims to promote free cultural exchange between countries and to defend the right of all writers to freedom of expression.

In France the Académie de Franche-Poésie (1919) comprises an *école de poésie*, a library and a *salon* and supervises the *Oeuvre National des Études Poétiques*. Many other French societies are chiefly important as distributors of valuable and distinguished literary prizes. Among them the exclusive Académie Goncourt, the Académie des Lettres et des Arts and the Académie Montaigne are notable, as well as the Maison de Poésie which owns an extensive library.

An important contribution to Shakespeare studies is made in Germany by the Deutsche Shakespeare-Gesellschaft (1864) which publishes the celebrated *Shakespeare Jahrbuch*. Publication of editions of the work of German authors, and of books and articles about them, is undertaken by such societies as the Hölderlin-Gesellschaft (1943), the Goethe-Gesellschaft (1885) and the Gerhart Hauptmann-Archiv (1949). The appreciation of German literature in general is promoted by the Gesellschaft für Deutsche Literatur (1888), and young authors are encouraged by the annual award made by the society known as the "Gruppe 47" for promising new work.

The Società Nazionale Dante Alighieri (1889) aims to spread Italian language and culture throughout the world and founds and subsidizes schools, libraries, courses, prizes and scholarships as well as publishing *Studi Danteschi*. The Casa di Dante, founded in Rome in 1914, concentrates on research into Dante's life and works, publishes a bibliography entitled *L'Alighieri* and issues the *Lectura Dantis Romana* at intervals. General literature is covered by such organizations as the Società Letteraria at Verona and the Istituto Nazionale del Dramma Italiano in Rome.

BIBLIOGRAPHY.—H. R. Steeves, *Learned Societies and English Literary Scholarship* (1913); R. J. Allen, *The Clubs of Augustan London* (1933); see also *The World of Learning* (published annually).

LITHGOW, a city and coal-mining and industrial centre of New South Wales, Austr., situated 3,000 ft. above sea level on the western slopes of the Blue mountains, 92 mi. W. of Sydney by road. Pop. (1961) 14,229. The town lies along the Lithgow valley, overlooked by heavily timbered mountain slopes. The first large-scale slaughtering and chilling works in Australia was built there in 1873, and a successful iron and steelworks, later moved to Port Kembla, was established there in 1875. Lying at the heart of the western coal field, Lithgow is surrounded by mines, including the state coal mine. Its industries include the

Australian commonwealth small-arms factory (the largest engineering works in the southern hemisphere), a brickworks and woolen and textile mills. One of the early railway engineering wonders of the world, the famous Zig Zag (after 1910 superseded by a series of tunnels), is near Lithgow and has been preserved.

(R. J. LR.)

LITHIUM, a chemically reactive metallic element which resembles somewhat the other alkali metals, sodium, potassium, rubidium and caesium with which it is classified in group I of

TABLE I.—Uses of Lithium

Field	Application	Form
Agriculture	Tobacco culture Soil moisture retention Fungicides	Lithium carbonate
Air Conditioning	Moisture absorption Dehumidification	Lithium bromide Lithium chloride
Atomic Energy	Proton production Tritium production Power development	Lithium metal Lithium hydride
Batteries	Atomic hydrogen Primary cells (dry batteries) Storage batteries (alkaline type)	Lithium chloride Lithium hydroxide
Bleaching	Production of solid, soluble, and stable bleaching agents	Lithium hypochlorite Lithium peroxide
Ceramics	Porcelain enamels Ground coats and cover-coats on steel and aluminum for acid resistance, improved bonding, lower firing temperature	Lithium carbonate, manganite, titanate, silicate, zirconate and cobaltite Lithium minerals
Chemicals	Pottery glazes Special glasses Production of miscellaneous lithium compounds	Lithium carbonate
Gas Purification	Catalysts Removal of trace impurities in helium, argon, etc. Carbon dioxide removal	Lithium metal Anhydrous lithium hydroxide Lithium nitrate
Heat Transfer	Stable low melting point Salt mixtures	Lithium metal and alloys
Iron and Steel	Nodular iron grain refinement in steels Desulfurization of steel	Lithium carbonate Magnesium alloys High-purity lithium metal
Nonferrous Metals	Chrome bronzes, high-conductivity copper castings Bronze, nickel, silver, monel and precious metal castings Bearing metals Aluminum castings Lithium metal cartridges	
Petroleum	Catalysts Sulfur removal Lubricants	Lithium metal Lithium hydride Lithium hydroxide Lithium stearate Lithium amide
Pharmaceuticals	Low-temperature greases Reagent to produce antihistamines Reagent to produce synthetic vitamins	
Plastics	Stabilizers Catalysts	Lithium metal Lithium stearate Lithium lactate Lithium carbonate Lithium hydride Lithium nitrate Lithium chloride Lithium fluoride
Rescue and Signal Work	Balloon inflation Flares	
Welding	Fluxes for aluminum and magnesium	

the periodic system. However, as the first member of the group, lithium is unique and has certain properties which render it distinct from its congeners and somewhat similar to magnesium and several other metals of group II. For example, lithium is the only element of its group to react with nitrogen to form a nitride, Li_3N , whereas all of the metals of group II undergo a similar reaction. It is also unusual in that it is the lightest of all solid elements and at ordinary temperatures has a higher specific heat than any other substance except water.

Lithium was discovered in 1817 by J. A. Arfvedson in Sweden who, while analyzing the mineral petalite, found that the sodium compounds which he separated were contaminated by an alkali which did not respond to the chemical tests for the only other known alkali, potassium. The name lithium (from the Greek, *lithos*, "stone") was proposed by J. J. Berzelius. It was first isolated in quantity in 1855 by R. Bunsen and A. Matthiessen who electrolyzed fused lithium chloride.

Uses.—Lithium was generally unknown and had few uses for more than a century after its discovery. The United States, the world's largest producer, averaged 290,000 lb. of lithium carbonate (or its equivalent) per year for 1935–39. During World War II a peak of 2,790,000 lb. was reached (1944); this was exceeded in

every year after 1950, reaching more than 30,000,000 lb. per year in the 1960s. The metal has been used as a constituent of certain light metal alloys, with magnesium and aluminum-zinc alloys and in heavy-duty lead bearing alloys. It is used as a de-gasifier in the production of high-conductivity copper and bronze castings and is also used in the synthesis of vitamin A. Lithium compounds are used in lubricants and ceramics, which consume the largest quantities, and in air conditioning, welding and brazing. Nuclear applications include H-bombs, nuclear power and high-energy fuels.

Occurrence and Production.—It is estimated that lithium constitutes about 0.0065% of the igneous rocks of the earth. Because of its high chemical activity, the element occurs only in combination and its compounds are widely distributed but in small concentrations. Traces of lithium are found in animal tissue, plants (especially tobacco), the soil and a large number of minerals. Small quantities occur in sea water and in some springs. The few minerals which contain lithium in quantities sufficient for commercial extraction are: spodumene $\text{LiAl}(\text{SiO}_3)_2$, petalite $\text{LiAl}(\text{SiO}_2)_2(\text{SiO}_3)_2$, lepidolite $(\text{Li}, \text{K}, \text{Na})_2\text{Al}_2(\text{F}, \text{OH})_2(\text{SiO}_3)_3$, amblygonite $\text{LiAl}(\text{F}, \text{OH})\text{PO}_4$ and triphylite $\text{Li}(\text{Fe}, \text{Mn})\text{PO}_4$.

Producing countries of lithium minerals include the United States and Canada, Australia, Argentina and Brazil and a number of countries in Africa (Southern Rhodesia in central Africa, South West Africa, Uganda, Republic of South Africa, Republic of the [former Belgian] Congo and Mozambique [Portuguese East Africa]).

Lithium compounds are separated from the minerals by various methods. Generally, in the case of spodumene, the ore is heated to approximately $1,100^\circ \text{C}$. to decrepitate the mineral from the γ , or hard form, to the β , or soft form (see *SPODUMENE*). The decrepitated material is ground, mixed with strong H_2SO_4 , and heated to 150° – 250°C . to render the lithium soluble as a sulfate.

In the second case (petalite) limestone is mixed with the ore or concentrates and heated to approximately $1,100^\circ \text{C}$. The decrepitated material thus formed with the calcined lime is ground and leached to produce a solution of lithium hydroxide.

Phosphate ores (amblygonite) are treated with strong sulfuric acid recovering the lithium as sulfate and recovering also the phosphorus as a sodium or calcium acid phosphate. The lithium and other soluble sulfates are extracted with water and from the purified solution the crude lithium carbonate is precipitated.

The crude carbonate is converted to the dry anhydrous chloride or bromide which is separated from the impurities by use of an organic solvent, e.g., amyl alcohol, a mixture of ethyl alcohol and diethyl ether, or pyridine.

Lithium metal is obtained by the electrolysis of a fused lithium chloride and potassium chloride salt mixture containing 40%–50% of lithium chloride. Other methods of reduction have been tried but fused salt electrolysis is the process used commercially.

Properties.—Lithium is a white metal with a silvery lustre which quickly tarnishes when exposed to moist air. Its symbol is Li, atomic number 3, chemical atomic weight 6.939. Two naturally occurring stable isotopes with mass numbers 6 (7.5%) and 7 (92.5%) are known; radioactive isotopes, 8 (half life 0.83 sec.) and 9 (0.17 sec.) have been prepared. It has a hardness of 0.6 on Mohs' scale and is harder than the other alkali metals but softer than lead which it resembles in ductility. The crystal lattice of the metal is of the body-centred cubic structure with the distance of closest approach of the nuclei equal to 3.03 Å (angstrom unit = 10^{-8} cm). Its spectrum like those of the other alkali metals is comparatively simple and is characterized by a bright-red line (6708 Å) and a fainter orange line (6104 Å).

For additional physical and atomic properties see Table II.

Lithium is an active metal and a strong reducing agent, readily giving up its 2s electron to form lithium ion, Li^+ . It reacts with water at ordinary temperatures liberating hydrogen and forming a solution of lithium hydroxide, a strong base or alkali. Lithium burns in air forming the oxide, Li_2O ; at red heat it unites with hydrogen forming the hydride, LiH ; it reacts with the halogens and at higher temperatures with phosphorus, arsenic, antimony, carbon, silicon, sulfur and selenium. It is not as reactive as the

other alkali metals but in common with them dissolves in liquid ammonia to give a highly conducting coloured solution. It is thought that the colour is caused by single electrons and electron pairs which are trapped in cavities of the liquid rather than by solvated electrons. The normally stable nuclei of lithium undergo transformations when bombarded with rapidly moving particles: with protons, $\text{Li}^6 + \text{H}^1 \rightarrow \text{He}^4 + \text{He}^3$, $\text{Li}^7 + \text{H}^1 \rightarrow 2\text{He}^4$; with deuterons, $\text{Li}^7 + \text{H}^2 \rightarrow \text{Li}^8 + \text{H}^1$; with neutrons, $\text{Li}^6 + \text{N}^1 \rightarrow \text{He}^4 + \text{H}^3$. In the last reaction, used to prepare tritium, the lithium is bombarded with slow moving neutrons which are produced in a uranium pile (see *DEUTERIUM AND TRITIUM*).

Compounds.—The compounds of lithium are predominantly ionic and their chemical properties are in part those of the lithium ion. This ion, the smallest of the alkali group, attracts an electron more strongly than the others and is more easily reduced to the metal. It also attracts water molecules most strongly with the liberation of a large amount of energy, thereby facilitating the reaction of lithium metal with water. As a result, lithium has a high electrode potential in water solution, greater than that of cesium, instead of the lowest of the group which might be expected from the ionization potential.

Lithium hydride is a white solid with a crystalline structure of the sodium chloride type and a melting point of 688°C . Electrolysis of the fused compound liberates lithium at the cathode and hydrogen at the anode. It is typical of the class of "saltlike" hydrides which are formed by the elements of groups I and II. Lithium aluminum hydride, LiAlH_4 , and lithium borohydride, LiBH_4 , in common with lithium hydride are strong reducing agents and react with water to liberate hydrogen and form the metal hydroxides. Lithium aluminum hydride is extensively used as a reducing agent in organic syntheses.

Lithium carbonate, Li_2CO_3 , a sparingly soluble salt, is used in the preparation of a number of other lithium compounds, in ceramics for producing glazes and in manufacturing special grades of glass. The bicarbonate, LiHCO_3 , is soluble in water. Lithium fluoride, LiF , has the highest heat of formation of all of the alkali halides and is one of the most stable compounds known. It is somewhat insoluble and is used in soldering and welding fluxes. The bromide, LiBr , used as a drying agent in air conditioners and the iodide, LiI , used in photography are both soluble. The nitrate, LiNO_3 , the sulfate, Li_2SO_4 , the sulfide, Li_2S , and the perchlorate, LiClO_4 , are all soluble while the normal phosphate, Li_3PO_4 , and the oxalate, $\text{Li}_2\text{C}_2\text{O}_4$, are insoluble.

Organolithium compounds; e.g., butyllithium, $\text{C}_4\text{H}_9\text{Li}$, and phenyllithium, $\text{C}_6\text{H}_5\text{Li}$, used for introducing alkyl or aryl groups into organic molecules, are prepared by the reaction of lithium with the appropriate organic halides. The reaction of these organolithium compounds with a variety of other substances is a common preparative procedure, resembling somewhat the methods involving the Grignard reagents (organomagnesium compounds). Organic salts of lithium, the benzoate, citrate, salicylate and the acid tartrate as well as inorganic salts were formerly employed in medicine, some for the elimination of uric acid in the treatment of gout and rheumatic conditions. However, the tolerated dose of lithium cannot form the relatively soluble lithium urate in the presence of the quantities of sodium and potassium normally in the blood serum and accordingly lithium salts have been largely superseded in medicine by other diuretics.

Determination.—Lithium may be identified by the use of a spectroscope or by the red colour it imparts to a flame. It is gravimetrically determined in the presence of the other members

of the group by extraction of the chloride with amyl alcohol. Another procedure involves the use of the flame photometer; a lithium salt solution is fed to a flame, the light passes through a prism and one of the characteristic lines impinges upon a photoelectric cell. See also references under "Lithium" in the Index.

LITHOCARPUS is a genus of about 100 species of evergreen oaklike trees of the beech family (Fagaceae), all native to Asia except one species that is abundant along the coast of Oregon and California. This native species, *L. densiflora* (formerly *Quercus densiflora*), commonly known as tanbark oak or tan oak, is important for its bark, which is used in tanning leather, and for its ornamental value. See **TANBARK OAK**. (J. M. BL.)

LITHOGRAPH, a planographic print made by a process that relies on the natural antipathy of grease to water. This article considers the lithograph in art; for the commercial printing process see **LITHOGRAPHY**. Lithographs as an art form are printed on specially constructed presses from a drawing, usually on stone (hence the name, from the Greek *lithos*, "stone," and *graphein*, "to write"), but metal plates can also be used. These processes are described in the section on technique, which follows the section on history.

HISTORY

ORIGIN

Lithography is one of the very few graphic mediums that has a recorded origin; it was invented in 1798 by a Bavarian, Aloys Senefelder, who documented his discovery and subsequent experiments in *Vollständiges Lehrbuch der Steindruckerey* (1818; Eng. trans., *A Complete Course of Lithography*). The term *Steindruck* ("stone printing," i.e., lithography) was not Senefelder's original name for the process. Actually the use of stones was incidental to his experiments, which were concerned with what he termed chemical printing; his objective was a cheap form of commercial printing that would enable him to publish his own dramatic productions. According to Senefelder, the use of stone as a printing surface came to him in 1796, when, by force of circumstance, he jotted down a laundry list for his mother with a greasy pencil on a piece of stone. It occurred to him that the markings on the stone could be left in relief if the rest of the surface were etched away. His earliest experiments were from these etched stones, as well as metal plates, printed in relief. Further experimentation led, in two years, to the type of flat-surface printing that is called lithography. By the time his book appeared in 1818, Senefelder had experimented with and described every process in modern lithography.

Senefelder's interest in lithography was a purely commercial one. To this end he accepted an offer from the music publisher Johann Anton André to establish himself at Offenbach and to train persons in the new process. As a result of this kind of partnership, and at André's suggestion, patents were secured in various localities, including London.

19TH CENTURY

Germany.—In Bavaria, under the impetus of Senefelder's press at Munich, commercial lithography proceeded to develop as a reproductive medium; the first important publication was a facsimile edition of Albrecht Dürer's *Missal of Maximilian* in 1808, redrawn on stone by Johann Nepomuk Strixner. Other reproductive lithographs were produced in great quantities by the Quaglios, Karl von Piloty and others.

An abortive attempt to produce an original lithograph was made by the Bavarian count Törring-Seefeld in 1800. His views of the Lake of Wörth, as well as similar attempts by Mitterer and his pupil Angelo Quaglio, failed. E. J. Aurnhammer, a professor at the Gymnasium of Regensburg, sent 12 landscape subjects on stone to Senefelder in 1802 for printing in Munich, but only 6 survived. In the publication *Polyautographische Zeich-*

nungen vorzüglicher Berliner Künstler of 1804 appeared a lithograph by Johann Gottfried Schadow, who can be credited with being the first German artist of merit to take up lithography. Schadow produced 45 lithographs in all. Another contributor to this publication, as well as its publisher, was the painter Wilhelm Reuter, who had interested himself in the process since 1801. The architect Karl Friedrich Schinkel also made a few lithographs; one of a Gothic church done in 1810 is an exceptionally fine pen lithograph. For the greater part of the 19th century, lithography was not very highly regarded by the most competent artists. However, mention should be made of Joseph Kriehuber, the favourite portraitist of the Vienna school, who drew many of his heads on stone. Adolf von Menzel, also well known as a book illustrator in wood engraving, kept the art alive with competent technical knowledge and accomplished drawing, displaying a special virtuosity with the white scratched-line technique. Toward the end of the century, Hans Thoma took up the medium, experimenting with colour prints and encouraging other artists; and Otto Greiner worked many of his figure studies on stone.

France.—The first attempt at lithography in France was unsuccessfully conducted by Frédéric André, while the earliest effective French trials by Pierre Nolasque Bergeret were published not in France but by an English art dealer, Bell, in 1801. The first lithograph drawn and produced in France is considered to be "Le Mercure" by Bergeret, done in 1804. However, lithography did not receive official recognition until 1809, when the director-general of museums, Vivant Denon, drew a Holy Family at Senefelder's shop in Munich.

Lithography developed in France as in no other country. Gradually taking hold of the imagination of both amateur and professional artists, the new medium appealed as an autographic way to reproduce drawings. Most of the work of the early French lithographers, Carle Vernet, N. T. Charlet, who produced around 1,000 prints, Eugène Lami and Denon, was drawn in simple black lines with a minimum of shading. The painter Eugène Delacroix took up lithography and became a master of the technique; his professional stature added prestige to the new process, by which he produced nearly 100 prints, including illustrations to *Faust*, *Hamlet* and other dramas. Other outstanding artists of this early period were Eugène Isabey and the immensely influential Théodore Géricault, who lithographed many studies of horses. Pierre Paul Prud'hon, Théodore Chassériau and Auguste Raffet were other significant contributors to the art.

From 1820 to 1863 there appeared a monument to lithographic illustration in the form of Baron L. J. S. Taylor's *Voyages pittoresques et romantiques dans l'ancienne France*, with contributions by Isabey, Géricault, Célestin Nanteuil and many others.

The most prolific figure in 19th-century French lithography was undoubtedly Honoré Daumier, who, between 1830 and his death, in 1879, made nearly 4,000 caricatures. These appeared in the political journals and newspapers of his era and earned him an unshakable place in the great tradition of art and humour. Paul Gavarni followed closely as a chronicler of fashionable Paris.

A decline set in everywhere around mid-century, due not only to excessive commercialization of lithography but also to the newly developed technique of photography and its application to the various reproductive processes. A revival from this setback came about in the decade of the 1870s. Camille Corot began working in the medium in 1871; his work includes 18 pieces. Edgar Degas tried lithography for the first time in 1874; a tireless innovator, he saw in it yet another outlet for his versatile talents. Édouard Manet, whose first work on stone was done in 1862, illustrated Poe's "The Raven" in 1875; Camille Pissarro made his first 12 lithographs in 1874. Rodolphe Bresdin created some lithographs, even transferring some of his etchings to stone. His pupil Odilon Redon practically abandoned painting for lithography from 1883 to 1899, creating eerie and mystical subjects.

Colour lithography, already used by Manet for his plate "Polichinelle" in 1876 and by Jules Chéret, a pioneer of the colour poster, reached its zenith in the 1890s. Henri de Toulouse-Lautrec, a technical innovator, a magnificent poster artist and a

great portrayer of the theatre and the arts of the 19th century, executed his "Moulin Rouge"—his first colour poster—in 1891. To the Impressionists also, colour was all important; Édouard Vuillard was producing such colour masterpieces as his *Douze Lithographies en couleurs* during this decade; and Pierre Bonnard, his *Quelques Aspects de la vie de Paris*. Other powerful artists who turned their hands to lithography in the last quarter of the century were Paul Gauguin, Eugène Carrière, Pierre Puvis de Chavannes and Ignace Fantin-Latour.

England.—Lithography in England received its initial impetus from Senefelder himself and his business associates. In 1800 they went to London to obtain a patent and to arouse interest in the new process. The patent was obtained in 1801; the promotional effort took the form of a publication entitled *Specimens of Polyautography*: . . . appearing in 1803. Several well-known artists contributed to this first example of lithographic production in England: Benjamin West, Henry Fuseli and Thomas Stothard among others. West's design of the angel at the tomb of Christ is dated 1801 and may be considered the first lithograph of true merit to have been produced.

Despite this promising start, the English did not seem to take to the new medium very readily. Charles Hullmandel issued a series of *Twenty-four Views of Italy* in 1818 and later, in 1821, brought out 12 designs of *Various Subjects Drawn From Life on Stone* by Géricault, who was in London at the time. James Ward did a series of 14 *Celebrated Horses* in 1823, and Richard Parkes Bonington executed some very accomplished colour lithographs, particularly for Baron Taylor's book. Other English artists, such as Samuel Prout, James Duffield Harding and Thomas Shotter Boys, helped continue the tradition; but the process fell into the general pattern of decline until revived in the latter decades of the century by the American expatriate James Abbott McNeill Whistler. Although his work seems slight—particularly his delicate nudes—his influence was strongly felt, perhaps because his colourful career gave an added interest to anything with which he concerned himself.

Elsewhere in Europe.—Lithography had but one important adherent elsewhere on the continent—the great Spanish painter and etcher Francisco Goya, who drew, in all, 23 lithographs. Among them are four bullfight scenes that are a landmark of technical virtuosity and compositional strength.

United States.—The first lithograph produced by an American was the one mentioned above by West in 1801, for he was actually an American working in England. So far as lithography on the American continent is concerned, however, the introduction of the process to the United States is credited to Bass Otis of Philadelphia, Pa. In 1818 Otis etched on stone a portrait of Abner Kneeland for a frontispiece to a book of sermons by that clergyman. However, a little view of a mill, appearing in the July 1819 issue of the *Analectic Magazine*, is regarded as the first true American lithograph. Rembrandt Peale was among the first artists to employ the medium. Other important early figures were Thomas Doughty; George Lehman, who lithographed scenes in Pennsylvania; J. C. Wild, who executed an important set of Philadelphia views; August Kollner; Christian Schussele, an influential art instructor; Albert Newsam, a deaf-mute artist and lithographer of hundreds of portraits; and M. E. D. Brown.

When reviewing lithography of the 19th century in the U.S., there must be taken into account the tremendous output of the publishers Nathaniel Currier and James Merritt Ives, who produced well over 6,000 lithographs after the designs of such well-known artists as George Inness, A. F. Tait, Louis Maurer, F. F. Palmer, Eastman Johnson and many others (see CURRIER & IVES). The publishing houses of Sarony and Major, and the Kelloggs, were also prolific. Not to be forgotten is Winslow Homer, who made a strong contribution with his *Campaign Sketches* of the American Civil War.

20TH CENTURY

The painter-lithographer tradition again declined during the early part of the 20th century. French artists, such as Degas, Paul Signac, Auguste Renoir, Bonnard, Jean Louis Forain, Vuil-

lard, Maurice Denis, T. A. Steinlen and Mary Cassatt, as yet unrecognized in her native America, seemed to be working in isolation so far as their work influenced the medium elsewhere. In England the Senefelder club was formed in 1909 to provide an outlet for artists working in lithography. Augustus John, John Copley, Ethel Gabain, Charles H. Shannon and William Rothenstein were a few who kept the art lively. In Germany the Expressionist school was coming to the fore. Though its work was not immediately understood or appreciated, it gradually received recognition as one of the most powerful molders of 20th-century art. Käthe Kollwitz, the Norwegian Edvard Munch, Lovis Corinth, Max Slevogt, Max Liebermann, E. L. Kirchner, Emil Nolde, Max Beckmann, Ernst Barlach, Oskar Kokoschka, Paul Klee, the American Lyonel Feininger and George Grosz were among the group that challenged the ideal of beauty by rugged emotional display.

In the United States Joseph Pennell, whose work both in the U.S. and England, as well as his book on lithography (1st ed., 1898), made him an important proponent of the medium, led a strong group followed by George Bellows, "Pop" Hart, Bolton Brown, Albert Sterner, Arthur B. Davies, Childe Hassam, Rockwell Kent and Mabel Dwight, as well as Max Kahn, Stow Wengert, Benton Spruance, Adolf Dehn, Francis Chapin, George Biddle, William Gropper and Robert Riggs.

During this century an exciting group of lithographs came from the leading painters of Mexico: José Clemente Orozco, Diego Rivera, David Alfaro Siqueiros, Jean Charlot and Rufino Tamayo. In England, where lithography never was very popular, the names of Graham Sutherland, Henry Moore and Robert Colquhoun stand out.

It was from the school of Paris, however, that a vigorous revival of lithography came. To those giants of painting, Henri Matisse, Marc Chagall, Georges Rouault, Fernand Léger, Georges Braque and, above all, Pablo Picasso, with his prodigious output, is owed the tremendous popularity of the medium. Their influence has been international not only in stimulating all the graphic arts but also in freeing them from superficial limitations of size, technique and other preciousness. The colour lithograph, along with other colour-print processes, now rivaled paintings in size and attractiveness.

Printers and Publishers.—It should be remembered that most of the work of the school of Paris came about through the availability of dedicated lithographic printers. In Paris the firms of Fernand Mourlot and "Papa" Desjobert, with their enthusiasm and encouragement, made possible much of mid-20th-century lithography. Their accomplishment, however, is a timeless one, for it has ever been true that the greatest flowerings of lithography have come about as a result of the dedication of a few printers serving many artists—stimulating and easing the way for the production of great lithographs. Senefelder himself spent his life spreading information on the technique that he invented and stimulating production through his ability to print. The names of Bolton Brown, Lawrence Barrett and Lynton Kistler are to be remembered in the U.S.; Thomas R. Way, Whistler's printer in England, and before him, Hullmandel will not be forgotten. In France the names of Clot, Rose Joseph Lemerrier, Godefroy Engelmann, Charles Motte, Delpech and Charles Philibert de Lasteyrie du Saillant will be recalled, as well as those of the publishers Ambroise Vollard and David Kanweiler. In Germany Paul Cassirer and the Marées society were important as publishers. (K. McN.)

TECHNIQUE

Lithographs are made as follows: (1) The stone is grained. (2) The outline of the picture to be reproduced is drawn on the stone. (3) The drawing is done with tusche or crayon containing grease. (4) The stone is etched, placed in position on the press bedplate and washed with turpentine, which removes the soap and wax from the tusche or crayon. (5) The stone is dampened and rolled (inked). The drawing on the stone repels the water. The thin film of water on the bare parts, in addition to repelling ink, actually prevents the inked roller from touching those areas of the

stone. Therefore, only those parts of the stone that have been drawn on with the grease material receive the ink, and all bare parts of the stone that have been moistened with water do not take the ink and do not print. It is then covered first with a piece of dampened printing paper, then with backing, which consists of two or three clean blotters, next with the tympan (a piece of hard fibreboard) and printed. The stone is dampened and rolled for each successive print. Hundreds, or thousands if necessary, of prints can be made from a stone or zinc plate. Lithographs can be made in multiple colours by printing with coloured inks, using a separate stone for each colour.

The Stone.—The best lithographic stones come from Solnhofen and Kelheim in Bavaria. Of a form of limestone found deep in the earth, they are of even thickness and perfectly flat. Stones are classified according to colour: blue (hard), blue-gray (medium) and yellow (soft). Blue-gray stones are preferred by artists. Both stones and metal plates must be grained with an abrasive to prepare them for the drawing. Stones are grained by rubbing together in a circular motion two stones with wet carborundum grit between them. Their positions are occasionally reversed, and more grit and water are added until any former design has completely disappeared. The size of the grit determines the texture of the drawing surface. Care must be taken to protect the stone from grease, dandruff, saliva or fly specks. A piece of cloth, tissue or a barrel stave is used as a bridge to prevent the hand from touching the stone while the artist is working on it.

The Drawing.—A nongrease crayon is used to sketch the outline of the drawing on the stone. The drawing should be reversed, since a print comes off the stone as a mirror image of the drawing.

Several drawing techniques are used in making lithographs. Lithographic crayons are supplied in both stick and pencil form in a wide range of grades from no. 0 (very soft) to very hard Copal no. 5. Tusche is supplied in bottles and in stick form. The liquid kind, often called ink, makes solid black areas when applied with a brush, and thin, sensitive lines when applied with a pen. Stick tusche, which must be dissolved in water, is used for wash lithographs called lithotints and for dry-brush lithographs. Smutty, close-grained dark grays are made by rubbing dark areas with a piece of felt or by scraping and shaving with a razor blade. Razor blades are used to soften hard, dark edges and sometimes are used to lighten or scrape out parts and make interesting textures. When a lithograph is to have a solid, dark-gray undertone for the background, such a tone can be laid on the clean, blank stone with a lightly inked composition roller. Parts of the tone can be scraped away or washed out with gasoline to make light areas, and dark areas can be added with tusche and crayon.

Areas can be lightened and textured by laying a piece of tissue paper on the stone and crosshatching over it with a lead pencil or stylus. When the tissue paper is peeled off some of the crayon will adhere to the underside of the paper. Crisp white lines are scratched into dark areas with sharp-pointed tools: razor blade, needle, penknife, etc. The result often resembles a wood engraving. Sharp tools are useful for making dark tones lighter by picking out some of the dots that make up the tone. Small areas can be erased by placing a pinch of carborundum grit or flint on the spot and regrinding with the flat bottom surface of a glass bottle stopper. Striking textural effects are obtained by use of an ink eraser.

To make a lithographic engraving, a fairly soft stone is grained with extra fine carborundum grit or flint. The stone is lightly etched, smoothed with cloth and dried. The drawing is made with a lithographer's engraving needle, which has five facets. Wide shallow lines are made by pulling the needle—not pushing it—to scratch through the gum, barely into the stone. Errors are corrected by applying a thin gum covering, which then can be engraved again. When the engraved drawing is finished, first light machine oil, then lithographic ink, is rubbed in. The printing is done in the usual way, described below.

Lithographic printing is a difficult and complicated operation and is usually done by a professional printer rather than by the artist.

The Etch.—Before printing, lithographs must be etched, to set the drawing to the stone, and cleaned of excess grease that has spread out from the drawings. The etching solution for stones is prepared by pouring a few ounces of gum solution, i.e., about equal parts by volume of water and gum acacia, into a small bowl and adding half a teaspoonful of nitric acid. The gum solution desensitizes the surface not drawn on, decreasing its affinity for grease; the acid eats away any invisible particles of grease that may be on the surface but, when in the correct solution, does not affect the drawing itself, which is protected by the wax in the lithographic crayon. Etching solution is applied to the stone with a large soft brush.

The amount of acid required for the etch solution depends upon many factors, such as room temperature, hardness of the stone, type and age of the drawing and strength of the acid. Often, some parts of the drawing that require a stronger etch than other parts must be gone over with a brush and a stronger solution.

Printing.—Having properly etched the stone, the printer removes the excess gum with a rubber plate scraper and fans it dry. Then he gently rubs it with a damp cloth and a few drops of gum solution. After it has dried, the printer washes off the crayon drawing with turpentine and a soft cloth, leaving the drawing invisible, apparently destroyed; but it is preserved, of course, in the grease still remaining in the pores of the stone. He then rubs ink or asphaltum into the stone. As soon as this has dried, the stone is sponged with water and rolled with a grained roller well charged with lithographic ink. Lithographic ink comes out of pound cans in tarlike chunks; it must be kneaded and thinned with lithographic varnish before using. A small amount is spread onto a slab of stone, and the roller is charged with ink by rolling it briskly over this slab until it produces an audible hissing sound.

A lithograph is printed on a specially constructed press, which has a traveling bedplate that carries the freshly inked stone with dampened paper, backing and tympan under a leather-covered scraper. When the crank is turned, the inked image is rubbed or scraped off the stone onto the paper as it is forced through the press. The scraper is kept well greased to reduce friction. Lithographic presses weigh several hundred pounds.

The first few prints "pulled" (printed) are light, because the stone has absorbed some of the first ink applied. Printing can be interrupted at any time to make corrections. Small areas can be scratched out or lightened with a razor blade and the areas lightly swabbed with a 2% solution of phosphoric acid. When additional work is to be added, the stone must first be counteretched. This is done by inking the stone, dusting it with rosin to dry the ink and washing it with a saturated solution of alum (called counter-etch solution). The new work is added and the stone etched again. Then the whole process of preparation and printing is repeated.

If the prints keep getting darker as the edition progresses, the stone must be re-etched. To do this the printer inks it, dusts it, etches it again, washes it out and prints it as before. If the stone is to be put away for future printing, it should be rolled, dusted, etched very lightly and covered with thin paper while wet.

Transferring.—Many print makers prefer to draw lithographs on paper and have a printer transfer the drawing to stone or zinc for printing. Such transfers often require some additional work to be done on the plate or stone, either by the artist or printer before printing. Transfer lithographs are easily identified because their texture is like the paper they were drawn on. Special transfer papers are available, but any thin paper will do. When an artist draws on paper for transfer he does not have to reverse the drawing. The drawing medium must contain grease.

The drawing must be softened by soaking it for a few minutes in a tray filled with a solution of about 30 drops of nitric acid for each quart of water. The stone or plate used for the transfer must be larger than the print, smoothly grained and warmed slightly. The lithographic press is used to transfer a drawing to the stone. In transferring the drawing while still moist, it is placed face down on the stone or plate and covered with aluminum foil, backing and tympan. The press is adjusted and set for extra pressure to make transfers.

some scratching and scraping
Bottom right: Book illustration by J. L. Géricault (1791-1824), French. An early lithograph done on stone

The drawing, when transferred to stone or plate, will appear weak, but some of the grease will have penetrated the stone, and the design will come up stronger when it is printed. Transfer lithographs should be lightly etched before printing; otherwise they are printed in the same manner as originals. Sometimes transfer lithographs darken during the printing and must be etched again.

Metal Plates.—Lithographs can be made in the same manner on zinc or aluminum plates, which are bought already grained. Metal plates are preferred by some artists because of their convenience in handling. They are very sensitive to grease and are especially suitable for transfers and for lithotints. The technique for drawing on zinc is the same as for drawing on stone. Textural effects are limited. The metal is hard and cannot be scraped or scratched for corrections.

The process for preparing plates varies slightly from that used for stones. After a zinc or aluminum plate has been drawn upon, it is regummed and dried. Then it is etched, washed out with turpentine and water, rubbed up with asphaltum, washed with water, rolled with ink and printed without being allowed to dry again until the edition has been printed.

The etch solution for zinc plates is about 4 oz. of gum solution and 1 tsp. of chloric acid and 12 drops of phosphoric acid; for an aluminum plate, 4 oz. of gum arabic and 15 or 20 drops of phosphoric acid. Commercial preparations are sold for etching zinc and metal plates.

See ETCHING; see also references under "Lithograph" in the Index; and articles on most of the artists mentioned in this article.

LITHOGRAPHY is one of the most widely used methods of printing. In its usual commercial or industrial application it is known as offset lithography because the inked image is first printed on a rubber cylinder, which then offsets or transfers the image to paper or other material. The process is also known as photolithography, photo-offset, offset and planography. Because of the flexibility of the rubber cylinder, lithography can be used to print on tin, wood, cloth, leather and rough, as well as smooth, paper. For a discussion of lithography as an art form, see LITHOGRAPH.

In lithography the matter to be printed is neither raised above (as in letterpress) nor sunk below (as in intaglio) the surface of the plate but remains on the surface, or plane. For this reason the process is sometimes called planography. Lithography is based upon the principle that grease and water do not mix: ink is deposited on grease-treated printing areas, while the nonprinting parts, which hold water, reject the greasy ink.

Lithography is used mainly to produce printed matter that is required in large quantities; e.g., calendars, greeting cards, bank checks and deposit slips, booklets, letterheads, books, magazines, newspapers, maps, posters, billboards, stamps, labels on tin cans, packaging and other advertising matter. Posters can be lithographed on rotary presses either by offset or by direct printing from the plate. Since most posters require strong colour, direct presses are usually used.

Offset lithography is particularly advantageous in long runs (over 10,000) of large-sized sheets. Only gravure can compete with it in certain types of work. Letterpress plates cannot be made so large as offset plates, while silk-screen and collotype methods are suited, for other reasons, mainly for short press runs. (See PRINTING PRESS.)

History.—The lithographic process was invented by Alois Senefelder (q.v.) of Munich, Ger., in 1798. Senefelder had experimented for several years in an effort to discover a cheap method of printing plays and sheet music. In making the first lithographs he used a variety of calcium carbonate stone (limestone) that is found mainly in Bavaria; it has a porous texture that absorbs grease and water. He also suggested the use of grained metal plates, i.e., plates treated so as to give them a granulated surface, but they did not come into general use until the 20th century, when they gradually replaced Bavarian limestone.

However, stone is still preferred by artists for making hand-printed lithographs.

Up to 1818, when Senefelder published a technical description of lithography, the process was used sparingly because the procedural techniques were kept secret. Artists in England, France and Germany published work from 1803 on, but the first lithograph in the United States, drawn by Bass Otis, was not published until 1819 (in the *Analectic Magazine*). After 1825 lithography advanced rapidly.

Many firms were established for producing a variety of commercial work and for distributing popular topical, historical and religious subjects to a wide audience. The best known of these publishers was Currier & Ives (q.v.) of New York. The firm was founded in 1857, although Nathaniel Currier published work from 1834 on. The lithographs were printed in black ink and were often hand-coloured by an assembly line of women, each of whom applied a separate tint of water colour.

Some good early work was done in colour lithography (using printed colours) by Godefroy Engelmann in 1837 and Thomas S. Boys in 1839, but the method did not come into wide commercial use until 1860. It then became the most popular method of colour reproduction for the remainder of the 19th century. These products were called chromolithographs, or chromos, and oleographs. They were made by preparing a separate stone by hand methods for each colour (tint) to be used and printing one colour in register over another. Sometimes as many as 30 stones were employed for a single subject.

The steam-driven lithographic press was perfected by Hughes & Kimber of England about 1865 and introduced into the United States in 1866. These presses utilized automatic rollers to moisten and ink the stone, while the paper was pressed into contact by a revolving cylinder. P. S. Duval, writing in the *American Encyclopaedia of Printing* (1871), said that about 450 hand presses and 30 steam presses were in operation in the country at that time. The power press made it possible to print larger stones than ever before, with sizes up to about 44 by 64 in. Although the offset method of printing was first patented by John Strather of England in 1853, the first practical application of this principle came in the 1870s, when rubber offset rollers were used on flat-bed presses for printing on tin and other metals.

The rotary press for lithographic printing came into use in the late 1890s. Lightweight zinc sheets, which could substitute for the heavy stones, were curved around cylinders for rotary printing. Two main cylinders were used, one for carrying the plate and the other for carrying the paper. Early rotary presses could print about 1,100 impressions per hour, about double the performance of the flat-bed power press then in use.

As soon as photography became a practical process in 1839 because of work by Louis J. M. J. Nicéphore Niépce of France and William Henry Fox Talbot of England, efforts were made to adapt it to lithography. Among early experimenters who reproduced line drawings were Joseph Dixon of the United States in 1840 (his technical description, however, was not published until 1854) and Frédéric Zurcher of France in 1842.

Late in 1852 Rose Joseph Lemerrier, a Parisian lithographer, together with Charles Barreswil, Nicolas P. Lerebours and Louis Alphonse Davanne, made the first photolithographic half tones (prints in a gradation of tones). They used bitumen of Judea (asphalt) for sensitizing the surface of a grained lithograph stone and developed the image, made through a paper negative, with ether. This slow, expensive and dangerous method was superseded by the albumin process patented by Alphonse Poitevin in 1855; this process, which was essentially the same as the albumin process still used in the early 1960s, employed dichromated solutions of albumin, gum or gelatin as light-sensitive coatings.

In 1857 Eduard I. Asser in Holland invented the phototransfer process, which he patented in England in 1860. In this process a photographic image on sensitized paper is inked and transferred to the printing surface. Henry James of England, in 1859, first used grained zinc to replace stones in making phototransfers. J. W. Osborne of Australia improved the transfer process in 1859 and made it commercially feasible for reproducing engravings, pen

and ink drawings, maps and other line work.

James A. Cutting and Lodowick H. Bradford made the first lithographic half tones in the United States, in 1858. The first use of the half-tone screen in lithography was made by Edward and James Bullock of England in 1866. They employed a glass surface or a translucent paper sprinkled with opaque dots. These produced half-tone prints with a granular texture.

William A. Leggo of Canada made half tones in 1869 through a glass screen coated with darkened collodion and ruled with crossing lines drawn with a diamond point. The resulting prints had a dot structure similar to that made from a modern half-tone screen. (This is composed of two sheets of glass, each covered with fine lines running in a diagonal direction; the sheets of glass are fastened together so that the lines form right angles. The resulting crosslined squares break up a reflected image into dots of varying sizes, depending upon the amount of light that penetrates the transparent squares.)

Offset methods for printing on paper were developed separately in the United States shortly after 1900 by Ira W. Rubel of New Jersey, Alex Sherwood of Illinois and A. W. and Charles Harris of Ohio. Rubel, in collaboration with Sherwood, made the first good press in 1906; this later became the Potter press. The Harris brothers, about one month after the Rubel press appeared on the market, made the first press to be commercially exploited. Many of the initial steps in improving offset lithography were taken by William C. Huebner of the United States, who developed the precision all-metal camera, step-and-repeat machines (widely used to produce multiple images on an offset plate) and plate-coating machines.

The use of colour half tones, which was limited before 1920, expanded rapidly after that date because of the introduction of improved methods of dot etching and improved techniques of registration (superimposing one colour over another). The new etching method permitted better tone control by making it possible to reduce the size of the dots when desired.

Offset presses vary greatly in size. The largest can accommodate sheets as large as 52 by 76 in. and can print up to six colours in a single run. Paper can be fed from a roll (web printing) and cut to the desired size in the press after printing. Usually, however, single sheets are fed in. Some offset presses can print on both sides of the paper simultaneously.

Hand Methods.—The method of preparing stones for hand printing, which is still the lithographic method preferred by artists, has remained substantially unchanged since Senefelder's time. The materials and procedures of the 19th-century lithographer are duplicated in almost every respect by the contemporary hand printer. Three types of stone are used: blue-gray, gray and yellow. The latter, which is very soft, is for coarse work only. The stone is grained to provide an even texture for receiving the drawing. This is done by sprinkling a hard, powdered abrasive, such as flint or carborundum, on the stone, adding water as a lubricant and rubbing with another stone in a flat, rotating motion. After the graining is completed, the drawing is made on the stone or is transferred from a sheet of specially prepared paper. The stone is etched by brushing on a solution of gum arabic (acacia) and nitric acid; the solution also desensitizes the surface to, *i.e.*, lowers its affinity for, grease. Next the stone is rubbed with a solution of gum arabic, the drawing is washed off with turpentine and the stone is rubbed with asphalt (asphaltum) to strengthen the greasy areas. Finally, the stone is coated with water and inked for printing.

The printing is done on a press that exerts a sliding or scraping pressure. The pressure is exerted through a bar of wood that is immovably fixed at the top and is covered at the bottom by a strip of greased leather. The stone to be printed is covered with dampened paper and a flexible backing board and is placed on the press bed, which is then raised by a lever to make firm contact with the scraper. The printer moves the bed horizontally, and the paper is pressed against the inked stone by the sliding pressure of the scraper. When the scraper reaches the end of the stone, the bed is lowered and the backing board and the inked paper are removed.

Types of Plates.—There are four basic types of offset plates:

paper, albumin, deep-etch and bimetallic. Copy can be typed directly on special paper for printing on small office-type presses; such plates can produce 5,000 to 10,000 copies under average conditions. The albumin and deep-etch processes, which employ photographic techniques, are for longer runs. Albumin plates can produce up to 25,000 impressions; deep-etch plates are capable of several times this number. Bimetallic plates, which also are made photographically, are extraordinarily durable, being capable of printing more than 1,000,000 impressions. These plates are made from two different metals, one of which holds water and repels grease, while the other, which composes the printing image, attracts greasy ink.

Preparation of Copy and Plates.—Photolithography, since it is a duplicating process, requires material to reproduce. This material, which is known as copy, can consist of typographic matter, water colours, oil paintings, line drawings, hand lettering and photographs, either alone or in combination.

Copy is usually prepared as a paste-up that combines type matter with other line copy (black and white, such as line drawings). The type matter is taken from proofs ("repro proofs") of type that are made on high-quality proof presses especially constructed for reproduction ("repro") purposes. Type matter also may be taken from photocomposition. (See *TYPESETTING: Filmsetting*.) If photographs and other tone copy are to be included in the plate, their position and size are indicated on the paste-up by outline. A photographic negative is then made of the paste-up. This can be enlarged or reduced as desired.

A negative of the tone copy (photographs or wash drawings) is made separately in a camera that holds a half-tone screen, which breaks up the tone image into tiny dots. The half-tone negative is cropped to proper size; *i.e.*, the size that fits the space left for it on the paste-up. The line negative and the half-tone negative are "stripped" (fastened) together on a glass-topped layout table over a light. This unit (combination of line and half-tone negatives) is placed on a sheet of paper called "goldenrod" because of its colour; the goldenrod is translucent enough to be seen through on a layout (stripping) table but opaque enough to block light during exposure for platemaking. Openings are cut in the goldenrod paper where the negatives are positioned. The negatives are then fastened in place with opaque cellophane tape. The entire layout, or flat, is now ready for exposure on the thin, light-sensitive, albumin-coated metal plate.

The zinc or aluminum plate is grained or roughened to produce a foundation that will hold the sensitized coating firmly, hold water in the nonprinting parts and prevent the ink from spreading in the printing areas. The usual method of graining is to fasten the plate in a trough, cover it with water and an abrasive, such as sand or carborundum powder, and add a layer of steel marbles. The trough is geared to move horizontally and slightly up and down. This causes the marbles to roll and rub the abrasive into the plate, thus creating a fine, even texture. Plates are sometimes grained by chemicals—a hot solution of a monobasic salt of phosphoric acid, *e.g.*, monobasic sodium phosphate, for zinc and a hot solution of sodium hydroxide or aluminum potassium sulfate for aluminum. Most lithographic printers purchase and use pregrained plates rather than graining their own.

The grained plate is thoroughly washed and then counteretched, usually in a solution of acetic acid or hydrochloric acid. Counteretching removes dirt and metal oxides and sensitizes the plate to, *i.e.*, increases its affinity for, grease. Some shops etch the plate to make it more water receptive. The plate is now coated with a solution of albumin and light-sensitive ammonium dichromate. This operation is carried out on a machine that whirls the plate and spreads the coating evenly. The entire layout, or flat, is placed on the sensitized plate, and both plate and layout are locked in a vacuum frame, from which the air is withdrawn to ensure close contact for sharp photographic printing. The frame is exposed to strong light, usually from an arc lamp, which penetrates the transparent areas of the negative (type, lines and half-tone dots) and hardens the albumin underneath. The albumin under the opaque areas of the negative and the goldenrod paper remains soft and water soluble.

Exposure is often made on a photocomposing, or step-and-repeat, machine. This device produces multiple images of the original subject on one large plate. After an exposure is made, the subject is moved to the next position and again exposed. This procedure is continued as long as desired, or until the entire plate is covered. Since the machine is a precision instrument, with accuracy to one-thousandth of an inch, it is particularly valuable in colour work in which exactness of register is essential. All kinds of copy can be handled by this machine, which also is adaptable to all other photographic printing processes.

The exposed plate is then rubbed with greasy developing ink to strengthen the printing image. After the developing ink is washed off with water, which also removes the soft albumin, the plate is etched with a solution of gum arabic. This desensitizes the bare grained metal to grease and dissolves any albumin that might cling to the edges of the image. Cellulose gum (sodium carboxymethyl-cellulose), which often is substituted for gum arabic, produces a more durable printing surface. The plate is now ready for printing.

Plates made by the deep-etch process can be used for longer runs than plates made by the albumin process. The printing areas of deep-etch plates are slightly below the surface of the plate. These plates, therefore, hold more ink and are less subject to wear. This platemaking method differs slightly from the albumin process. The plate is sensitized in the usual way but in the vacuum frame is exposed behind a positive rather than a negative. It is then developed with a lactic acid solution to remove the unhardened coating. Next it is etched in the image areas to eat away the bare metal; the light-hardened film is not affected. After being washed with anhydrous alcohol to remove the etch, it is dried and covered with lacquer. After being developed in the usual way, the plate is scrubbed with water to remove the light-hardened film that covers the unetched portions. These unetched areas will hold water in printing, while the etched areas will hold the ink.

Printing.—Offset printing is done on a press that is composed, basically, of three rotating cylinders—a plate cylinder, to which the metal plate is fastened; a blanket cylinder covered by a sheet of rubber; and an impression cylinder that presses the paper into contact with the blanket cylinder. The plate cylinder comes in contact first with a series of moistening rollers that deposit a thin film of water in the granulations of the bare metal. A series of inking rollers then passes over the plate. The ink is rejected by the water-holding areas but is accepted by the greasy image, after which it is transferred to the rubber blanket. This inked image (type, drawings, half tones) is then offset to the paper traveling around the impression cylinder.

Decalcomania.—Decalcomanias are designs that are printed on specially prepared paper to form films that can be transferred to any surface. These films, which usually are called decals (transfers), are widely used for decorating and labeling any objects that cannot be run through a press. Decals are made in a variety of ways, depending upon the needs to be served. The regular decal applied to such objects as typewriters and trucks, for example, begins with a sheet of porous paper coated with a solution of starch, albumin and glycerin. The design that will be seen is printed first; several coats of opaque white, which will not be seen after application, are then added; and the decal is finished with a coat of water-soluble glue called "stickative." When the decal is moistened and applied to the object, to which it adheres, the moistened backing paper is removed, and the design becomes permanently affixed. The stickative becomes water resistant soon after application.

Decals applied to windows are printed in reverse order. The layers of opaque white ink are printed first and the design last in order to be seen when in contact with the glass. Decals for china and kitchen ranges are printed with mineral colours and are fired to resist heat.

Office Offset Presses.—Small offset presses, or duplicators, are used in offices, as well as in printing shops. They can print on sheets from 3 by 5 in. to 9½ by 14 in. at speeds from 3,000 to 6,000 impressions per hour. Paper-base plates, or masters, can be made by typing with a special ribbon or by drawing, writing,

tracing or lettering with a special pencil or ink. Corrections can be made with an ordinary eraser. For reproducing photographs, type and illustrations, zinc or aluminum plates are prepared as in the standard commercial offset method. However, these images appear rather gray because they require heavier inking than can be supplied by the duplicator's inking mechanism. The press is especially useful for printing office forms, sales letters and other matter on letterheads. Numerous kinds of paper-base plates have been developed for short or long runs, and plastic plates have come into use.

LITHOPONE, a mixture of barium sulfate, BaSO₄, and zinc sulfide, ZnS, in approximately equal molecular proportions used as a white pigment in the manufacture of paints. See PAINT: *Pigments*.

LITHUANIA (Lithuanian LIETUVA, Russian LITVA), the largest of the three Baltic republics of the U.S.S.R. It was independent of Russia during 1919–40, after which it became a constituent republic of the Soviet Union (LITOVSKAYA SOVETSKAYA SOTSIALISTICHESKAYA RESPUBLIKA, in Lithuanian LIETUVAS TARYN SOCIALISTINE RESPUBLIKA). It is 25,174 sq.mi. in area, had (1959) 2,711,445 inhabitants, and a density of population of 108 persons per square mile. The capital is Vilnius.

Physical Features.—Lithuania has a coastline on the Baltic about 50 mi. in length, and is bounded on the north and northeast by Latvia, on the southeast by the Belorussian S.S.R. and on the southwest by Poland and the Kaliningrad *oblast* of the Russian S.F.S.R.

The country consists mainly of Devonian rocks in the north-eastern half and Cretaceous in the southwestern half. Because of the thick deposits of glacial material in many districts solid geology bears little relationship to relief. The main features of relief are a central lowland, mostly below about 300 ft., drained by the Neman (Nemunas) and its tributaries in the south and by tributaries of the Latvian river Lielupe in the north, and two areas of morainic deposits, the Samogitian hills (Zhmudsk upland) in the northwest, and parts of the Baltic and Belorussian ridges in the southeast, heavily wooded and characterized by numerous small lakes. The lowland extends to the Baltic coast in the west, where the Neman enters the Kurisches Haff (Courland lagoon or Kurski Zaliv), almost cut off from the open sea by a long spit. Sand dunes occur along the shore. Nowhere do the uplands exceed 1,000 ft. above sea level, though several small districts are above 900 ft. and some areas are deeply dissected. In contrast to the broken uplands, parts of the lowland are flat and marshy.

Climate.—Because of its maritime location, Lithuania has a milder climate and is more humid than similar latitudes farther east (54° N.—56½° N.). The mean temperature for January is —5° C. (23° F.) in the central lowlands, but somewhat higher near the coast; the mean July temperature is about 16°–17° C. (62°–63° F.) over most of Lithuania. The coast remains virtually ice free. Mean annual precipitation exceeds 30 in. over much of the lowland.

Vegetation and Animal Life.—The natural vegetation of Lithuania is mixed coniferous and deciduous forest, but most has either been cleared for agriculture or cut for timber. About 23% of the total area is forested, more than two-thirds of it with coniferous species, mainly pine, the remainder deciduous species including

birch, aspen and alder. About 5% of the total area is marsh. Soils are mainly podsolized, but in the north there are some areas in which lime is abundant. Sandy soils of glacial origin are widespread and boulders deposited during the glacial period are an obstacle to farming.

Wild animal life in Lithuania is confined generally to smaller mammals, though wolves are occasionally found. Common fauna include hares, squirrels, foxes, otters and badgers. Birds include grouse and woodcocks, together with herons and cormorants in the coastal districts. In addition to seals, Lithuania has salmon and trout, and cod, plaice and herrings off the coast. (J. P. Co.)

The People.—Lithuanians within and outside Lithuania probably number more than 3,000,000. Jointly with the less numerous Latvians they form the Eastern Balts. They have preserved their language in a very archaic form. They differ anthropologically from the Western Balts. The latter were represented by the now extinct Prussians and Sudovians (Jatvingai or Jatwings), and had a still more archaic anthropological structure, which was closer to peoples of the Neolithic era and consequently also to the Early Germans.

The anthropological changes of the Lithuanians, and of the Eastern Balts in general, were probably caused by the absorption of the remnants of Lapps who were pushed southward by the Baltic Finns. The "Finnoi" located on the Ptolemaic map east of the Vistula, most likely in the middle part of the river basin of the Neman (Nemunas), were probably such a remnant. The Lithuanians are supposed to have originated in the upper part of the Dnieper basin and were presumably derived from the ancient Neurs. According to Herodotus they moved from the borders of the steppes toward the northern forests around 513–512 B.C.

The culture of the Lithuanians developed in the middle ages under the influence of the Russians and, later, under that of the Poles. The great majority of the people are Roman Catholic; there are minorities of Lutherans, Calvinists, Orthodox and Jews.

(See also BALTIC LANGUAGES; BALTS; LITHUANIAN LANGUAGE; LITHUANIAN LITERATURE.) (J. Cz.)

Population.—Of the total population of Lithuania (2,711,445 in 1959), 39% (1,045,965) was urban, but although this was a considerable increase over the 23% of urban dwellers in 1939, the average is appreciably lower than that in the U.S.S.R. which was, as a whole, 48%. The density of rural population is highest in the southeast and along the coast, and the largest towns are also in these areas. Vilnius (236,078) and Kaunas (214,348) are the largest, while Klaipėda (89,923, formerly Memel) is the principal seaport. Siauliai (59,722) in the north is the only other town with more than 50,000 people. In 1959, 79.3% of the total population of the republic consisted of Lithuanians, 8.5% of Russians and 8.5% of Poles, and there were small numbers of Belorussians, Jews and Ukrainians. (J. P. Co.)

History.—The Lithuanians belong to the Baltic group of nations, which included also the Old Prussians to the west and the Latvians to the north (see BALTS). In the 13th century A.D. the Old Prussians were defeated and partly exterminated by the German Knights of the Teutonic Order (*q.v.*), and Latvian Livonia was conquered by the Knights of the Sword, who in 1237 joined the Teutonic Order. The Lithuanians, however, resisted the German pressure, though Samogitia (Lith. Zemaitija), lying between Prussia and Livonia, was an object of German covetousness. To counteract the German threat, the Lithuanian tribes before the middle of the 13th century united under Mindaugas. Until then Lithuania was ruled by a confederation of the most powerful chieftains. He and his family were baptized in 1251; and two years later, in his capital (probably at Kernave on the Neris), he was crowned the first and only king in Lithuanian history by the authority of Pope Innocent IV. Mindaugas and his two sons were assassinated in 1263 and Lithuania remained officially pagan.

Traidenis, ruler of Lithuania from 1270 to 1282, was probably the founder of the dynasty known as that of Gediminas (*q.v.*), who began to rule in 1315. Though already under Mindaugas, shortly after the destruction of Kievan Russia by the Tatars, Lithuania had begun to expand eastward and southward to the

lands inhabited by Belorussians, it was Gediminas who really built the empire later known as historic (as opposed to ethnic) Lithuania. He made Vilnius the capital, as his letters of 1323 show. When he died in 1341, Lithuania's frontiers extended across the upper Dvina in the northeast, to the Dnieper in the southeast and to the Pripyet marshes in the south. The warlike but small Lithuanian nation could not colonize this vast territory, but maintained control over it because the ruling class had shown an undoubted political talent and a spirit of religious toleration.

Gediminas divided his empire among his seven sons. Soon, however, only two remained to continue their father's policy of expansion: Algirdas, with Vilnius as his capital, succeeded to the title of grand prince and undertook the defense of Lithuania against the Tatars and Muscovy; and Kestutis, with his seat at Trakai, reigned over ethnic Lithuania and defended it against the Teutonic Order. When Algirdas died in 1377 he left to his son Jogaila (Jagiello) an empire including Kiev, which had come under Lithuanian suzerainty in 1362; but Kestutis drove Jogaila from Vilnius in 1381 and proclaimed himself grand prince of Lithuania. Jogaila however captured Kestutis and his son Vytautas in 1382 and Kestutis died in prison; but Vytautas escaped and found sanctuary in the territory of the Teutonic Order. The German danger had become moreover especially serious because the knights had taken Kaunas in 1362, and Jogaila had promised them the whole of Samogitia to the Dubysa river in 1382. His Orthodox elder brothers tried therefore to convince him that Lithuania's interests lay in alliance with Muscovy and accession to the Orthodox Church, but his pagan younger brothers recommended a pro-Polish policy with acceptance of Roman Catholicism.

Polish-Lithuanian Union.—On Aug. 14, 1385, at Krievus (Krewo), Jogaila concluded with Polish ambassadors an agreement that he would forever unite Lithuania and Kievan Russia with the Polish crown if he could marry the 12-year-old Queen Jadwiga of Poland and become king of Poland himself. He went to Cracow, was baptized on Feb. 15, 1386, receiving the name Wladyslaw, married Jadwiga and, on March 4, was crowned king of Poland.

The Lithuanians outside the German-devastated Samogitia were baptized in 1387, and Jogaila granted the newly baptized boyars or gentry great privileges. In 1392 a reconciliation took place between Jogaila and Vytautas, who became lieutenant governor of Lithuania. A great warrior, Vytautas dreamed of conquering Moscow and destroying the Golden Horde. In 1398, to consolidate his rear, he confirmed the cession of Samogitia to the Teutonic Order; but on Aug. 12, 1399, on the Vorskla river, he suffered a defeat at the hands of the Tatars. His eastern dream having vanished, Vytautas became more inclined to accept Jogaila's policy of turning in concert against the Teutonic Order.

In 1401 new Polish-Lithuanian agreements were concluded at Vilnius and confirmed at Radom between Jogaila and Vytautas. The Lithuanian boyars promised that in the event of Vytautas' death they would recognize the king of Poland as the grand prince of Lithuania, while the Polish nobility accorded to Vytautas the title of grand prince of Lithuania and declared that if Jogaila died without an heir they would not elect a new king without consulting the Lithuanians. Almost immediately after these agreements, Vytautas supported the revolt of the Samogitians against the German rule. The knights replied with a military expedition against the grand principality. As the Poles and the Lithuanians were not yet in a position to risk a major war, Samogitia had once more to be abandoned (1404). Five years later, however, a new Lithuanian rebellion was in progress. The Order accused Vytautas of treachery and asked the Poles whether they would assist the Lithuanians again. In reply the grand master of the Order, Ulrich von Jungingen, was informed of the absolute solidarity between the two nations. War was inevitable.

The claim of the Teutonic Order to be combating Polish-Lithuanian "pagans" deceived many a western European knight into moving east to save Christianity, but in the decisive battle of Grunwald (Tannenberg), on July 15, 1410, the Polish-Lithuanian forces inflicted a crushing defeat on the Order. German supremacy in the Baltic countries was broken, though the first peace

treaty of Torun (Thorn), concluded on Feb. 1, 1411, was a moderate one. Samogitia returned to Lithuania until the death of Jogaila and Vytautas. On Sept. 27, 1422, however, the Order was forced to agree that Samogitia, by then Christian, was Lithuanian forever.

In the meantime, at Horodlo, on Oct. 2, 1413, a new pact of union was concluded between Poland and Lithuania. The principles of the union remained unchanged, but the autonomy of the grand principality was made permanent: after Vytautas' death the king of Poland would appoint another grand prince in agreement with the representatives of both countries. Vytautas died on Oct. 27, 1430, and Jogaila on June 1, 1434, but the latter was survived by the two sons he had by his fourth wife, Zofia (Sophia) of Alsenai (Holszanska), a Lithuanian princess whom he had married in 1422. His second son, Casimir IV (1447-92), king of Poland and grand prince of Lithuania, continued the struggle against the Teutonic Order and his efforts were crowned by the second treaty of Torun (Oct. 14, 1466) when the Order had to restore Pomorze (Pomerania) to Poland. After the death of Casimir a crisis arose in Polish-Lithuanian relations because the Lithuanian boyars elected Casimir's son Alexander as grand prince, while the Poles chose his brother John Albert. The Polish-Lithuanian personal union lapsed, but, on the death of John Albert in 1501, the Lithuanians insisted that their grand prince should be king of Poland too.

The Poles agreed and the senates of the two countries decided at Piotrkow that thenceforth the king of Poland should always be grand prince of Lithuania. The Teutonic Order was no longer a menace, but in the east there appeared another and greater danger. Ivan III, the grand prince of Muscovy, in 1480 assumed the title of sovereign of all Russia; and the major part of historic Lithuania was Belorussian-speaking. Belorussian was the language in which was written the statute of the grand principality adopted in 1529 (revised in 1566 and 1588).

On July 1, 1569, at Lublin, a common Polish-Lithuanian *sejm* or parliament transformed the personal union into a real one. In the course of the ensuing two centuries both the Lithuanian and Belorussian nobilities of historic Lithuania became polonized, but the two peasantries continued to use their own languages. On the eve of the second partition of Poland, the grand principality of Lithuania covered an area of 120,500 sq.mi. with a population (1791 est.) of about 3,850,000. There were about 1,420,000 Belorussians, 1,005,000 Poles, 770,000 Lithuanians, 385,000 Jews, 140,000 Russians, 95,000 Latvians (in Latgale), 30,000 Germans and 5,000 Karaims (Karaites). From the point of view of religion this population comprised 1,500,000 Uniates, 1,470,000 Roman Catholics, 250,000 Orthodox, 140,000 Raskolniki (dissidents from the Orthodox Church), 60,000 Protestants, 385,000 Jews, 40,000 Muslims (Polish or Belorussian-speaking Tatars) and 5,000 Karaims. (See also POLAND: History.)

Russian Rule.—While at the first (1772) and the second (1793) partitions of Poland only the Belorussian lands of the grand principality of Lithuania were annexed by Russia, at the third partition (1795) ethnic Lithuania suffered the same fate, the only exception being the province of Suwalki (Suwalki), the northern part of which was Lithuanian-speaking, which became part of the kingdom of Prussia. In 1806 Suwalki was incorporated into the duchy of Warsaw, which in 1815 was annexed by Russia. The congress of Vienna added to the style of the Russian emperors the titles of king of Poland and grand prince of Lithuania.

Under Russian rule historic Lithuania comprised six provinces: Vilnius (Vilna in Russian), Kaunas (Kovno), Grodno, Minsk, Mogilev and Vitebsk, with a governor general residing at Vilnius. When the Poles rose against Russia in 1830-31 the insurrection extended to the Lithuanian provinces before it was suppressed. The Polish rising of 1863 also spread into Lithuania and its repression there was particularly severe, 180 insurgents being hanged and 9,000 deported to Siberia.

On March 25, 1839, the Uniates were forced to join the Orthodox Church and the next year the Lithuanian statute was replaced by Russian codes. The tsarist government treated the "Territory of the Northwest"—as historic Lithuania was called after 1832—

as an integral part of Russia. From 1864 to 1905 the policy of russification extended to every domain of public life. It was forbidden to publish newspapers, periodicals or books in Polish or Belorussian, while books in Lithuanian could be printed if the Russian alphabet was used. Russian was the only language of teaching in the schools. The Roman Catholic religion was persecuted.

The Lithuanian people resisted russification because they remained faithful to ancient language and traditions and to their religion. By abolishing the serfdom of peasants throughout the empire in 1861, the tsarist government hoped that in the lands inhabited by non-Russian populations a wedge would be introduced between the peasants and the gentry and that the former, by acquiring the right to be proprietors, would be more easily russified. The Russians hoped that such a process would be easier in Lithuania proper where the landlords were mainly Poles. It was a miscalculation. Besides the clergy, a new Lithuanian intelligentsia of peasant origin began to emerge in the 1880s. In 1883 Jonas Basanavicius (1851-1927), a country doctor, launched the first Lithuanian periodical, *Aušra* ("Dawn"), published at Tilsit (then in East Prussia) and smuggled into Lithuania. *Aušra* was suppressed three years later, but in 1889 was replaced by *Varpas* ("Bell"), edited by Vincas Kudirka (1858-99), which continued to appear until 1904.

When the manifesto of Oct. 30, 1905, granted freedom of speech to the peoples of the Russian empire, two daily newspapers appeared at Vilnius, one Polish (*Kurjer Litewski*) and one Lithuanian (*Vilniaus Zinios*). On Dec. 4-5, 1905, a congress of about 2,000 delegates was held in Vilnius. The congress demanded territorial autonomy for Lithuania with a democratically elected *seimas*. The frontiers of the national Lithuanian state were to be drawn according to the freely expressed wish of the peoples concerned. Soon afterward the teaching of the Lithuanian language in schools was permitted.

Independence Attained.—During World War I the Germans occupied a great part of historic Lithuania. On Sept. 18, 1915, the German armies entered Vilnius. The German government authorized the gathering at Vilnius, on Sept. 18-22, 1917, of a congress of 214 Lithuanian delegates and the election of the 20-member *Lietuvos taryba* or council of Lithuania. The congress called for an independent Lithuanian state within the ethnic frontiers and with Vilnius as capital. As the leaders of the *taryba* (Antanas Smetona [q.v.], Steponas Kairys, Jurgis Saulys and others) rejected all idea of union or federation with Poland, the local Poles refused to co-operate with the *taryba*. On Feb. 16, 1918, the *taryba* proclaimed an independent Lithuanian state and the dissolution of all political connections that had existed with other nations. Germany recognized this on March 24 with the proviso of a "perpetual alliance" of Lithuania with the *Reich*. On July 11 the crown of Lithuania was offered to the Roman Catholic duke of Urach, Wilhelm von Württemberg, but the offer was withdrawn on Nov. 2, and the final solution of the question of the form of government was referred to the constituent assembly. Meanwhile, the supreme power was vested in a three-man presidium (Smetona, the Rev. Justinas Staugaitis and S. Silingas) which on Nov. 5 designated Augustinas Voldemaras (1883-1955) as prime minister of independent Lithuania. He formed a government on Nov. 11, 1918.

Lithuania was still under German occupation, but when the German troops had evacuated Vilnius, the city was entered on Jan. 5, 1919, by the Red army and a Communist Lithuania government, appointed by the All-Russian Central Executive committee on Dec. 23, 1918, was installed. It was headed by Vincas Mickevicius-Kapsukas (1880-1935). The Voldemaras government moved to Kaunas which, on Jan. 17, however, was also occupied by the Red army. The Germans remained in western Lithuania, which from the end of October to Dec. 15, 1919, was controlled by the German army under Rüdiger von der Goltz.

The Polish-Lithuanian Dispute.—Jozef Pilsudski, the head of the restored Polish state, proposed two alternatives for Lithuania. Either an independent state might be set up within purely ethnographic frontiers, that is, without Vilnius and its region, which was

largely Polish, or a larger state including Vilnius; but in the latter case some sort of a federal link with Poland would be indispensable. On April 20, 1919, the Polish army led by Pilsudski took Vilnius from the Red army, which enabled the Lithuanians to re-enter Kaunas. In the following summer the Polish forces moved to the Dvina river in the north and to the Berezina in the east. Against Lithuania they occupied the demarcation line fixed by the Inter-Allied committee presided over by Marshal F. Foch. This "Foch" line, adopted by the Supreme council on July 27, 1919, ran to the west of the Grodno-Vilnius-Daugavpils railways and more or less coincided with the eastern ethnic frontier of Lithuania. On July 12, 1920, when the Polish army was re-treating, the Kaunas government concluded in Moscow a peace treaty by which the Soviet Union "ceded" to Lithuania not only Vilnius, but also Lida and Grodno. After Pilsudski's final victory, the Red army, which occupied Vilnius on July 14, left it on Aug. 26 while the Lithuanian army entered the city. On Sept. 5, 1920, the Warsaw government appealed to the League of Nations. A Polish-Lithuanian conference met at Suvalkai and a partial armistice was signed on Oct. 7. Nevertheless Pilsudski ordered Gen. Lucjan (Lucien) Zeligowski to seize Vilnius, and this was done on Oct. 9. Zeligowski set up a government of central Lithuania. A new armistice, restoring the Foch line, was signed on Nov. 29, 1920.

Meanwhile the council of the League of Nations had made many attempts to settle the Polish-Lithuanian dispute. The last of the series was a Polish-Lithuanian conference which opened in Brussels on April 20, 1921, at which a plan for a Lithuania composed of two cantons, Kaunas and Vilnius, each with separate self-government, and federated with Poland, was recommended. But the Lithuanians wanted Vilnius without any ties with Poland. Zeligowski then ordered elections to be held in central Lithuania on Jan. 8, 1922, to a special diet of 106 members which would decide the future of the area in dispute; 55% of the inhabitants took part in the poll in Vilnius city and 65% in the province. On Feb. 20, 1922, the diet voted for the incorporation of the province with Poland. However, under the treaty of Versailles, the principal Allied powers had to determine the Polish frontiers that remained undefined. In the Polish-Soviet peace treaty signed at Riga (March 18, 1921), the Soviet government had declared its disinterestedness in the Polish-Lithuanian dispute. The council of the League of Nations, on Feb. 3, 1923, adopted a final resolution fixing a Polish-Lithuanian line of demarcation almost identical with the Foch line, leaving the decision as to the frontier to the Conference of Ambassadors in Paris. On March 15, 1923, the Conference of Ambassadors recognized the line of Feb. 3 as the final frontier between the two states. Lithuania, however, refused to accept this decision.

Foreign and Domestic Relations, 1919-39.—Lithuania was received into the membership of the League of Nations on Sept. 22, 1921. On Sept. 28, 1926, a Soviet-Lithuanian treaty of non-aggression was signed in Moscow. On Sept. 12, 1934, at Geneva, a treaty of good will and co-operation was concluded by Lithuania, Latvia and Estonia. Lithuania's relations with Germany were jeopardized by Nazi propaganda in the Klaipeda (Memel) territory.

In March 1935, at a trial of Klaipeda Nazis, most of the accused were found guilty of high treason. On March 17, 1938, Poland demanded of Lithuania the immediate opening of the frontier, acceptance of the cession of Vilnius and the establishment of normal diplomatic relations. Lithuania yielded to these demands. In February and May 1938 the Lithuanian government released the convicted Nazis and in October abolished martial law in the Klaipeda territory. On Dec. 11, at the election of the Klaipeda *Landtag*, the Nazis won 25 seats out of a total of 29. On March 21, 1939, Lithuania was presented with another ultimatum which meant the loss of its only port.

On April 4, 1919, Smetona became provisional president of the republic and Mykolas Slezevicius (1882-1939), a Democratic leader, succeeded Voldemaras as prime minister. On May 15, 1920, the newly elected constituent assembly met at Kaunas and its right-centre majority elected as president Aleksandras Stulginskis, the leader of the Farmers' union. On Aug. 1, 1922, a democratic constitution was adopted providing for a *seimas* of 80

elected for three years by proportional representation. As the *seimas* elected on Nov. 12, 1922, had no clear-cut majority, it was dissolved and a new election on June 5, 1923, restored the right-centre majority. The election of May 8-10, 1926, gave a majority to the left-wing parties. On June 7, 1926, Kazys (Casmir) Grinius, leader of the Peasant Populist party, was elected president while Slezevicius became prime minister. However, in the night of Dec. 16-17, 1926, a *coup d'état* took place in Kaunas. It was prepared by the army and backed by the small Nationalist party with the consent of the Christian Democratic party. Grinius resigned and Smetona was elected president; Voldemaras was again prime minister. On May 15, 1928, Voldemaras issued a new constitution which was to be submitted to a national referendum within ten years; but on Sept. 19, 1929, he was forced to resign and his Fascist organization, the Iron Wolf, was dissolved. The Nationalist party was then in full control. Voldemaras, attempting to regain power in 1934, was arrested and imprisoned for high treason committed with German support, but was granted an amnesty in 1938. The period of 1927-38 was that of restricted democracy. A new constitution, adopted on Feb. 12, 1938, was to provide the basis for a return to parliamentary institutions. A coalition government was formed with the inclusion of the Christian Democrats and Liberals, first between March 30, 1939, and Nov. 22, 1939, with Gen. J. Cernius as prime minister, and next with Antanas Merkys, but it had not enough time to reorganize the republic on a more solid basis.

Independence Lost.—A secret protocol to the German-Soviet treaty of nonaggression of Aug. 23, 1939, stipulated that in the event of a territorial and political rearrangement in the areas belonging to the Baltic states, the northern boundary of Lithuania should represent "the boundary of the sphere of influence of Germany and the U.S.S.R." When they began World War II the Germans made frantic efforts to induce Lithuania to attack Poland so that the former might thus become their ally and protégé. Lithuania chose to remain neutral and the secret protocol to the German-Soviet treaty of Sept. 28, 1939, revised the previous agreement by deciding that the territory of Lithuania fell within the sphere of influence of the U.S.S.R.

First Soviet Occupation.—On Oct. 10, 1939, a mutual assistance treaty was signed in Moscow, in accordance with which Lithuania was compelled to admit Soviet garrisons and to grant air bases. The Vilnius area was given to Lithuania, but was limited to 3,680 sq.mi. with a population of 549,000. (The province of Vilnius "ceded" by the U.S.S.R. in 1920 had measured about 12,450 sq.mi. and had a population of 1,275,000.) On June 15, 1940, however, Lithuania was confronted with an ultimatum demanding immediate formation of a "friendly" government. On the same day the country was occupied by the Soviet army. Smetona fled to Germany and later left for the United States. Merkys, Stulginskis and many other Lithuanian leaders were arrested and deported to Siberia. An obscure journalist, Justas Paleckis, became premier. A rigged election of July 14-15 produced a so-called people's *seimas* which, on July 21, unanimously requested the incorporation of Lithuania in the Soviet Union. On Aug. 3, 1940, the Moscow supreme soviet readily acceded to the request and Lithuania was declared a constituent republic of the U.S.S.R. In the night of June 14-15 next year 30,455 members of the Lithuanian intelligentsia (members of the national guard, civil servants, etc.) were deported to Siberia. Including other deportees and about 5,000 political prisoners executed at the time of the hasty departure of the Soviet forces, the country suffered during the first Soviet occupation a loss of about 45,000 people.

German Occupation.—A few days after the German attack on the Soviet Union (June 22, 1941) the whole of Lithuania was in German hands. On July 17, 1941, Hitler announced the creation of the "Ostland" province including the three Baltic states and Belorussia. The commissioner general for Lithuania was Adrian von Renteln who, on Aug. 5, dissolved the new Lithuanian government formed on June 23 on a basis of a broad national coalition. The Germans took over the co-operatives, corporations, banks, better farms and homes. A policy of German colonization was inaugurated and by July 1943 about 4,700 German families were

SOVPHOTO

SECTION OF THE VILIYA (NERIS) RIVER EMBANKMENT, VILNIUS, CAPITAL OF LITHUANIA

settled in Lithuania. The Germans executed almost all Lithuanian Jews. In April 1943, the Germans attempted a compulsory mobilization in the Baltic states, but in Lithuania the youth went into hiding. In March and April 1943, hundreds of leading Lithuanians were arrested and sent to concentration camps, where many died from hunger or tortures. At the same time Germany resolved to destroy Lithuania's cultural wealth. The universities and other institutions of higher learning were closed.

Second Soviet Occupation.—Vilnius was taken by the Soviet army on July 13, 1944, and Lithuania was again under Soviet occupation by the middle of October. The villages and cities suffered widespread devastation and massacres. All non-Communist organizations were immediately dissolved. The period of methodical sovietization and russification started. Fleeing before the Soviet armies, about 80,000 Lithuanians reached the western zones of Germany, but about 60,000 were rounded up in the eastern zone and sent to Siberia. In Lithuania, during 1945–46, about 145,000 Lithuanians were removed from their native land. The third mass deportation, ordered in connection with the forced collectivization of agriculture, took place on March 24–27, 1949, when about 60,000 Lithuanians were sent to northern Russia or Siberia. From 1945 to about 1953 hundreds of thousands of young Lithuanian men and women took refuge in the forests. In the first years of Soviet occupation the rural life was under partisan rule. There were many armed clashes between Lithuanian partisans and Communists until they were stopped by Soviet military and secret police forces. From 1944 Moscow systematically pursued the transfer of the Russian population on a large scale, particularly in the Vilnius and Klaipeda areas.

After the reconquest of Lithuania by the Soviet army Paleckis became chairman of the presidium of the supreme soviet and Mechislovas Gedvilas became prime minister; the latter was dropped in Jan. 1956 and replaced by Motejus Sumauskas. Antanas Snieckus was appointed first secretary of the Lithuanian Communist party. Founded in Vilnius in Oct. 1918, accepted as a component part of the Communist Party of the Soviet Union in Oct. 1940, the Lithuanian party, according to Soviet sources, had claimed more than 50,000 members in the early 1960s.

About 80,000 Lithuanians fled to Germany before the return of the Soviet forces. It was estimated that between 1945 and 1948 about 205,000 Lithuanians had been deported to Russia, but after 1954 many were allowed to return to their homeland.

The Roman Catholic Church had been left relatively free up to the end of 1946, but early in 1947 a wave of persecution began. According to an official Vatican source, by July 1950, out of 1,332 clergy left free until 1947, about 1,000 had been arrested and deported to Russia. Among them were Msgr. Pranas Ramanauskas, bishop of Telsiai, and Msgr. Teofilis Matulionis, bishop of Kaunadorys; they were permitted to return to Lithuania to die there in 1959 and 1961 respectively. The only bishop left in the country by 1953 was Msgr. Kazimieras Paltarokas, bishop of Panevezys, who also administered the diocese of Vilnius; he died in 1958. He was succeeded by Msgr. Julijonas Steponavicius who, however, was arrested in 1961. Although divided into six dio-

ceses, Lithuania had only one clerical seminary in Kaunas with about 50 seminarists.

The annexation of Lithuania by the Soviet Union is not recognized by the United States and western countries as a whole have not accorded *de jure* recognition. (K. SM.; MA. G.)

Administration.—Unlike the larger Soviet republics Lithuania is not divided administratively into *oblasts* but directly into 62 rayons. The supreme soviet, elected in 1959, comprises 209 deputies. In the early 1960s there were more than 4,250 primary, secondary and special schools with about 450,000 pupils. There were also 41 technical as well as 9 teacher training and 3 commercial schools. Places of higher education include 76 technical colleges, the Vilnius V. Kapsukas State university (founded 1579), the Lithuanian Academy of Sciences (1941) and pedagogical, music and art institutes. (X.)

The Economy.—In spite of steps to industrialize the republic, the economy remains predominantly agricultural. By the early 1960s the sown area exceeded 2,700,000 ha. (6,600,000 ac.) or more than 40% of the total area and this was being increased by the drainage of marshes. The principal types of cultivation are cereals, (44% of all sown area), fodder crops (40%) and potatoes (10%). Flax is the chief special crop of the region, and a little sugar beet is also grown. Rye is the principal cereal, followed by barley; wheat accounts for only about one-tenth of the cereal acreage. Perennial grasses occupy more than half of the land under fodder. Livestock farming makes up an appreciable part of the value of farm output. There is a much higher proportion of cows among the total head of cattle than in the U.S.S.R. as a whole and the emphasis is therefore clearly on dairying rather than meat production, though the republic also has a surplus of meat. There are more than 1,000,000 pigs, and sheep and poultry are also raised.

Industry in Lithuania lacks a basis of energy and mineral raw materials. Peat is the chief local source of fuel. Little hydroelectricity is produced, and coal and oil products have to be brought in from outside. A pipeline for natural gas from Dashava in the Ukraine reached Vilnius in Aug. 1961 and a branch line was to feed the thermal power plant at Elektrenai between Vilnius and Kaunas. At that time there was little heavy industry in Lithuania. Metallurgical and chemical industries were little developed. Production of timber, paper and cement is roughly adequate for local needs. The main branches of industry are textiles and engineering. Cotton, woolen and linen yarn and cloth are all produced, but Lithuania accounts for only 1%–2% of the Soviet total of these. The manufacture of machine tools is the principal branch of engineering represented in Lithuania, and in the early 1960s the republic accounted for about 6% of the national total. Other items manufactured include turbines, electrical apparatus, ships, cranes and precision instruments. Vilnius is the principal engineering centre but all the other large centres have some specialist engineering. Kaunas (woolen and silk) and Klaipeda (cotton) specialize in textiles, and linen goods are manufactured in several smaller centres. Vilnius, Kaunas and Klaipeda together account for 70% of all industrial production.

The republic is nearly self-supporting in food products, and it has a surplus of dairy products and flax. This surplus is offset by its deficiency in sources of energy and industrial raw materials, for which it depends on other regions of the U.S.S.R.

Lithuania has an adequate network of railways (1,290 mi.), and Vilnius and Klaipeda are important junctions. The road system is also of good quality by Soviet standards, the total length being 22,200 mi., of which 6,300 have a hard surface. The Neman is navigable for its whole length in Lithuania, but is frozen from early December to early March. Klaipeda is the chief port, and benefits from being ice free, in contrast to Soviet ports farther north in the Baltic. It is both a commercial and a fishing port. There is an airport at Vilnius.

LITHUANIAN LANGUAGE. The Lithuanian language, spoken by over 3,000,000 people, primarily in Lithuania, but also by numerous emigrants in the U.S., Canada, South America, Australia and Siberia, belongs to the Baltic branch of the Indo-European family. It did not become an official administrative language until 1918.

History.—Although not officially recognized, a literary language had been in existence since the 16th century. The earliest Lithuanian text, which is also the earliest Lithuanian document, is a translation of a Polish Protestant Catechism (1547) by Mosvydas (Mosvidius or Mažvydas, d. 1563). All Lithuanian writings of the 16th century are of religious character. The most important for the study of the language is the *Postilė* of 1599 by Mikalojus Daukša (1527-1613). The language differs in many respects from modern Lithuanian: longer endings (especially in the dative plural), a directive and an adessive case, strong Slavonic influence in vocabulary and syntax, differences in accentuation. Essentially the same characteristics are found in the language of the first half of the 17th century as represented by K. Širvydas (1579-1631), the first Lithuanian lexicographer.

The Lithuanian literary language, from its beginning through the 19th century, is not uniform, but is based on the dialects of the various authors. The dialects are divided into two main groups, Low Lithuanian or Shamaitysh (sometimes called Samogitian) and High Lithuanian or Aukštaitish. High Lithuanian is more archaic. Modern standard Lithuanian is based on the southern subdivision of the West High-Lithuanian branch, which is also the language of the Prussian Lithuanian pastor-poet Kristijonas Donelaitis (1714-80). In the 19th century, however, three literary languages were competing for recognition: (1) a Low-Lithuanian form, mainly represented by Dionyzas Poška (1757-1830), Simanas Stanevičia (1799-1848), Simanas Daukantas (1793-1864), and Bishop Matthew Valančius (1801-75); (2) the East High-Lithuanian poetic language of Bishop Antanas Baranauškas (1835-1902); and (3) the West High-Lithuanian language used in various underground publications as well as in East Prussia. The dialect used by Donelaitis was elevated to a standard language for all of Prussian Lithuania by the grammarian and lexicographer Friedrich Kurschat (1806-84) whose work was seconded by G. H. F. Nesselmann (1811-81) and August Schleicher (1821-68). In the 1880s, Jonas Jablonskis (1861-1930), born in Suvalku Naumiestis (not far from the former Russian-German border), became interested in his own native language while studying at the University of Moscow under F. Fortunatov (1848-1914), and began to study it with the help of Kurschat's and Schleicher's grammars. Jablonskis became the "father of the modern Lithuanian standard language," based on his own dialect.

Characteristics.—Lithuanian is highly inflected, with eight cases: nominative (*miestas* "city"), genitive (*miesto*), dative (*miestui*), accusative (*miestą*), vocative (*mieste*), instrumental (*miestū*), locative (*miestė*), illative (*miestan* "into the city"). In the modern standard language there are also remnants of a directive case (*galop* "toward the end") and an adessive case (*Dieviop* "with God"), both of which occur regularly in the texts of the 16th and 17th centuries. There are three numbers: singular, plural and dual (the latter optional). In the nominative singular the nouns, which are grouped into five declensions, have one of the following endings: -as, -is, -ys, -a, -ė, -i, -us, -uo. There are regularly two grammatical genders (masculine and feminine) with some traces of the Indo-European neuter in the adjective. No article is used with nouns. Adjectives appear in two forms: indefinite and definite. While otherwise very conservative, the language is unexpectedly progressive in the formation of the

comparative and superlative degrees of the adjectives and adverbs, there being no irregular comparison. The illative, directive and adessive cases are innovations which did not exist in the Indo-European parent language. While the Old Lithuanian (16th century) locative plural in -su is apparently inherited from Indo-European, the modern locative plural in -se is a former illative, i.e., the accusative case extended by means of a postposition.

The inherited verbal system is simplified to some extent. There are only four simple tenses: present, future (formed with -s, preterite or past, and imperfect or habitual preterite. Each of these tenses forms only an indicative. There is only one subjunctive (derived from the infinitive) for all tenses. The imperative is formed from the infinitive and the infinitive ends always in -ti (*eiti* "go," *duoti* "give," *daryti* "do," *dirbti* "work" etc.). Lithuanian, like Sanskrit, is rich in participles. There are two sets of participles (active and passive) for the present, future, and preterite; the imperfect has only an active participle. The passive participles are used in the formation of the passive voice. Like Russian and Polish, Lithuanian makes a rigid distinction between durative and perfective aspects, but it differs by not using the perfective aspect as a substitute for the future tense. The reflexive verb is highly developed. While in the main the Lithuanian verb continues the Primitive Indo-European *ō*-conjugation (thematic verbs), there are some traces of the *mi*-conjugation (nonthematic verbs). As in declension, there are three numbers also in conjugation (dual optional). On the other hand, there is only one form for the third person of the three numbers in each of the tenses.

Lithuanian is extremely rich in diminutives and endearing forms which are derived from nouns and adjectives alike. Diminutive nouns may express either smallness or affection or even contempt, while diminutive adjectives express intensification of the meaning. The strong emotional appeal of the diminutives supplies the language with effective poetic expressions and gives the Lithuanian folk songs their appeal. The vocabulary is immensely rich, abounding in onomatopoeic formations. The language is possessed of a continually productive creative power; no dictionary can ever include all Lithuanian words.

The word accent is free. It is not indicated in the orthography except in grammars and texts especially prepared for students. There is no general rule fixing the accent; nor does the main stress always remain on the same syllable throughout the whole paradigm. Furthermore dialects vary widely in their accentual systems. The standard accent of every Lithuanian word, with all indications necessary to ascertain its shifts in various paradigms, is given in the Lithuanian-German dictionary (see *Bibliography*, below).

Lithuanian is written in the Latin alphabet with 32 letters, some of which are conventional letters supplied with diacritic signs. All consonants, except *j* (= *y* as in "you"), have a hard or velar and a soft or palatalized pronunciation. There are roughly 11 different vowels (monophthongs), 6 short and 5 long, all of them clear cut without any diphthongization. There are also the diphthongs *ai*, *au*, *ei*, *ui*, *ie*, *uo*, and the combinations (treated as diphthongs) *al*, *ar*, *am*, *an*, *el*, *er*, *em*, *en*, *il*, *ir*, *im*, *in*, *ul*, *ur*, *um*, *un*.

LITHUANIAN LITERATURE. In the grand principality of Lithuania, which stretched in the 14th and 15th centuries from the Baltic to the Black sea, the official language was Belorussian and later Latin. In the 16th century the temporary spread of Protestantism, and thereafter the Counter Reformation, led to the writing of religious works in the vernacular. Lithuanian literature may be divided into four periods.

Early Period.—The first known Lithuanian printed book is the Catechism of M. Mažvydas (1547). Later there appeared the religious writings of J. Bretkūnas or J. Bretke (1535–1602). In 1701 the New Testament was published, and, in 1727, the entire Scriptures. Until 1700 books were mostly of a religious character. Among publications outside this category, the first Lithuanian dictionary, K. Širvydas' *Dictionarium trium linguarum* (1629), is noteworthy. To this period belong 85 authors and 70 publications, but these are now more of linguistic than strictly literary interest.

18th Century.—The 18th century produced more books of secular tendency, including grammars, dictionaries and the first collections of folk songs. The most significant work of the period was the poem of Kristijonas Donelaitis (*q.v.*), called "The Four Seasons"; it is written in hexameters, shows German influence and depicts village life throughout the year. The 18th century gave Lithuanian literature 61 authors and 198 printed publications.

19th Century.—New trends appeared in the 19th century. During its first half a national literary movement was fostered, mostly by graduates of Vilnius university; there was greater effort to create a Lithuanian literary language and, partly under the influence of romanticism, interest arose in the early history of Lithuania. Thus, alongside the patriotic poetry of Simanas Stanevičia (1799–1848) and Dionyzas Poška (1757–1830), the first attempts to write Lithuanian history were made by Simanas Daukantas (1793–1864). Among many other writers, the Rev. A. Strazdas-Strazdelis (1763–1833) is memorable as the author of religious and secular songs. Throughout there appears a surge of western influence, in the wake of the French Revolution.

This renaissance was continued by Bishop M. Valančius (1801–75), noted for religious and educational works and for imaginative prose on a more ambitious scale; further by Bishop A. Baranuskas (1835–1902), a poet whose greatest work is "Anykščių Šilelis" (1858–59; Eng. trans., *The Forest of Anykščiai*, 1956). In 1864 the Russian authorities forbade the printing of Lithuanian writings in Latin characters. Henceforth for 40 years books and periodicals were printed in so-called Lithuania Minor or Prussian Lithuania, then under German rule, and were smuggled across the frontier. The literature of this era seeks to revive the national consciousness and to rally the Lithuanians against the political control of Russia and the cultural influence of Poland.

The first modern Lithuanian periodical, *Aušra* ("Dawn"), founded in 1883 by Jonas Basanavičius (*q.v.*) and printed in Lithuania Minor, has given its name to the literature of the ensuing generation. Thus, Basanavičius, famous as a collector of folklore and as a publicist, is commemorated as the "father of the Lithuanian national movement." Vincas Kudirka (1858–99) was a leading publicist and short-story writer; one of his poems became the national anthem of Independent Lithuania. The Rev. J. Mačulis, who wrote under the pen name Maironis (*q.v.*), the most famous Lithuanian poet, noted both for dramatic and lyric poetry, has been called "the poet-prophet of the Lithuanian renaissance." Other distinguished names of the era are V. Storasta-Vydūnas (1868–1953), born in Lithuania Minor, philosopher, poet and dramatist; J. Biliūnas (1879–1907), a short-story writer of singular sensitivity; and the Rev. J. Tumas-Vaižgantas (1869–1933), a publicist and literary critic. Women writers included J. Žymantienė-Zemaitė (1845–1921), the most famous short-story writer of the period; S. Pšibilauskienė-Lazdynų Pelėda (1867–1926), writer of novels and short stories; and M. Pečkauskaitė-Šatrijos Ragana (1878–1930), who achieved a new perfection in the art of the short story.

20th Century.—In 1904 the prohibition of Lithuanian books in Latin characters was repealed and in 1918 the Lithuanians regained independence. Lithuanian writers continued the work of developing national culture, and in time more sophistication appeared in the works of younger authors.

V. Krėvė-Mickievičius (*q.v.*), the novelist and dramatist, was regarded by some as the greatest of Lithuanian writers. J. Baltrušaitis (1873–1944) achieved distinction as a lyrical poet in Lithuanian and in Russian. Other prominent names of the age were V. Putinas-Mykolaitis (b. 1893), novelist, dramatist and pioneer of the modern Lithuanian romance; B. Sruoga (1896–1947) and K. Binkis (1893–1942), both poets and dramatists; J. Savickis (1891–1952), novelist and short-story writer; F. Kirša (b. 1891), poet; P. Vaičiūnas (1890–1959), dramatist; I. Šeinius (1889–1959), novelist and short-story writer; and S. Čiurlionienė (1886–1958), novelist and dramatist.

The leading poet of the younger generation was B. Brazdžionis. Others were S. Neris (1904–1945), J. Aistis-Aleksandravičius, A. Miškinis, H. Radauskas, K. Grigaitytė, and G. Tulauskaitė.

The aesthetic moment was notable in the prose of A. Vaičiulaitis, and a highly individual and decorative style characterized that of N. Mazalaitė. Among other prose writers of note were the novelists J. Grušas, J. Jankus, V. Alantas, L. Dovydenas, P. Orinitaitė, the historical novelist F. Neveravičius, the literary critic B. Babrauskas and many others.

When Lithuania, in 1940 and again in 1944, was occupied by the Soviet Union, the writers remaining in the country were compelled to follow the line dictated to them by the Communists. Those working in the free world, about 100 in number, tried to further the development of the national literature. New modes of expression were successfully attempted in the philosophical poetry of A. Nyka-Niliūnas, in the idyls of J. Mekas and in the novels of M. Katiliškis.

Lithuania has a rich folklore, and, on the whole, the genres most favoured by Lithuanian writers have been the short story and the lyric, with their roots in the folk tale and the folk song.

LITKE, FYODOR PETROVICH, COUNT (1797–1882), Russian arctic explorer, geographer and naval officer whose influence on Russian science, geography in particular, was very great, was born on Sept. 28, 1797, in St. Petersburg. His grandfather (who spelled his name Lütke) had emigrated from Germany. In 1812 Litke joined the imperial navy and took part in a voyage around the world under V. M. Golovnin in 1817–19. During the four summers 1821–24 Litke commanded an arctic expedition which mapped the west coast of Novaya Zemlya and studied the adjacent southeastern part of the Barents sea. In 1826–29 he went around the world again, this time in command of a scientific expedition in the sloop "Senyavin," and made important surveys and collections in the Bering strait region and the western Pacific (Bonin and Caroline Islands). From 1832 to 1848 he was tutor to Tsar Nicholas I's second son Constantine. Litke was one of the founders of the Russian Geographical society in 1845 and was at its head from that time until 1873, with the exception of the seven years 1850–57 when he was admiral in command of the ports of Revel (Tallinn) and Kronstadt. He was president (1864–81) of the Imperial Academy of Sciences, taking particular interest in astronomy and magnetism. He wrote a large volume on each of his two major expeditions, and many scientific papers. The Geographical society instituted a Litke medal upon his retirement. He died on Oct. 20, 1882. (T. E. A.)

LITMUS, a mixture of dyes, the chief constituents of which are azolitmin and erythrolitmin. It is the oldest and most commonly used acid-base indicator. In an acid solution the dye turns red and in a basic solution it turns blue. Litmus was originally

prepared by the action of air, ammonia and an alkali carbonate on certain species of lichens (*Lecanora tartarea* and *Roccella tinctoria*) found in the Netherlands. It can be synthesized directly from β -orcinol.

The use of litmus as an internal indicator has been replaced in many industrial operations by various synthetic dyestuffs. For laboratory purposes litmus is usually used in the form known as litmus paper, an absorbent paper impregnated with the dye. When moistened with the solution under test, the paper changes colour. An alcoholic solution of litmus is sometimes used. A few drops added to the solution under test causes the whole solution to turn colour upon neutralization.

The pH range of litmus is 4.5 to 8.3.

LITOPTERN, any of the herbivorous, hooved mammals (ungulates) of the order Litopterna, an extinct group confined to South America during the long period of isolation of that continent from all others. Litopterns, derived from the most primitive hooved mammals, the condylarths, were abundant from the Paleocene to the Pliocene epochs and finally became extinct during the Pleistocene. They were represented very early in geological time by two distinct families, the Proterotheriidae and the Macrauchenidae.

Early proterotheriids were barely distinguishable from condylarths. By the Miocene Epoch the feet in some genera showed a remarkable specialization, the number of toes having been reduced from five to three and even to one. The foot of *Thoatherium* closely resembled that of the present day horse, but had progressed even further in the reduction of the lateral digits. Conservative members of this family persisted into the Pliocene, the time of extinction of this branch of the litopterns.

The Macrauchenidae reached a three-toed condition early in their history, but did not progress beyond this stage. The teeth of macrauchenids, in contrast to those of proterotheriids, developed high crowns with complex patterns of crests and ridges in the molars. The last genus known, *Macrauchenia*, was probably some-

what camellike in size and appearance. The skull was marked by a reduction of the nasal bones and development of a short proboscis. The neck and limbs were long, the body and tail short. Remains of these animals were first brought to light in Patagonia by Charles Darwin, and since his discovery, numerous specimens, including complete skeletons, have been found in the pampean deposits of Argentina.

During the late Pliocene and the Pleistocene a land corridor developed between North and South America, permitting invasion of the southern continent by herbivores and carnivores from the north. Concurrently some South American mammals pushed northward, but many of the once highly successful groups, such as the litopterns, already somewhat impoverished, were unable to survive the competition with their North American adaptive counterparts. Among the casualties was *Macrauchenia*, whose extinction marked the end of the once abundant litopterns. See also UNGULATE; PALEONTOLOGY.

See A. S. Romer, *Vertebrate Paleontology* (1945); W. B. Scott, *A History of Land Mammals in the Western Hemisphere*, rev. ed. (1937). (E. C. O.)

LITTLE ENTENTE, a mutual defense arrangement among Czechoslovakia, Yugoslavia and Rumania during the period between World Wars I and II. It was directed against German and Magyar dominance in the Danubian area and toward protection of the freedom and territorial acquisitions won by the member states in 1918. It was based upon the treaty of Aug. 14, 1920, concluded at Belgrade between Yugoslavia and Czechoslovakia, joined by Rumania in treaties with Czechoslovakia on April 23 and with Yugoslavia on June 7, 1921. By a treaty of Aug. 31, 1922, the three states undertook broader obligations of economic and political co-operation and by that of May 21, 1929, they agreed that the renewal of the treaty of alliance should be automatic at the end of each five-year period. At the same time they signed a treaty for the peaceful settlement of their differences in accord with the League of Nations model treaty of conciliation and arbitration of 1928.

Fascist Italy had been an enemy of the little entente from the beginning but the advent of Adolf Hitler to power in Germany on Jan. 30, 1933, challenged the whole structure of central Europe. On Feb. 16, 1933, the little entente states strengthened their bonds against this menace. Under the able leadership of Edvard Beneš, Nicolae Titulescu and Bogoljub Jevtic, as well as King Alexander of Yugoslavia, a veritable, if short-lived, diplomatic federation was constituted. The new pact created a permanent council composed of the three foreign ministers or their delegates to meet three times a year and to direct a common policy. A permanent secretariat was established, one section of which was to function at Geneva, the seat of the League of Nations.

The little entente took a lead in urging effective sanctions against Japan from 1931 to 1933 and successfully protested against Mussolini's proposal in March 1933 of a four-power pact to revise treaties without consultation with the smaller states of Europe in substitution of the League's processes. Though signed in June 1933 by Italy, Germany, Great Britain and France this project was not implemented. On July 4, 1933, the little entente signed a nonaggression agreement with the U.S.S.R.; on Feb. 9, 1934, Yugoslavia and Rumania joined Turkey and Greece to form the Balkan entente (*q.v.*); and on May 16, 1935, Czechoslovakia, motivated by the Nazi menace, signed an alliance with the U.S.S.R., following the French-Soviet alliance by two weeks. From its first meeting at Prague in Jan. 1934, the economic council of the little entente laid foundations for closer economic collaboration among the three countries, attempting to include in this work Austria and Hungary.

The assassination of King Alexander of Yugoslavia and Jean Louis Barthou, foreign minister of France, at Marseilles on Oct. 9, 1934, weakened the little entente. Prince Paul, the regent of Yugoslavia, supported Milan Stojadinovic, who dominated the country as premier from 1935 to 1939, in a policy of rapprochement toward Italy, Bulgaria and Germany, thus striking at the vitals of both the little entente and the Balkan entente. The vacillating foreign policy of France and the division between France and Brit-

BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

RESTORATION DRAWING (ABOVE) AND SKELETON CAST (BELOW) OF MACRAUCHENIA, A GENUS OF THE EXTINCT ORDER OF HOOFED MAMMALS, LITOPTERNA

ain in respect to Italy and Germany further weakened the little entente. At the Bratislava conference of Sept. 1936, Yugoslavia seemed determined to follow an independent policy and the council of the little entente virtually acknowledged the right of each of the member states to do so. The last conference of the council was held at Yugoslavia on Aug. 21, 1938. An unsuccessful attempt was made to conciliate Hungary by an offer of equality in armaments in return for the promise of a peaceful policy. Despite the reluctance of the Stojadinovic government, both Yugoslavia and Rumania, at the time of the Munich crisis, in accordance with the terms of their alliance, warned Hungary not to attack Czechoslovakia. But with the appeasing attitude of Great Britain and France, there was little question of the outcome. The Munich accord of Sept. 30, 1938, permitted Germany to annex the Sudeten area of Czechoslovakia, and destroyed the little entente by destroying Czechoslovakia, the keystone of the system. (Q. W.)

LITTLEHAMPTON, a seaport, seaside resort and urban district in the Arundel and Shoreham parliamentary division of West Sussex, Eng., at the mouth of the Arun, 14 mi. E.S.E. of Chichester by road. Pop. (1961) 15,699. Backed by the South Downs and with long sandy beaches, it caters to many vacationists every year and also has a harbour, accessible in good weather, with a small domestic and foreign trade. Timber, granite and fertilizers are imported and grain for seed is exported. Lifeboats are made in the local boatyards.

LITTLE MAGAZINE, the term applied to a certain kind of periodical published from 1890 through much of the 20th century. Little magazines flourished in the United States and England, though French writers (especially the *symboliste* poets and critics, 1880-c. 1900) often had access to a similar type of publication and German literature of the 1920s was also indebted to them. The name, probably derived by analogy from "little theatre," signifies most of all a nonprofessional and noncommercial manner of editing, managing and financing. A composite description of the little magazines' motives for existing and of their careers would most usefully take this form: a little magazine usually begins with the object of publishing literary work of some artistic merit which is unacceptable to commercial magazines for any one or all of three reasons—the writer is unknown and therefore not a good risk; the work itself is unconventional or experimental in form; or it violates one of several popular notions of polite moral, social or aesthetic behaviour. In addition, several little magazines were employed as direct forums for the advancement of entirely new ideas in literature such as those of the *symbolistes* of France and the imagists of the United States and England, or of social and political perspectives on a culture as in the leftist magazines of the 1930s in the United States and England.

As a consequence of these peculiarities, little magazines were frequently in the advance guard of modern literature. They lacked both the financial stability and the restrictive editorial controls of established commercial magazines and were likely for both reasons to take risks and make bold moves beyond the limits set by public taste at any given time. Frequently the little magazines advanced new developments in literature which were subsequently assimilated by a culture, the time lag usually being about two decades. Foremost in the ranks of such sponsorship of literature were *Poetry: a Magazine of Verse* (1912), especially in its early years under the vigorous guidance of Harriet Monroe; the more erratic and often more sensational *Little Review* (1914-29) of Margaret Anderson; a group of English magazines in the second decade of the 20th century, of which the *Egoist* (1914-19) and *Blast* (1914-15) were most conspicuous; and Eugene Jolas' *transition* (1927-38). In all but the last of these, a major guiding spirit was the U.S. poet and critic, Ezra Pound; he served as "foreign correspondent" of both *Poetry* and the *Little Review*, maneuvered the *Egoist* from its earlier beginnings as a feminist magazine (*The New Freewoman*, 1913) to the status of an *avant garde* literary review, and with Wyndham Lewis jointly sponsored the two issues of *Blast*. In this case, the little magazines showed the stamp of a single vigorous personality; similar strong and dedicated figures in little magazine history were the U.S. poet, William Carlos Williams (whose name appears in scores of little magazines,

in one capacity or another); the British critic and novelist, Ford Madox (Hueffer) Ford, editor of the *Transatlantic Review* (1924-25) and contributor to many others; and Gustave Kahn, a minor French poet but a very active editor associated with several French *symboliste* periodicals.

From the point of view of the writer, the little magazines rendered two essential services: their pages were accessible to him when he was still unknown, and they conducted campaigns designed to publicize and broadcast reputations in foreign countries. Both of these services persisted throughout little magazine history, though the stress upon them varied in the several stages of that history.

There were four principal periods in the general history of little magazines. In the first, from 1890 to about 1915, French magazines served mainly to establish and explain a literary movement; British and U.S. magazines, to disseminate information about and encourage acceptance of continental European literature and culture. In the second stage, 1915-30, when other magazines, especially in the United States, were in the vanguard of almost every variation of modern literature, a conspicuous feature was the expatriate magazine, published usually in France but occasionally elsewhere in Europe by young U.S. and British critics and writers. The major emphasis in this period was upon literary and aesthetic form and theory and the publication of fresh and original work, such as that of Ernest Hemingway (in the *Little Review*, *Poetry*, *This Quarter* and elsewhere), T. S. Eliot (in *Poetry*, the *Egoist*, *Blast*), James Joyce (in the *Egoist*, the *Little Review*, *transition*), and many others. The third stage, the 1930s, saw the beginnings of many leftist magazines, started with specific doctrinal commitments which were often subjected to considerable editorial change in the career of the magazine. *Partisan Review* (1934) was perhaps the best-known example of these in the U.S., as was the *Left Review* (1934-38) in England.

The fourth period of little magazine history began about 1940. One of the conspicuous features of this period was the critical review supported and sustained by a group of critics, who were in most cases attached to a university or college. Examples of this kind of periodical were, in the U.S., *The Kenyon Review*, founded by John Crowe Ransom in 1939, and in Great Britain, *Scrutiny*, edited by F. R. Leavis (1932-53). This and related kinds of support such as that of publishers maintaining their own reviews or miscellanies, represented a form of institutionalism which was radically different from the more spontaneous and erratic nature of the little magazines of earlier years. These magazines generally favoured criticism over creation and tended to stabilize and slow the growth of experiment in new literature. In the second half of the 20th century the prospects were, however, that the little magazine might at any time break out from newly established limits and recover at least in part its earlier freedom, if only as a protest against the dangers of too strict a standardization of the creative life.

LITTLE ROCK, the largest city and capital of Arkansas, U.S., the seat of Pulaski county, is on the south bank of the Arkansas river near the centre of the state at a dividing line between the mountains and the plains. It is the principal centre of commerce and manufacturing for the region. The population was 107,813 in 1960 and 128,929 in 1964. The population of the Little Rock-North Little Rock standard metropolitan statistical area (Pulaski county) was 156,085 in 1940; 196,685 in 1950; and 242,980 in 1960. (For comparative population figures see table in ARKANSAS: Population.)

Bernard de la Harpe, exploring the Arkansas in 1722, saw two conspicuous rock formations on the river banks, which he named *La Petite Roche* and *La Grande Roche* (or *Le Rocher Français*). Near the smaller rock was a settlement of Quapaw Indians, and La

Harpe made this his trading post. In later years, the "little rock" became the abutment for a railway bridge. The "big rock," on the North Little Rock side of the river and two miles upstream from the smaller formation, was the site of an army post and later became the location of a veterans administration hospital. In 1812 William Lewis, a hunter and trapper, built his home at the "little rock." In 1819 Arkansas became a territory with its capital at Arkansas Post. The site of Little Rock was surveyed in 1821, and the territorial capital was moved there the same year. Little Rock was incorporated as a town in 1831 and chartered as a city in 1836. A board-manager form of municipal government was adopted in 1957.

Little Rock was strongly anti-Union at the outbreak of the American Civil War, and the U.S. arsenal which had been strengthened by the federal government was seized by state authorities Feb. 8, 1861. In Sept. 1863, Gen. Frederick Steele's Union troops occupied the city, and a pro-Union government was set up. In the 1880s Little Rock became an important communication centre with the expansion of the state railways, and began to develop commercially and industrially. Industry in the greater metropolitan area experienced a marked and diversified growth in the 1940s mainly because of the proximity of raw materials and an adequate labour supply, and in the 1960s included cottonseed, wood products, light bulbs, roofing granules, watches and clocks, electric motors, nonwoven fabrics and food products. There are large railroad shops across the river, and bauxite mines just outside the city. The surrounding agricultural region produces large crops of cotton, alfalfa, potatoes, rice, fruits and vegetables. Within a short distance are vast stands of high grade timber and large deposits of coal, oil and natural gas. Other mineral resources in the region are marble, clay, flint, granite and barite.

Little Rock is noted for its three capitols, one of which served the territorial government. The meeting place of the territorial legislature between 1821 and 1836 is preserved in the Territorial Restoration, along with a block of buildings of the period, including the first print shop of the *Arkansas Gazette*, one of the first newspapers to be published west of the Mississippi. The Old state house, the capitol from 1836 until 1912, is a remarkable work of ante-bellum architecture. It is on the site of an Indian burial ground and has a commanding view of the Arkansas river. The Territorial Restoration and the Old state house, containing interesting authentic furnishings, are open to the public. The present state capitol is on a knoll near the business district and is flanked by other governmental buildings. It is of Arkansas marble and is patterned after the capitol at Washington, D.C.

Several state institutions are located at Little Rock, including the main branch of the state mental hospital, the schools for the blind and deaf; also medical units, a graduate centre and graduate institute of technology of the University of Arkansas. Other educational institutions include Little Rock university (1927), privately endowed; Philander Smith college (1868), a Methodist school for Negroes; the Arkansas Law school (1916), a private institution; St. John's seminary (1930), Roman Catholic; Arkansas Baptist college, for Negroes (1884); and Shorter college (established as Bethel institute in 1886), an African Methodist Episcopal school for Negroes at North Little Rock. Little Rock's Robinson Memorial auditorium houses a convention hall, lecture hall, committee rooms and a music hall seating 3,000 persons.

The metropolitan area has several parks, including MacArthur park, which surrounds the birthplace of Gen. Douglas MacArthur and is the former site of an army post at which the general's father was stationed. The 36 ac. of shaded grounds include a museum of natural history, a band shell and a museum of fine arts. The 200-ac. War Memorial park has a zoo, a swimming pool, a golf course, an archery range, an amusement park, a baseball park and the War Memorial stadium. The Arkansas Livestock show grounds at Little Rock is centred about the T. H. Barton coliseum. The Governor's mansion, at the opposite end of Center street from the Old state house, is a stately structure completed in 1950. The Georgian colonial two-story brick executive mansion is on a 6.25-ac. plot. The Albert Pike Memorial temple, state headquarters for Freemasonry, is a magnificent block-long structure in the downtown

area. Adams field, the municipal airport, is one mile from the main street. Veterans', Roman Catholic and Baptist hospitals are in the area. Camp Pike of World War I, renamed Camp Joseph T. Robinson in the 1940s, was an important military training centre. In the mid-1950s, the Little Rock air force base was built near Jacksonville.

Bishops of the Roman Catholic (St. Andrew's cathedral), Protestant Episcopal (Trinity cathedral), Methodist and African Methodist Episcopal churches maintain residence at Little Rock, and several other denominations have state headquarters and churches there.

From Sept. 1957 the city was the focus of world attention. The immediate issue was the right of nine Negro children to attend Central high school under a gradual desegregation plan adopted by the city school board, in accordance with the 1954 decision of the U.S. supreme court holding racial segregation in public schools as unconstitutional. Their attendance set off a series of legal battles and one of the 20th century's great tests of power between the federal and a state government. Gov. Orval E. Faubus ordered state militia to prevent Negroes from attending the school, but the state was enjoined from interfering by Pres. Dwight D. Eisenhower, who sent federal troops to maintain order throughout the year 1957-58. After various legal maneuvers, the city's public high schools were closed during the following school year, but were reopened in Aug. 1959 with several Negroes in attendance at Central and Hall high schools. City police dispersed a small mob of whites at Central on opening day, and token integration was accomplished without further incident. (K. W. P.)

LITTLE THEATRE MOVEMENT: see THEATRE: *United States: Community Theatre.*

LITTLETON, SIR THOMAS (c. 1407-1481), English judge, best known as the author of *Littleton on Tenures*, was born, it is supposed, at Frankley House, Worcestershire, perhaps in 1407, and certainly not later than 1422. He is said by Sir Edward Coke to have "attended one of the universities." He was probably a member of the Inner Temple where he lectured on the statute *De Donis Conditionalibus* (1285), which established the law of entail (*q.v.*). He appears to have been recorder of Coventry in 1450; he became sergeant-at-law in 1453 and was afterward a justice of assize on the northern circuit. In 1466 he was made a judge of the common pleas and in 1475 a knight of the Bath. He died, according to the inscription on his tomb in Worcester cathedral, on Aug. 23, 1481.

Littleton wrote his *Tenures*, a brief text on property, the first of the classical texts on English law not written in Latin and uninfluenced by Roman law, probably after his appointment to the common pleas, for the instruction of his son, Richard. It soon became the most celebrated treatise on English law and was acclaimed by Sir Edward Coke "the most perfect and absolute book that was ever written in any human science." Composed in law French, the *Tenures* was principally a scientific account of the English land law of the middle ages unmodified either by the doctrines of the chancellors, such as uses, or by later common-law innovations, such as contingent remainders and conveyances barring entails. Intended as a first book in law, it served countless generations of lawyers not only in England but also in America both before and after the Revolution.

The edition by Lettou and Machlinia of 1481 or 1482 was the earliest treatise on English law ever printed and among the first ten books to be published in London. An English translation by William Rastell appeared early in the 16th century. The division of the text into sections dates from the edition of William West (1581). The most famous form of the *Tenures* was Sir Edward Coke's *First Institute*, known as *Coke Upon Littleton*, the first edition of which appeared in 1628.

See E. Wambaugh, *Littleton's Tenures in English* (1903); W. S. Holdsworth, *History of English Law*, vol. 2, pp. 571-590 (1936). (S. Tr.)

LITTLE TURTLE (c. 1752-1812), American Indian chief of the Miami tribe, who became a popular hero among the settlers, was born in a village (later named after him) on the Eel river near Fort Wayne, Ind. Noted for military prowess and oratorical

ability, Little Turtle was one of the most important Indian leaders in the Northwest Territory. On Nov. 4, 1791, he led the Indians to a crushing victory on the Wabash river over federal troops under the command of Gen. Arthur St. Clair. In 1795, after the defeat of the Indians by Gen. Anthony Wayne at Fort Recovery and Fallen Timbers, Little Turtle, who was not in command at the latter battle, signed the treaty of Greenville, by which the Indians ceded to the United States much of Ohio and parts of Illinois, Indiana and Michigan. Thereafter he was a strong advocate of peace, and he successfully resisted the efforts of the Shawnee chief Tecumseh to induce the Miami to join his confederacy. He subsequently signed other treaties with the United States before his death at Fort Wayne on July 14, 1812.

LITTRÉ, MAXIMILIEN PAUL ÉMILE (1801–1881), French philologist and positivist philosopher, whose dictionary is one of the outstanding lexicographic accomplishments of all time, was born at Paris on Feb. 1, 1801. He was educated at the Lycée Louis-le-Grand, where he made friends with Louis Hachette and Eugène Burnouf. He then studied the English and German languages, and classical Sanskrit literature and philology. Littré intended to become a doctor, and had completed his studies when his father's death in 1827 made it necessary for him to begin earning money. He began to teach classics, and in 1835 became a regular contributor to the *National*, and eventually director of the paper. In 1839 appeared the first volume of his edition (completed 1862) of the works of Hippocrates, which secured his election the same year into the Académie des Inscriptions et Belles-Lettres. He also became a friend of Auguste Comte and popularized his ideas.

About 1844 he started working on his great *Dictionnaire de la langue française*. In the Revolution of July 1848 he took part in the repression of the extreme republican party in June 1849. His essays, contributed during this period to the *National*, were collected together and published under the title of *Conservation, révolution et positivisme* in 1852, and show a thorough acceptance of Comte's doctrines. Later he differed with Comte's more mystic ideas, but he concealed his differences. After Comte's death in 1858 Littré felt free to publish his own ideas in his *Paroles de la philosophie positive* (1859), and at still greater length in his work in *Auguste Comte et la philosophie positive* (1863).

About 1863, after completing his Hippocrates and his Pliny, he set to work in earnest on his French dictionary. In the same year he was proposed for the Académie Française, but rejected, because of the opposition of Msgr. Dupanloup, bishop of Orléans, who denounced him as the chief of the French materialists. He also at this time started with G. Wyruboff the *Philosophie Positive*, a review which was to embody the views of modern positivists. Literary work absorbed him until the overthrow of the empire compelled him to take a part in politics. He felt himself too old to undergo the privations of the siege of Paris, and retired with his family to Brittany, from which he was summoned by Léon Gambetta to Bordeaux, to lecture on history; and then to the senate to which he had been elected by the Seine département. In Dec. 1871 he was elected a member of the Académie in spite of the opposition of Dupanloup, who resigned rather than receive him.

Littré's dictionary was completed in 1873. An authoritative interpretation is given of the use of each word, based on the various meanings the word had held in the past. He died in Paris on June 2, 1881.

LITURGICAL MOVEMENT, ROMAN CATHOLIC. The 20th-century liturgical movement in the Roman Catholic Church embraces all the efforts to promote better understanding of Christian worship by clergy and laity and more active congregational participation in worship. Though such efforts have their roots in the 19th century, they are ordinarily dated from the pontificate of Pope Pius X (1903–14). While the movement is principally educational, it also extends to the revision or reform of liturgical services in order to achieve sincere and intelligent corporate worship by the laity. It is closely related to developments in biblical, catechetical, and ecumenical studies, as well as to the fuller role increasingly played by the laity in the Roman Catholic Church.

The English-speaking world was little affected by the movement until the 1920s, and even then the influence was limited. Its chief organ in English is the monthly *Worship* (originally *Orate Fratres*, from 1926); the principal organization in the English-speaking world is the Liturgical Conference (Washington, D.C.).

Official recognition of the development was first given by Pius X, who urged congregational participation in the sung liturgy and initiated several reforms: improvement of liturgical music, especially plainchant; daily communion and communion for young children; correction of the church calendar; and reform of the daily prayer or office. Little further official reform was introduced until the program was taken up again by Pius XII, but the popular movement had spread widely by then, largely through distribution of translations of the Roman missal for congregational use, the practice of dialogue Mass, and educational efforts aimed at a sounder spirituality based upon the Eucharist, understood as the action of the whole community of worshipers, and the other sacraments.

Pius XII encouraged the various levels of the liturgical movement, first by doctrinal pronouncements (encyclical on the church, the Mystical Body of Christ, 1943; encyclical on the liturgy; international congress on pastoral liturgy, Assisi, 1956), then by beginning a complete reform of rites through a special commission (1948). The chief reforms included evening Mass and a mitigated fast before communion, partial use of the vernacular languages in sacramental rites, the complete revision of the Holy Week services, and a provisional simplification of the church calendar and office. He also gave the strongest official impetus to congregational participation in the Mass and other services.

Pope John XXIII took up this movement by personal example and proposed that the second Council of the Vatican determine the general principles of liturgical reform. This was done in the council's first enactment, the Constitution on the Sacred Liturgy (promulgated Dec. 4, 1963), which insisted upon the universal need for promoting liturgical understanding and participation and also gave norms for revision of rites. Implementation of this constitution is the work of a commission named in January 1964 by Pope Paul VI for the whole Roman liturgy, but regional adaptations according to cultural traditions were to be accomplished by conferences or assemblies of bishops for their respective territories. The most striking reforms include the restoration of the cup to the laity on certain occasions and the introduction of the vernacular languages into services.

Summing up the findings of the popular liturgical movement, the second Vatican Council directed that the forms of worship should better express the communitarian nature of the liturgy, should take full advantage of the liturgy's didactic value (especially by simplicity and clarity of rites and by a fresh emphasis upon the place of the Bible in worship), and should remain open to development and regional adaptation in harmony with differing cultural and religious traditions.

McManus)

LITURGY, in the widest use of the term, refers to the public worship of the Christian church as expressed in formulas, rites and ceremonies. It is easier to trace the semantics of the word than to circumscribe the living limits of the thing called liturgy, as is particularly evident in the 20th century during the debates concerned with the liturgical movement. The encyclical *Mediator dei* of Pius XII (1947) equated liturgy with the priesthood of Christ as exercised by the church chiefly through the sacraments,

the sacramentals and the divine office. Christian liturgy, particularly its most important part, the mystery of the Eucharist, has taken different forms from the earliest period; the principle from which the differentiation sprang was originally neither linguistic nor dogmatic (as it became in the West at the Reformation) but geographical, as in the case of the great division into Eastern and Western rites.

This article deals, in necessarily summary fashion, first with the eucharistic rites of the Eastern churches and with the variants of the Latin Mass, then with the other sacraments and the sacramentals and finally with liturgical services in Protestant churches. It does not deal with the theology of the Eucharist, for which see *EUCCHARIST*. (P. MU.)

I. EASTERN EUCCHARISTIC RITES

Liturgy is the title most commonly used in the West to designate the eucharistic rite of the Eastern churches. The names these churches themselves apply to their celebration of the Eucharist represent three concepts: a holy and public function (*leitourgia*, Byzantine), sanctification or consecration (*qudasha*, Nestorians and Malabar Christians; *agiasmos*, Copts; *qedeshe*, Ethiopians) and oblation or sacrifice (*badarak*, Armenians; *qurbana*, Syrians and Maronites). In this part of the article, for simplicity's sake, the word liturgy is used throughout.

A. HISTORY

1. Development.—It took many centuries for the Eastern liturgies to reach their present state. After free improvisation in the first three centuries, written formularies brought stability to the basic structure, though creative activity and borrowing by one rite from another never entirely ceased. By the 7th century the main types were fixed, but development within each liturgy still remained possible.

The Christian liturgy has a double origin: the sabbath service

of the Jewish synagogue, composed chiefly of readings from Scripture, and the special institution of Jesus Christ at the Last Supper when he blessed bread and wine and gave them to his disciples, saying that they were his body broken for remission of sins and his blood shed for the salvation of the world. Serious disadvantages were caused by the linking of this double rite of benediction and communion to an actual meal (see I Cor. xi, 17-34), and before the end of the 1st century the Eucharist was separated from the meal and was soon attached to the synagogue service that the Christians held on Sunday morning, as Pliny the Younger remarks in his 96th letter to Trajan.

For a long period there was a clear distinction between these two parts, which were known to have a different origin and aim. Justin Martyr's first *Apologia* (c. 150) and Hippolytus' *Apostolic Tradition* (c. 217) show that the first part was omitted after the conferring of baptism or of holy orders; as late as the 6th century in a number of Palestinian monasteries the Armenian, Georgian and Syrian monks had their Bible lections each in their own language and in their own chapel before joining the Greeks in the main church for the celebration of the Eucharist.

2. Sources.—From the 4th century onward various sources give information about the liturgies of the different churches:

a. Actual formularies, such as the "Clementine" liturgy in the eighth book of the Apostolic Constitutions, the *Euchologion* of Serapion of Thmuis, the Greek liturgies of St. James, St. Mark, St. Basil and St. John Chrysostom, the Nestorian liturgy of the apostles Addai and Mari, the anaphora of the Der Balizeh papyrus.

b. The commentaries of Cyril of Jerusalem in his fifth mystical homily; of Theodore of Mopsuestia in his two last catechetical homilies; the interpretation of the *Testamentum Domini* and of the second book of the Apostolic Constitutions.

c. Scattered references in the writings of the Church Fathers and the canons of church councils.

Beginning with the 6th century, the most important sources for the historical study of the liturgies are the following: (1) for the Byzantine rite, the works of Maximus the Confessor, the canons of the Trullan council and the short commentary attributed to Germanus of Constantinople; (2) for the Syrian rite, the *Ecclesiastical Hierarchy* of Dionysius the Areopagite, the letter of Jacob of Edessa to the priest Thomas and the commentaries of George, bishop of the Arabs, of Moses bar-Kepha and of Jacob bar-Salibi; (3) for the Chaldaean rite, the 21st, 22nd and perhaps also the 17th homilies of Narsai of Nisibis, the canons of Isho'yabh I, the constitution of Isho'yabh III, the commentaries of Abraham bar-Lipheh and of Pseudo-George of Arbela and the "Questions and Answers" of Isho'yabh IV; (4) for the Egyptian rite, the 97th, 98th and 99th Arabic canons of St. Basil, the Arabic version of the *Testamentum Domini* and the *Euchologion* of the White Monastery in Egypt.

Later developments are the Byzantine proskomidia (the ritual preparation of the bread and wine) in the 12th century, new Syrian anaphoras composed up till the 15th century, and in the 18th century a new Maronite anaphora. As in other fields, here too the invention of printing had a stabilizing influence on liturgical formularies, rubrics and prayers.

B. STRUCTURE

The three original parts of the liturgy—Bible lections, consecration of bread and wine and communion of the consecrated elements—were increased, by the 4th century at the earliest, by two further actions: the ritual placing of the gifts on the altar before the great eucharistic prayer, and, after it, the fraction of the bread, the consignations, the commixture, the Lord's Prayer and the exclamation "Holy things for those that are holy" (*Sancta sanctis*). Finally, a preliminary office was everywhere added. An analysis of these six parts will show the ways in which the various rites differ.

1. Preliminary Office.—The Byzantine liturgy begins in silence, behind the closed doors of the iconostasis (chancel screen), with the preparation of the oblations on the side altar (prothesis); after covering them with a veil the priest censes them and says an offertory prayer over them. The deacon leaves the sanctuary

to cense the whole church and then invites the faithful to prayer. After this the choir sings three psalms with antiphons.

The Armenian liturgy, on the other hand, begins with a solemn hymn, during which the clergy go in procession to the sanctuary. After certain prayers the curtain is drawn across and then opened again after the preparation of the oblation. As in the Byzantine liturgy, the church is censed and a psalm is sung.

In the Nestorian rite the gifts are prepared before the faithful enter the church, and the service begins with the recitation of a *marmitha* (a division of the psalter, generally three psalms). During the singing of the *onitha* (anthem) of the sanctuary the bishop used formerly to enter and take his place with his clergy at the ambo in the centre of the church; there he placed incense in the censer, and the censing took place during the hymn "Thee, O Saviour of the world, we thank."

In the Syrian and Maronite rites the psalm singing takes place at the *sedro*, which includes an introductory prayer of praise, the chief prayer indicating the theme of the little office, a hymn of four strophes and a prayer for the acceptance of the incense; there is usually a censing. In addition, this little office is repeated; the preparation of gifts and the offertory prayer is joined to the first, and the censing to the second.

In the Coptic rite the priest says the Lord's Prayer with the faithful before entering the sanctuary, where he prepares the altar and then takes a piece of bread, which he wraps in a cloth and holds in his hands while walking round the altar three times, accompanied by the deacon carrying the wine. The priest then blesses the gifts, places them on the altar and says the offertory prayer over them. Next, he turns to the faithful and pronounces a formula of absolution from their sins. Finally he performs the censing, which is a long ceremony. The absence of psalm singing is striking here.

The Ethiopian rite, which is basically the same as the Coptic, begins with a ceremonial entry in which a deacon carries on his head a basket of bread from which the priest will choose the loaf for the Eucharist.

As the foregoing indicates, this preliminary part of the rite, which originally consisted only of psalm singing, was gradually enlarged, chiefly by the preparation of the offering and by the general censing.

2. Biblical Lections.—The second part of the liturgy is much simpler and more uniform. In the Byzantine and Armenian rites the little entrance with the Gospel book takes place first, corresponding to the entry of the bishop into the sanctuary. In the Nestorian rite the bishop goes to the ambo before the censing; in the other rites there is no trace of a similar ritual entry.

All rites include the *Trisagion*, the solemn threefold acclamation "Holy God, holy mighty, holy immortal," addressed by the Byzantines and the Nestorians to the Holy Trinity, by the Monophysite Armenians, Syrians, Copts and Ethiopians to Christ. The Monophysites add the words that caused so much controversy: "Who wast crucified for us." The acclamation concludes with the prayer "Have mercy upon us."

All the rites have at least two lections, one from the Pauline Epistles, the other from the Gospels. The Armenians, like the Byzantines up to the 8th century, add an Old Testament lection before the others. The Syrians sometimes have three Old Testament lections, the Nestorians regularly two (from the Law and the Prophets), while the Copts and the Ethiopians take their four lections from the New Testament (Pauline Epistles, Catholic Epistles, Acts of the Apostles, Gospels), sung toward the four points of the compass. The Gospel lection is plainly the most solemn one, preceded as it is by chants, censing and a procession.

The Armenians sing the Creed immediately after the Gospel. In all the rites the deacon invites the faithful to pray for the needs of all: for penitents, catechumens and the faithful.

3. Placing of the Gifts on the Altar.—The part of the liturgy that runs from this prayer to the beginning of the anaphora is less uniform, though containing elements common to all the rites. The Byzantines and Armenians first bring the gifts ceremonially to the altar in what is called the great entrance, with mention of the intentions for which the gifts are offered. Meanwhile the

choir sings the cherubic hymn ("We who in a mystery represent the Cherubim . . ."), which ends during the placing of the gifts on the altar, where they are censed. The Nestorians also take the gifts to the altar but with less ceremony; then follows an offertory prayer. From the procession of the gifts the Syrians have retained the processional hymn and the censing; the Maronites have kept the mention of intentions and the censing, which in fact takes place during the Creed. The Copts and Ethiopians omit this action, for they have already placed the gifts on the altar during the preliminary part of the liturgy.

It is worth noting the way in which the Nestorian and the Malabar priest approaches the sanctuary and the altar: as he comes toward the altar he makes three deep obeisances, and when he has reached it he kisses it three times—in the centre, at the right-hand corner and at the left-hand corner.

All rites contain the washing of the hands of the celebrant, the singing of the creed and the kiss of peace, but the order varies. The Nestorians retain also a prayer by the deacon, which, with its lists of names, recalls the diptychs recited in the early church at this point of the liturgy.

All rites also contain the following two actions before the great eucharistic prayer: the removal of the veil covering the gifts and the deacon's request to the faithful to stand upright, for the priest is about to begin the sacrifice.

4. The Anaphora.—The central part of the liturgy is sometimes called the anaphora (literally "offering"). It is easy to detect, beneath the later additions overlying its basic structure, the early parts that form it and that make it a logical whole, at least in the most widespread type, which is the Antiochene. This type lies behind the two Byzantine anaphoras, the Armenian anaphora, about 80 Syrian and Maronite anaphoras, the two Coptic anaphoras of St. Basil and of St. Gregory, and several Ethiopian anaphoras. After the introductory dialogue ("Lift up your hearts . . ."), the priest says a prayer, which can be called theological insofar as it praises and thanks God as the Creator of the universe and, in particular, of man; the prayer begins after the song of the angels: "Holy, Holy, Holy . . ." (the *Sanctus*), which the priest takes up, this time to exalt the work of redemption accomplished by the incarnate Word. This prayer, which can be called Christological in that it sometimes refers to incidents in the life of Jesus Christ, continues, often by a natural transition, with an account of the Last Supper. Here the priest repeats the words of Christ, in his name, with the intention of fulfilling his command "Do this in remembrance of me." Then comes the anamnesis ("memorial"; I Cor. xi, 24 f.), which recalls the death and resurrection of Christ and concludes with a formula of oblation whereby the actual bread and wine over which thanks have been given are offered to God. The Syrians, however, end with an insistent prayer for mercy. After thus offering these gifts, the priest asks the Father to send his Holy Spirit upon them so that, sanctified and changed by the Spirit into the body and blood of Christ, they may purify those who are going to communicate and make them enter into the communion of the Holy Spirit and into possession of the kingdom of heaven. This part is called the epiklesis. The great eucharistic prayer then continues by entering upon its longest part—the many intercessory requests for the saints, the living and the dead. The anaphora ends with a doxology.

Besides the Antiochene there are two other types of anaphora: the Nestorian and the Egyptian. The former is represented by the anaphoras of the apostles Addai and Mari, of Theodore of Mopsuestia and of Nestorius, as well as by the Maronite anaphora of St. Peter, which is today reduced to a Mass of the Presanctified. This type, which begins with the usual dialogue, continues with the theological prayer and after the *Sanctus* with the Christological prayer: the account of the Last Supper follows, then the anamnesis (where it exists), the intercessions, the epiklesis and the doxology.

The Egyptian type, known chiefly through the Coptic anaphora of St. Cyril, which is a slightly developed translation of the Greek anaphora of St. Mark, places the prayers of intercession between the theological prayer and the introduction to the *Sanctus*; further, the prayer after the *Sanctus* is not Christological but is a

rudimentary epiklesis; this does not prevent another epiklesis from appearing further on. The Egyptian type alone has the whole anaphora sung by the priest, although in the other rites the priest says most of the prayers in a low voice while the choir sings; in all rites, however, the actual words of institution are said out loud, and the faithful respond with "Amen."

Thus the three types of anaphora, as far as their main elements are concerned, differ chiefly in the position of the prayer of intercession. A point worth noting is the trinitarian form of the Eastern anaphora—the theological prayer, the Christological prayer and the epiklesis of the Holy Spirit—which appears very clearly in the Antiochene type.

5. Between Anaphora and Communion.—The part of the liturgy between the end of the anaphora and the communion looks forward to the latter. After a benediction and a litany, which is found in many rites, the Syrians and the Nestorians have the "manual rites," i.e., the fraction (breaking of the bread), the intinction (dipping the bread into the wine), the consignations (marking with the sign of the cross) and the commixture; the fraction and the other actions are performed for the sake of the commixture. The commixture, in fact, confirms that the body and the blood, present in the two separate kinds of bread and wine, belong to the one person of Jesus Christ. The Maronites, though keeping the prayer accompanying the fraction at this point, perform all the manual acts after the *Sancta sanctis*.

A series of prayers always occur in the same order: prayer before the Lord's Prayer, the Lord's Prayer itself, the embolism (i.e., expansion of the two last clauses of the Lord's Prayer), a prayer of inclination (i.e., said while all the heads are bowed) and finally the *Sancta sanctis* uttered at the elevation (lacking in the Nestorian rite) of the consecrated elements. The Byzantine, Armenian and Maronite rites place the manual acts after this series of prayers. The Coptic and Ethiopian rites have the fraction before this central series and the manual acts after it.

Each rite here has its own individual features. After the commixture in the Byzantine rite a little warm water is poured into the chalice; this *zeon* indicates the warmth of faith and of the Holy Spirit. The Armenians add to the elevation a ceremonial exposition of the body and blood of Christ. The Nestorians and the Malabars have the prayer of pardon before the Lord's Prayer, and the Malabars since the 16th century have placed the account of the Last Supper with the words of Christ at the beginning of the fraction. The Copts and Ethiopians have an absolution before the *Sancta sanctis* and immediately before the communion a magnificent profession of faith (*homologia*) in Christ.

6. Communion.—The last part of the liturgy is on the whole uniform in character. In all rites there are prayers preparing the priest and his deacon for communion while the choir sings. The faithful communicate by receiving, often in a spoon, a piece of bread dipped in the wine, save for the Copts and Ethiopians, who receive the bread and then the wine separately. What remains after communion is placed on the altar of the prothesis to be consumed after the service, or on the altar itself, in which case it is consumed immediately, and the ablution of the sacred vessels follows.

Thanks are given by a chant from the faithful, a litany from the deacon and a prayer from the priest. The concluding benediction and dismissal of the faithful immediately bring the liturgy to an end. In several rites the blessed bread (eulogia, antidoron) is distributed to the departing congregation, and the priest leaves the altar where he has celebrated the eucharistic sacrifice.

(A. M. RA.)

II. LATIN EUCHARISTIC RITES

Latin eucharistic rites may be divided into two groups: the Roman rite, which is that in almost universal use; and the others, whether obsolete or still extant. For a detailed exposition of the Roman rite, including its music, see MASS.

A. THE MODERN ROMAN RITE

1. Origin.—The uniform rite imposed in the 16th century on the Roman Catholic Church (with only a few exceptions) is called

the Roman rite. There are no detailed reports of the work of the commission that produced the *Missale Romanum*, promulgated on July 14, 1570, by Pius V, but modern scholars have traced the evolution of the greatest of the Western eucharistic rites, or to give it its common name, the Mass, through four significant turning points: (a) About A.D. 370 the changeover from Greek to Latin as the language of the Roman liturgy was complete. (b) About A.D. 600 there was a thoroughgoing reform by Gregory I the Great, aimed above all at clarifying the condition of the sacramentary (q.v.; the celebrant's Mass book). (c) About A.D. 950 reverse currents of influence from Germany began to influence the Roman Mass; these were Gallicanizing and newly created trends carried southward by the Frankish *ordines romani* (q.v.), and above all by the 10th-century Romano-Germanic pontifical (q.v.) from Mainz. (d) After A.D. 1000 this mixed development came to a close under Gregory VII and Innocent III; abbreviated liturgical books were drawn up for the Roman curia, and their use was spread everywhere by the friars.

The growing importance of Rome after the 5th century, when the pope became the only civil as well as religious authority in the city, led to the gradual increase of the influence of the local rite that developed there. The chief agents in its diffusion were the pilgrims to Rome, the Benedictine abbeys and the political power of the Carolingians. The "Roman" Mass, then, of the *Missale Romanum*, the standard rite in modern times, is composite both in its texts and its ceremonies and, broadly speaking, has been static—as a liturgy—since the 16th century. It is not the business of this article to discuss how suitable this rite is today as a world-wide (not merely Latin or European) liturgy, but it is possible, in the light of modern liturgical experiences and studies, to discuss its strength and weakness as a eucharistic rite.

2. Liturgical Structure.—As a liturgy, the Mass has a four-fold structure: (a) the communion of the Word of the Lord; (b) the offertory of the bread and wine; (c) the sacrifice; (d) the communion of the body and blood of the Lord.

Communion of the Word of the Lord.—This part is mainly scriptural, since all the readings are taken from Scripture, and the chants are almost without exception centos of scriptural passages. Critical studies of the lectionary (q.v.) have established the fact of a thematic unity in the readings for the greater feasts, whereas the readings for the seasons were originally chosen on a system of selection of continuous passages from the Bible. In the latter case, therefore, the aim was to unify not the parts of the same Mass but the Masses of a season. The hazards of time have altered the original arrangements in many details but have left this basic structure untouched. It would be artificial then to look for any one exclusive theme in the texts of a Mass that is the result of the latter system (the *lectio continua*).

The collect figures in this part of the rite as the first of the three symmetrical priestly prayers that close off three parts in the Mass: entrance, offertory and communion. These tightly packed Latin prayers are the despair of translators and commentators: their rich theological content can be rendered in English only at much greater length, and even then it is difficult for a listener really to grasp their full message.

The general decree *Rubricarum instructum* (1960) of the Congregation of Rites approved a new Code of Rubrics, which provided for a homily after the Gospel. To be liturgically appropriate, such a homily should arise naturally out of the texts of the liturgy of the day or out of the general liturgical context. In practice, however, this is often not feasible, since many dioceses use a prescribed course of systematic instruction, drawn up not on the liturgical lectionary but on a general catechetical basis. This course, though originally intended by Pope St. Pius X to be distinct from the homily, has in many dioceses taken the place of the liturgical homily at most Sunday Masses.

Offertory.—The offertory may be analyzed into four elements: (a) the bringing up to the altar of the Hosts and the wine; (b) their preparation as the matter of the sacrifice; (c) the offering of these *oblata*; (d) certain accompanying prayers. The third element, the offering of the bread and wine at this point of the Mass, calls for some theological comment. In the two earliest

witnesses to the Roman offertory (Justin and Hippolytus) there is no mention of a ritualization of the offertory; it is an action of simple practical utility by the deacons, without any external participation on the part of the faithful. Gradually, however, the faithful began to want to have some external part in presenting these offerings, and this was managed in one of two ways: either each member of the congregation came up to the altar and handed his loaf of bread and flask of wine to the clergy, or the latter came down into the nave to receive the offerings. There is no detailed information about the performance of either method, but the practice was established in Hippo (St. Augustine's episcopal see), Milan and Rome in the 4th century.

Some efforts have been made in the modern liturgical renewal to restore the offertory procession at Mass, but although this may be desirable as an external manifestation of the people's share in Mass, sometimes it has been misunderstood and has given a false emphasis as to who and what is offered up at Mass. The Mass is the renewal (though not the multiplication) of Calvary, and its central truth is that Christ in it offers himself to the Father. Bernard Capelle, in his *A New Light on the Mass* (Clonmore & Reynolds Ltd., Dublin; 2nd ed., 1961), points out:

From the spiritual point of view there are not many hosts, but one, one single bread as at the Last Supper, and it is offered by all. This bread is Christ, it is not ourselves and our life. The great spiritual value of the gesture of oblation by the faithful consists in the desire which it shows to offer up Christ individually and collectively, to offer the unique Victim by a movement of supplication on the part of the creature, powerless, needy and sinful, who has nothing to offer to God to glorify Him, and to obtain grace and pardon, except Jesus Christ. Understood in this way, the action of placing the host on the paten is full of spiritual significance, and it brings out the role played by the priest, stressing the fact that he is the representative of the assembled offerers for this essential act of presenting Christ to God. This does not exclude . . . the implication of complete submission of each individual, which is . . . inherent in every sacrifice. But we must not confine the significance of the gesture to that, nor declare that it is that directly. There is a hierarchy to be observed, and the distance between the two intentions is infinite. . . . Taken in the wrong sense, the offertory procession may be gravely prejudicial to the true understanding of the Mass.

The idea stressed by some liturgiologists that bread and wine, being the products of man's labour, are symbols of his life and activity, and as such are offered up at this point of the Mass, seems to give the initiative in offering to man's work, not to God's gift. Undoubtedly, man's work has a share in producing the bread and wine, but it is subordinate to the double gift from God: the gifts of nature (wheat and grapes, bread and wine), which are offered up to him, and which by the power of his grace are changed into heavenly gifts.

The secret, the concluding (silent) prayer of the offertory, usually presents the bread and wine as gifts from God in the order of nature, offered back to God by the church (with reference to the assembly gathered at Mass), but the bread and wine, by and large in the secrets, are seen in anticipation as Christ's own offering that will be brought about in them by the *veneranda commercia*, the "sacred exchange" of earthly for heavenly gifts.

Sacrifice.—In the Roman Mass the sacrifice is celebrated chiefly in the part that today is called the sacrifice and canon. Here one is confronted immediately by a liturgical fact—the silent canon—to which Catholics have grown so accustomed that it does not seem to them to call for comment. This custom of saying the canon in silence was introduced in different places over a long period of time, as congregations gradually lost the sense, vividly present in the early church, that they had an integral part to play in the corporate worship of the Mass. The silent canon, which had become universal in the Western church by the 16th century, was in fact made obligatory for the Roman rite by Pope Pius V's approval of the Roman missal of 1570.

It may be debated whether this silence is a strength or a weakness. The unmistakable cessation of all the familiar sounds in a congregation, which marks the moment of consecration, no doubt enhances the sense of mystery at the supreme moment of the eucharistic celebration. But considered in itself, apart from the Reformation controversies and in the light of the renewal of community values in worship, it seems to be a weakness to have the great thanksgiving and consecratory prayer so performed that it

does not come to the assembled faithful through the obvious human medium of hearing. It may be noted, however, that the *Instruction on Participation in the Mass* (1958) encourages (or rather inculcates) a sacred silence from the consecration to the *Pater noster*.

As a literary composition the canon is one continuous whole, couched in the noble liturgical Latin of the 4th century, and apart from one or two passages it is neither obscure nor complicated. The central portion is the scriptural narrative of the institution of the Eucharist, in which there is a deliberate symmetry of details between the two consecrations that is not found in the New Testament accounts of the Last Supper. The leading themes of the canon are contained in the "primary" passages, three of which precede and four of which follow the institution narrative. *Te igitur, Hanc igitur, Quam oblationem* are all prayers of offering. The group of four that follows the second consecration—*Unde et memores, Supra quae, Supplices te rogamus* and *Per ipsum*—is the richest in the canon, turning on the pivotal ideas of offering and remembrance. The "secondary" passages are five in all, two before and three after the consecration: The memento of the living and the *Infra actionem* before; the memento of the dead, *Nobis quoque* and *Per quem* after.

The basic religious fact in the canon is the sacrificial renewal of what Jesus did at the Last Supper; this is achieved by the words and gestures during the institution narrative, which in turn is set in a great thanksgiving prayer, beginning with the dialogue with which the preface opens, and ending with the great doxology: "Through Him, and with Him, and in Him, is to Thee, O God the Father Almighty, in the unity of the Holy Ghost, all honour, all glory, world without end."

The Communion of the Body and Blood of the Lord.—This is celebrated in the Roman rite after the canon. In the present rite, the faithful receive only under the form of bread; they come in procession to the altar rails, kneel down and receive the Host on the tongue, where it is placed by the priest. In 1962 the second Vatican council discussed the desirability of restoring, at least on certain occasions, the practice of communion under both kinds.

The postcommunion prayers are a rich repository of eucharistic faith and devotion. Prescholastic in composition, they emphasize the sacramental nature of Christ's presence rather than the fact of his presence; they stress the operative nature of that presence, not only in the sacrament but as an abiding influence in life; they bind communion as closely as possible to the mystery of the Mass.

3. The Community's Part in the Mass.—Attendance at Sunday Mass is obligatory for practising Catholics, and the ratio of worshipers to the total Catholic population is usually taken as the index of the vitality of local church life. But it may be questioned how far Catholic congregations really take part, as communities, in Masses they attend. The restoration of frequent and even daily communion under Pope St. Pius X at the beginning of the 20th century antedated the modern liturgical movement with its insistence on community participation. (See also LITURGICAL MOVEMENT, ROMAN CATHOLIC.) When in addition to physical presence at Mass there is added the practice of frequent communion, good people are often puzzled to know what more they are expected to do at Mass.

The *Instruction on Sacred Music and Liturgy* (1958) states as a basic principle: "Of its nature, the Mass requires that all present should participate in it, in their specific measure." This document codifies and authorizes at universal level practices of community celebration of Mass, which were unevenly distributed over the church according to the vigour or feebleness of the liturgical renewal in the different countries.

The lowest place on a list of forms of celebration rated according to community participation is what the Germans call *stille Messe*—a misnomer, in fact, since no Mass is fully silent. However, as a broad title, it may be applied to that form of celebration where the priest "says" Mass and is answered by the acolytes from within the sanctuary area, but where the general congregation, from beginning to end, do not say or sing anything. They do, however, fulfill the basic community requirements of being physically present and of performing certain gestures or postures in common;

e.g., rising for the Gospel, kneeling during the canon, going in procession to Holy Communion. In addition, of course, there is internal participation by each person present, to the best of his own ability.

The next highest place on the list is taken by the Mass in which the people "raise their voices in prayers and chants in common," even if these do not happen to be the liturgical texts of the Mass that is being celebrated.

A third form is "dialogue Mass," which, taking low Mass as the norm, allows the people to answer liturgically to the celebrating priest. There are four graded levels of participation possible in this form: (a) "if the people make the easier liturgical responses to the celebrant" (the acclamations such as *Et cum spiritu tuo*); (b) when the faithful also say the responses, which according to the rubrics are to be recited by the server, and, if Holy Communion be distributed within the Mass, say also the triple *Domine, non sum dignus*; (c) when the people recite aloud, in addition, with the celebrant, certain parts of the ordinary of the Mass—*Gloria in excelsis Deo, Credo, Sanctus-Benedictus, Agnus Dei*; (d) when the faithful say also with the celebrant parts from the proper of the Mass: introit, gradual, offertory and communion antiphons.

The nobler form of eucharistic celebration according to the instruction, which here echoes tradition, is solemn Mass; provision is made for graded participation by the faithful in the singing (no mention is made of their partaking in the ceremonies, which all take place in the sanctuary). Three levels of participation are apportioned according to their musical difficulty: the acclamations, the ordinary of the Mass and the proper of the Mass. The same norms are applicable to sung Mass, where there is a celebrating priest but no deacon or subdeacon.

4. Liturgical Language.—Any attempt at promoting community participation in the Roman rite today comes up against the problem of liturgical language. Latin is the language of the Roman liturgy; and whereas considerable incorporation of the vernacular into noneucharistic rites took place after the issue of bilingual rituals in 1947, nothing comparable was done for the Mass, though the case for the vernacular has been ardently, if not always prudently, championed on the continent of Europe, particularly since World War II. It should be noted that Latin is not exclusively the liturgical language for Mass, for the instruction of 1958 allows the use of the vernacular in the following instances:

(i) during low Mass, if it is customary, to add prayers or popular chants to the direct participation by the recitation in Latin of the correct liturgical texts; (ii) during low Mass—independently of any direct participation of the people—for common prayers and chants, provided these are in keeping with the different parts of the Mass; (iii) for the reading by a lector of the epistle and gospel.

It is not oversimplifying the issue in the debate to say that those who defend Latin are concerned for the visible unity of the world-wide church today and the historical unity with a centuries-old tradition, while those who favour a vernacular Mass do so in order to promote the active community participation of the faithful. The debaters often overlook a still more basic fact that, in liturgy, language is only a medium for a message whose biblical and spiritual content is often more remote than a dead language from modern man. A great renewal, lying at a deeper level than language, is needed here.

The debate on liturgical language held during the second session of the second Vatican council issued in a compromise, as may be seen in the relevant passages of the Constitution on Sacred Liturgy promulgated on Dec. 4, 1963. Latin is maintained as the liturgical language of the "Latin" rites, but for pastoral reasons greater scope is allowed in the use of vernacular(s) than hitherto (Constitution, No. 36, 1 and 2). The supplanting of Latin by the vernacular is permitted at three points of the Mass: the readings; the "Prayer of the Faithful"; those items of the liturgy which pertain to the people, as distinct from those said or sung by the priest (Constitution, No. 54). It should be noted that the "Prayer of the Faithful"—to take place after the Gospel with its homily—is a restoration by the council of a practice long obsolete. The constitution also allows for "a more extended use of the mother

tongue within the Mass" appearing desirable in some parts of the world (Constitution No. 54) and provides the steps by which it may be brought about (No. 40). A new departure in ecclesiastical procedure is to be seen in the application of this constitution: the executive power for enforcing the constitution is vested in the various national episcopal conferences.

5. Roman Rite and Paschal Mystery.—A highly significant renewal in the Roman rite is the restored order for Holy Week promoted by the decree *Maxima redemptionis* (Nov. 16, 1955). This not only restored the services to the time of the day corresponding to the biblical events (evening Mass on Holy Thursday, afternoon ceremony on Good Friday, midnight vigil on Holy Saturday) but emphasized the meaning of the rites as saving mysteries (not merely as historical souvenirs) by subordinating all the other rites to that of the Easter vigil. Particular care was taken to provide for participation by the people and to eliminate useless doubling of readings, prayers and roles.

The new calendar clearly marked the primary importance of the temporal cycle in the liturgical year and the place of Sunday in the week. Both these facts reinforced the importance of Easter and of the paschal nature of every Mass.

6. Roman Rite and Modern Church Architecture.—Many thousands of new and restored churches have been built all over the Catholic world in the mid-20th century (see RELIGIOUS ARCHITECTURE). Those that are most successful liturgically have been those that provide for active community celebration, with the faithful well deployed round a sacrificial altar in a setting redolent of the paschal mystery. The altar should represent the place of encounter of God with man in Christ; it is the focal point of the church, and nothing should distract from its importance. Since the priest is the human mediator for the people to God, there should be the maximum contact between him and the congregation. This ideal of community participation was successfully realized in a church designed by Dominikus Böhm at Ringenberg, in Germany, in 1935. Here the people sit on three sides of a free-standing altar, and the sanctuary is almost entirely surrounded by a communion rail. Other modern churches that satisfy the demands of the liturgy are the church of Basel-Riehen in Switzerland, designed by Fritz Metzger in 1950, and the church of St. Joseph Haslach, in Germany, designed by Hans Schädel in 1958.

But in bringing to the fore the principle of the people's share in the celebration of the Eucharist the architect must not lose sight of a complementary principle: the hierarchical nature of the liturgical assembly, whereby the distinction between the sacerdotal space (the sanctuary) and the congregational space (the nave, must be made manifest in the interior design of the church.

In modern church architecture, the position of the baptistery assumes considerable importance. Since baptism is the sacrament of entry into the Mystical Body, it is fitting that the baptistery be located in a prominent position near the entrance of the church. Good church architecture should respect the hierarchy of sacred values: side altars should be erected only where strictly necessary, objects of devotion should not be multiplied and, in general, the furnishing should be dignified and restrained. The pulpit should be situated in the sanctuary area of the church, not in the nave; in this way the preaching of the Word is seen to be an integral part of the liturgy of the Mass. (P. Mu.)

B. OTHER LATIN EUCHARISTIC RITES

Thanks to the tenacious conservatism of certain ecclesiastical provinces and religious orders, something of the rich diversity of liturgical practice that was once a feature of the Western, no less than the Eastern, Church has been maintained to the present day. A proviso in the bull *Quo primum tempore* of Pope St. Pius V (which made the missal of 1570 the exemplar for the whole West) saved from extinction the rites of those religious orders and dioceses where a continuous liturgical tradition of at least 200 years had been maintained. In modern times the church not merely tolerates these traditional rites: it takes positive steps to ensure their continuity.

There is no space to treat here the great Western liturgies that have disappeared in the course of the centuries, except for the most

important of them, the old Gallican rite, which existed until the end of the 8th century, when it was abolished by order of Charlemagne and replaced by the Roman. The other rites treated below are still in limited use.

1. The Gallican Rite.—It would be unwise to generalize about the liturgy of early Christian Gaul, since there was considerable diversity of practice from province to province and even among local churches. Moreover, it is known only at a late stage of its development (end of the 7th century) when it had become strongly marked by Spanish influence. The liturgical sources from which a reconstruction of the ancient Mass *ordo* can be attempted were nearly all compiled in Burgundy. The chief of these sources is a detailed exposition of the Mass rite contained in two letters of the Pseudo-Germanus (c. 800).

As to the origin of this rite there is still disagreement among scholars. It is certain, however, that it could not have been simply an importation from the East. It is clear from the little that is known of its development that the numerous Eastern elements were introduced only in the final stages of its formation.

The chief characteristic of the Gallican Mass rite was that, unlike the Roman Mass with its fixed canon, it provided a complete new prayer formulary for each feast of the calendar. The eucharistic prayer was thus made up of a series (more or less stable) of variable prayers grouped round the words of institution. In marked contrast, too, with the restrained Roman rite was the prolixity of the prayers and the dramatic quality of the ceremony.

The pattern of the Mass *ordo* may be summarized as follows: A series of chants, including *Trisagion*, *Kyrie eleison* and the canticle *Benedictus*, preceded the readings. There were three readings: the first taken from the Old Testament Prophets, the second from the Pauline Epistles or Acts and the third from the Gospel. This last, which had the character of a triumphal procession, was surrounded with magnificent ceremonial. After the homily the deacon chanted prayers for the people, using a form of diaconal litany that was common in the East. The offertory rite also included a splendid and majestic procession in which the sacred ministers carried the oblations to the altar during a chant known as the *Sonus*. It is noteworthy, however, that the faithful had no part in this ritual offering. Their gifts of bread and wine must have been left at the sacristy before the celebration of Mass. Two other points of difference from Roman practice deserve mention: the memento of the dead was inserted before the offering of the *oblata*, whereas in the Roman rite it comes after the consecration; and the kiss of peace was given before the beginning of the eucharistic prayer, not before communion as in the Roman Mass.

As stated above, the Gallican rite had no fixed canon. The eucharistic prayer opened with the *Contestatio*, a prayer corresponding to the Roman preface. This was followed by a short prayer, the *Collectio post sanctus*. The words of institution were probably said in a low voice: the actual formula used has not been preserved in the manuscripts. The prayer *Post secreta*, which followed, did service both as an anamnesis and an epiclesis. The rite of the fraction of the Host was carried out according to an intricate symbolism: the earlier practice was to arrange the particles in the form of a cross. The *Pater noster* was inserted after the fraction (another divergence with Rome, where it comes immediately after the conclusion of the canon). As was the custom in all the Western rites up to the end of the 4th century, a special blessing of the people preceded the distribution of Holy Communion. The sacrament was for a long time received under both kinds, the men receiving the Host in bare hands, the women in veiled hands. Two short prayers of thanksgiving, the *Post eucharistiam* and *Collectio*, followed. The deacon then dismissed the people, and the ceremony was concluded.

2. The Old Spanish or Mozarabic Rite.—This rite is known, although less appropriately, as Mozarabic (from *mustarib*, meaning under Arab influence) because it lasted longest in the provinces dominated by the Muslims. Its liturgy, in its essentials, was drawn up and unified before the Moorish invasion of 711; i.e., during the Visigothic period. In 1085 the rite was suppressed under Pope Gregory VII and was replaced by that of Rome, diffused

especially by the Benedictine monks of Cluny. An attempt to restore the traditional rite was made by Francisco Cardinal Jiménez de Cisneros, archbishop of Toledo, who commissioned the publication of a missal incorporating the Mozarabic Mass rite (1500). The rite is maintained only in a chapel of the cathedral of Toledo, where it is carried out daily by six chaplains.

The Mozarabic rite presents the closest affinity with the Gallican rite, upon which it exerted a considerable influence. As performed today, it contains many elements that are very late additions. The essentials of the ancient tradition, nonetheless, have been faithfully preserved.

There are normally three lessons at Mass, from the Old Testament, the Epistles or Acts, and the Gospels. During Lent and on fast days there are four lessons, the extra one being chosen from the Old Testament. The offertory prayers are borrowings from the Roman liturgy. The bread and wine are offered separately, but before offering the chalice the celebrant takes it in his hand and blesses it. The offering of bread and wine by the people, which formed part of the old Mozarabic rite, has disappeared from the Mass. As in the Gallican rite there is no fixed canon or eucharistic prayer; instead there are a series of seven variable prayers. It is in this central portion of the Mass that the Mozarabic rite has best preserved its identity; as early as the 7th century St. Isidore commented on these seven prayers.

A commemoration both of the living and the dead has its place after the offertory. The eucharistic prayer begins with the *Illatio* (Gallican *Contestatio*, Roman preface). For the consecration of the bread and wine the Roman formula is used. On certain days the creed is chanted immediately before the fraction of the Host. The latter rite has retained its ancient symbolism—division of the Host into nine particles arranged in cross form, each particle representing a mystery in the life of Christ. The *Pater noster* is said by the celebrant alone, but the people answer, "Amen," after each petition. The commixture comes after the *Pater noster* and embolism and is thus separated from the fraction. There is a threefold blessing of the people before communion. The Mass concludes with a short thanksgiving prayer followed by the dismissal.

3. The Ambrosian Rite.—The name is derived from St. Ambrose, 4th-century bishop of Milan, where this rite is practised. It is also known as the Milanese rite. The problem of the origin of this rite has not been finally resolved. The theory of L. Duchesne that the Gallican rite originated in Milan, whose bishops had borrowed it from the East, has now little support among scholars. It is not clear whether it should be classified with the Gallican or with the Roman type.

The framework of the liturgy is probably Roman. St. Ambrose in his treatise *De sacramentis* maintains that he followed the Roman rite while tolerating a number of local usages and traditions. It is now believed that in certain of its features the Ambrosian rite has preserved a more ancient form of the Roman Mass *ordo* than that found in the official Roman liturgy. The Mass also contains a number of Gallican usages: it is possible that these were introduced into the rite during the exile of the Milanese bishops at Genoa (570–641). The system of readings corresponds with the Gallican, and there are some Eastern features.

Although the Milanese rite has been progressively romanized, it has never lost its identity. St. Charles Borromeo, 16th-century archbishop of Milan, was its most vigorous champion. In 1902 a typical edition of the missal was published, which is that in use today. The following are the chief individual features of this rite that differentiate it from the Roman: (a) three readings (the first normally from the Old Testament); (b) after having greeted the people with *Dominus vobiscum* before the offertory, the priest says the *oratio super sindonem*, a prayer that may once have formed part of the Roman Mass formulary; (c) survival of the old Roman offertory procession, in which the offerings of bread and wine are presented by two old men (the *vecchioni*); (d) the creed placed after the offertory; (e) a number of textual variants in the canon of the Mass; (f) the celebrant washes his hands before the consecration; (g) the fraction preceding the Lord's Prayer and accompanied by a chant called *Confractorium*; (h)

after the embolism the priest greets the people with the blessing *Pax et communicatio*; (*j*) no *Agnus dei* except in requiem Masses; (*k*) a special formula for the distribution of communion; (*l*) a threefold *Kyrie* before the final blessing.

4. The Rite of Lyons.—This is no longer held to be a survival of the old Gallican liturgy; on the contrary, it is simply a variant of the Roman rite that, in some respects, is "more Roman than that of Rome." It represents the Roman liturgy at a certain stage of its development and took shape during the episcopacy of Leidrade (798–814). This bishop, by order of Charlemagne, undertook the reform of the liturgy in his see, modeling it on that of the palatine court at Aachen; *i.e.*, on the Roman-Carolingian liturgy as then fully evolved and established. Thanks to the tenacity of the chapter of the primatial church, this new rite remained intact throughout the middle ages, indeed for nearly 1,000 years. With the appearance of the reformed Roman missal (1570), certain modifications were introduced to bring the Mass rite into line with the new legislation, but nothing of importance was sacrificed. It was not until the troubled years of the 18th century that the survival of the Lyons rite was seriously threatened. For a while the missal was suppressed and a neo-Gallican one placed in its stead. After a prolonged struggle the independence of the rite was finally secured when, in 1903, the Congregation of Rites approved a new edition of the Lyons missal, which, while not reflecting the full riches of the traditional liturgy, nonetheless embodied some of its most characteristic features.

The peculiar splendour of this rite is best manifested at a pontifical Mass. No fewer than 36 persons take part in the solemn entry; apart from the celebrant there are six priests in chasuble, seven deacons, seven subdeacons and seven acolytes. The Lyons missal contains a good number of proper sequences, pontifical blessings and prefaces for various feasts. On one day in the year, Holy Thursday, the bishop concelebrates (*i.e.*, celebrates simultaneously) with his priests.

5. The Rite of Braga.—The archdiocese of Braga in the north of Portugal has, in spite of many vicissitudes, preserved its own form of liturgy. It is not, however, an antique rite but dates only from the beginning of the 12th century, when the reforming bishop Gerald (1096–1108) enforced the observance of the Roman liturgy in his see. This new rite, which supplanted the Mozarabic liturgy used until then throughout the entire peninsula, was thus a variant of the Roman rite; apart from such particularities as the preparation of the *oblata* before the offertory and the addition of some proper prayers, it differs from the Roman Mass rite only in points of detail.

6. The Monastic Rites.—Five religious orders, Carthusians, Cistercians, Premonstratensians, Carmelites and Dominicans, preserve their distinctive rites, which, in the case of the Mass, are variants of the Roman rite, sharing many features and reflecting the usage of the period and country (mainly France) in which the orders were founded in the 11th–13th centuries. A certain austerity of expression characterizes the spirit of these rites, in particular that of the Carthusians, which has remained unchanged for centuries; *e.g.*, there is no elevation of the chalice at the consecration.

Comparison of these rites with the Roman Mass reveals the following general characteristics: the prayers at the foot of the altar are much shorter than in the Roman rite; in most of these rites the chalice is prepared before Mass (or during the gradual if it is a high Mass); at the offertory the Host and chalice are offered together; in some of these rites the celebrant is directed to extend his arms in the form of a cross during the canon of the Mass or at the *Unde et memores*. (V. R.)

III. OTHER EASTERN RITES

Space forbids the inclusion here of reference to other than Orthodox Eastern liturgical functions, so those of the lesser Eastern churches are omitted. The Orthodox Eastern Church has never been so rigid in the number of the sacraments as the Latin West, though since the 17th century it has agreed that there are seven; *i.e.*, baptism, chrismation, the Eucharist (described above), penance, anointing of the sick, marriage and holy orders.

1. Baptism and Chrismation.—After a preliminary rite including exorcisms, the candidate's renunciation of the Devil and his profession of faith, baptism proper begins with a litany, followed by the priest's blessing of the water and the oil. He then anoints the candidate on all his members, making the sign of the cross, before immersing him three times in the water with the words "N, the servant of the Lord, is baptized, in the name of the Father, amen, and of the Son, amen, and of the Holy Spirit, amen." After a prayer, the chrismation follows; this is performed on the candidate's members with myrrh previously consecrated by the primate of the national church, together with some of its other bishops. While chrismating, the priest says, "The seal of the gift of the Holy Spirit, amen." Biblical readings end the ceremony.

2. Penance.—Penance takes place in church, but the Orthodox use no confessionals. The penitent confesses his sins in the presence of the priest, who asks God to forgive them. In the Russian church since the 18th century, after a deprecatory prayer offered by the priest, the priest pronounces the absolution in the first person, but in the Greek church the formula is: "May God forgive you through me, a sinner." The priest may also impose a penance and give spiritual advice.

3. Anointing of the Sick.—The sacrament of anointing the sick begins with hymns and a litany, followed by the blessing of the oil and biblical lections. The priest then anoints the sick person, with prayers for his bodily and spiritual recovery. Further lections and prayers follow.

4. Marriage.—The marriage rite begins with a litany and two short prayers, followed by the exchange of rings (betrothal). In the second part of the service (crowning), the marriage proper, there is again a litany, and long prayers asking that this marriage may be blessed as various marriages of the Old Testament were blessed, and the couple preserved as certain Old Testament characters were preserved in danger. Then the priest places crowns above the heads of the couple in the name of the Father and of the Son and of the Holy Spirit, asking God to crown them with glory and honour. Bible readings, a litany, drinking out of a common cup, a procession round a lectern on which lies a Gospel book, hymns and prayers conclude the ceremony. In the case of a second or third marriage (a fourth being forbidden altogether), the betrothal consists of penitentiary prayers, and the crowning is omitted.

5. Holy Orders.—Ordinations take place during the liturgy, but no more than one candidate may be ordained at one liturgy to each grade of the ministry. The subdeacon who is to be made deacon goes three times round the holy table and is then marked three times with the sign of the cross by the bishop, who next commands him to be vested. He then faces the altar and kneels before the bishop, who places his right hand on his head, saying, "The grace of God that fosters the weak and fills up what is lacking chooses N, the reverent subdeacon, to be deacon. Let us therefore pray for him, that the grace of the Holy Spirit may come upon him." The bishop crosses him again three times and prays that God will give him the grace that he gave to Stephen, the first martyr. After a litany has been sung and the bishop has recited another prayer, still keeping his hand over the new deacon's head, the latter is vested with the orarion (stole) over the left shoulder, greeted with the threefold cry of *axios* ("he is worthy") and given the liturgical fan (ripidion). A parallel ceremony is used by the bishop when he ordains a priest, and by three bishops when consecrating a bishop.

6. Other Rites.—Besides the sacraments the *Euchologion* of the Orthodox Church contains many rites of blessing and prayers for various occasions. For the divine office see HOURS, CANONICAL. See also ORTHODOX EASTERN CHURCH; *Worship*.

(A. BL.)

IV. OTHER LATIN RITES

1. Baptism.—In the early church, the principal components of the ritual of baptism were the rite of washing, normally by total immersion, and a profession of faith on the part of the candidate. Hippolytus of Rome, in his *Apostolic Tradition* (c. A.D. 217), gives a detailed description of the ritual of baptism in which this pro-

fession of faith (in the three Persons of the Trinity) formed an essential part of the sacrament. Since about the 8th century the formula of baptism in the Roman rite has lost the character of a dialogue and is simply declarative: "I baptize you in the name of the Father and of the Son and of the Holy Spirit." This formula, which accompanies the pouring of water over the head of the child or adult, is preceded by a series of prayers and exorcisms, a renunciation of Satan and, finally, an anointing with oil of catechumens. The greater part of this preliminary ritual is a survival of the ancient Roman scrutinies, those rites that marked the final stage of the catechumenate and whose object was to weaken Satan's power. When, by the 11th century, it became customary to baptize infants immediately after birth, the exorcisms were annexed to the sacrament itself. For pastoral reasons the Sacred Congregation of Rites in 1962 promulgated a new *ordo* for the baptism of adults in which the ancient ritual of the catechumenate was restored. The conferring of the six preparatory rites of baptism is made to correspond with the various stages of instruction through which the catechumen must pass.

Having been purified in the waters of baptism, the neophyte is anointed with sacred chrism as a symbol of his configuration to *Christos*, God's "Anointed One." Finally, he is given a white garment and a lighted candle, both symbols of the grace he has received, which it will be his duty to preserve until the day of Christ's return.

2. Confirmation.—The Acts of the Apostles (viii, 14-17; xix, 6) indicates the basic rite of this sacrament: it consists essentially in the laying on of hands with prayer. The Roman liturgy has added little to the primitive rite. First the bishop stretches his hands over the candidates while saying a prayer that calls down upon them the seven gifts of the Holy Spirit. Then he deals with each candidate separately, laying his hand on the person's head while, at the same time, anointing the forehead with chrism in the sign of the cross and saying the sacramental formula: "I confirm you with the chrism of salvation, in the name of the Father and of the Son and of the Holy Spirit." Then he gently strikes the cheek of the confirmed person: this latter rite is probably a corruption of the kiss of peace, since it is accompanied by the greeting "Peace be with you." According to the ruling of canon law (canon 788), the conferring of this sacrament should normally be deferred until a child has reached the age of about seven. But the practice, which obtains in some countries, of postponing confirmation until long after the reception of first communion is contrary to liturgical tradition and to the true purpose of this sacrament; for confirmation, being the complement of baptism, is by its nature oriented toward the Eucharist.

3. Penance.—In its ritual and discipline this sacrament has, in the course of the centuries, been subject to considerable development. The chief difference between the modern practice of penance and that of the early Roman church (especially of the 3rd and 4th centuries) is the public character of the latter. The actual revelation of sins (to the bishop or his representative) was always a secret affair; but, according to the older discipline, the penitent made public satisfaction for the sins confessed and was assigned to the rank of penitents. Only at the completion of his penance—usually long and arduous—could he receive sacramental absolution and be restored to communion with the church. The faithful had recourse to this sacrament only for grave and manifest sins.

The practice of private penance seems to have originated in the monastic communities of early medieval Ireland. Already in the 9th century the modern discipline of penance was known and practised: confession of sins to a priest, the imposition of a suitable penance and the conferring of absolution all within a single judicial process. Since about the 16th century the rite of penance takes place inside a confessional where the priest is seated behind a grille. When the penitent has confessed his sins, the confessor offers him such direction of conscience as he deems necessary and imposes an appropriate penance—usually in the form of prayers to be said. He then absolves the penitent in the name of the Holy Trinity.

4. Anointing of the Sick.—Scriptural evidence for the rite of anointing is furnished in the Epistle of St. James (v, 14-16).

There are two major periods in the history of this sacrament: that before and that after A.D. 800. It is clear that in the first period anointing was regarded primarily as a sacrament of the sick. Of the three effects of the sacrament—bodily health, spiritual well-being and forgiveness of sins—the early liturgical texts place bodily health first in order. From about A.D. 800 onward, as the rite of anointing becomes increasingly organized, the practice of reserving the sacrament to those in danger of death is gradually established. The association of anointing with deathbed penance had the consequence that this sacrament was held to be a last pardon accorded by the church to the dying.

According to the present-day ritual of the sacrament, the priest anoints the eyes, ears, nose, mouth, hands and feet of the sick person, using a specially blessed oil (*oleum infirmorum*). While anointing with the sign of the cross the various parts of the body, he utters the formula: "Through this holy anointing and by his most tender mercy may the Lord pardon you for whatever offenses you have committed through . . ." (here the particular sense or member is specified). The three prayers that follow the anointing are urgent petitions for bodily recovery.

5. Holy Orders.—This is the sacrament that confers upon a man an altogether unique participation in Christ's priesthood. It has three degrees: the episcopate, the priesthood and the diaconate. The subdiaconate, although included among the major orders, is not a sacrament; like the minor orders, of which there are four, it was instituted by the church to fulfill a particular liturgical need. The four minor orders, which existed in Rome as early as the 3rd century, are acolyte, exorcist, lector and doorkeeper. Before being eligible for any ordination, it is necessary for the candidate to receive the tonsure, a rite that raises a layman to the status of cleric.

The laying on of hands forms an essential rite in the conferring of the sacrament of holy orders. In episcopal ordination this is performed by the three consecrating bishops; in priestly ordination, by the bishop and the assisting priests; in ordination to the diaconate, by the bishop alone. In this particular rite the Roman liturgy has faithfully preserved the prescriptions of Hippolytus' *Apostolic Tradition*.

In 1947 the Holy See issued the apostolic constitution *Sacramentum ordinis*, which decides what constitutes the matter and form, i.e., the elements necessary for validity, of the sacraments of holy orders. In ordination to the priesthood it is the laying on of hands by the bishop, together with the solemn preface that follows, that constitutes the matter and form. Other rites, such as the clothing with sacred vestments, the anointing of hands, the handing over of the chalice and paten, are all of late origin. They are, nonetheless, expressive symbols of the spiritual powers conferred by the sacrament and, in particular, of the priest's dedication to the service of the altar.

6. Matrimony.—The marriage rite, in its essentials, is one of great simplicity. The sacrament is constituted by an official contract: the mutual exchange of consent of the partners. It is the latter who are the ministers of the sacrament; the priest blesses it. Clandestine marriages are no longer tolerated since the Council of Trent decreed that the marriage must be contracted in the presence of the parish priest and at least two witnesses.

The marriage rite, which varies in details according to the legitimate traditions of each country and diocese, has the following general characteristics: First there is the essential rite of the exchange of consent, which takes the form of a dialogue between the priest and the partners. This is followed by the blessing of the ring, which the man places on the finger of his bride as a sign of lifelong fidelity. The priest then blesses the couple. The nuptial Mass, although in practice frequently omitted, should follow. A special Mass formula is provided for this. At the end of the Lord's Prayer the celebrant blesses the bride, exhorting her to model her life on the example set by the great women of the Old Testament. At the end of Mass, using a shorter formula, he blesses the newly wedded couple, praying that they may see "their children's children even unto the third and fourth generations."

7. Vernacular Rituals.—After the publication of the papal encyclical *Mediator Dei* in 1947, the vernacular was introduced

extensively into the administration of the sacraments (though Latin was retained for the essential form, as well as for the blessings and exorcisms), and many bilingual rituals were printed. These new rituals were compiled at the request of the national hierarchies in order to facilitate the participation of the faithful in the sacramental rites. Some of these national rituals, in particular the German *Collectio rituum* (1950), contain many traditional, national elements that do not figure in the Roman rite itself. At the second session of the second Vatican council (1963), it was decided to replace Latin entirely by the vernacular in the administration of the sacraments.

8. Rites Other Than Sacraments.—The sacraments described above, of which the Eucharist is the centre, are the kernel of the Christian liturgy but do not constitute the whole of it. In addition there are the sacramentals, a name given to the other rites and ceremonies of the church, such as blessings, exorcisms and processions; to these may be added the rites of Christian death and burial and a number of set forms of prayers, such as litanies, for use on various occasions. The Code of Canon Law defines sacramentals as "things or actions by which the church, in a certain imitation of the sacraments, is accustomed to obtain by her own prayer certain effects, chiefly spiritual" (canon 1144).

For the divine office, see HOURS, CANONICAL.

Blessings and Consecrations.—Blessings are of two kinds: constitutive and invocative. Constitutive blessings impart to the recipient (person or object) a certain sacred quality that withdraws it from the sphere of the profane. Invocative blessings do not alter the condition of the recipient: in their administration the minister prays that a particular spiritual or corporal effect be granted.

Constitutive blessings are not easily distinguishable from consecrations. Indeed, before the 12th century the terms *benedicere* and *consecrare* were synonymous. Both effect a certain dedication of the object to divine service. Rites of consecration, however, normally include an anointing with chrism, which invests the action with particular solemnity and indicates a more intense petition on the part of the church. Consecrations and constitutive blessings can be conferred on persons or things. The former include clerical tonsure and minor orders, the blessing of abbots and abbesses, the blessing and consecration of virgins. Things and places blessed and consecrated include churches, altars, altar stones, sacred vessels and vestments, cemeteries and bells; also such common elements as water, salt, oil and ashes.

Consecrations can be validly administered only by bishops, unless priests are given the required faculty by law or by apostolic indult. The blessings contained in the pontifical are reserved to bishops. Some of these, e.g., the blessing of bells, are found also, in a somewhat different form, in the *Ritual*: these latter may be employed by simple priests who possess the required delegation. The priest is the ordinary minister of all the other blessings in the *Ritual*, some of which are reserved to the members of various religious orders.

The *Roman Ritual* (1952) contains 177 blessings, whereas the *Ritual* of Paul V (1614) contained only 29. It was mainly in the 19th century that the number of formulas was increased; the many new blessings that were then composed show the desire of the church to sanctify the inventions of the scientific age. Not all the blessings of the *Ritual* are of equal importance. Some, because of their intimate connection with a particular sacrament, deserve to be considered apart: thus the blessing of sick persons is rightly regarded as an extension of the sacrament of anointing. The blessing of water is particularly important, because the sprinkling with holy water accompanies all the blessings of the *Ritual*. The formula of the *Ritual* defines the effects of this sacramental as purification, bodily and spiritual health and, especially, protection against the attacks of Satan. Certain uses of holy water, e.g., the rite of aspersion before Sunday Mass, symbolically recall the sacrament of baptism.

From the earliest times the church linked its blessings with the Eucharist, the sacrament in which natural products receive their supreme hallowing. The early Roman sacramentaries refer to the blessing of various commodities before the final doxology of the

canon; and even to the present time the blessing of the oil of the sick on Holy Thursday takes place at this point of the Mass. As in the Eucharist the priest consecrates by giving thanks, so in its traditional sense the term *benedicere* implies at once the giving of thanks and the invocation of a divine blessing. This eucharistic motif is clearly revealed in the great traditional blessings of the church, whose very form is that of a Mass preface.

Other Rites and Prayers.—Included among the major sacramentals of the church are the rites of exorcism. An extensive use is made of these in the sacrament of baptism, as well as in many liturgical blessings. In cases of certain diabolical possession, the church makes use of a special formula contained in the *Ritual*, entitled "The rite of exorcizing persons possessed by the demon." The components of this rite, which can be administered only by a priest having express jurisdiction from the local bishop, include prayers, readings from the Gospels, the exorcisms proper (commanding the unclean spirit to depart) and, finally, a series of Psalms expressive of the afflicted person's distress.

The church's attitude to death is well expressed by the prayers and rites surrounding Christian death and burial: it is one of sorrow and compunction on the one hand, and serene hope and confidence, founded on the merits of the Saviour, on the other. Over the dying person is said the *Commendatio animae*, a formula that begins with a litany and continues with prayers that God and the heavenly host may joyfully receive the dying soul. The burial service has several parts. First, the priest goes to the house of the deceased to receive the body, which is then brought in procession to the church. As it is carried into the church, the *Subvenite* is sung: "Come to his (her) assistance, ye saints of God, meet him (her) ye angels of the Lord, receiving his (her) soul, offering it to the sight of the Most High." The most important ceremonies take place inside the church, where the body is placed before the sanctuary with the feet toward the altar. The office of the dead, consisting of matins and lauds, may or may not be celebrated, according to national or diocesan custom. This is followed by the celebration of requiem Mass, which includes the chant of the sequence *Dies irae*. At the conclusion of the Mass, the priest proceeds to the coffin and there performs the ceremony of the absolution, beseeching God to pardon the sins of the deceased. The body is then carried from the church to the chant of the *In paradisum*: "May the angels lead thee into paradise. . . ." At the graveside the canticle of Zacharias (Luke i, 68-79) is sung with its response, "I am the resurrection and the life. . . ." The coffin is then sprinkled with holy water, versicles and prayers follow and in conclusion, the priest blesses the body with the sign of the cross.

The church has always attached importance to processions, a form of prayer that facilitates the participation of the faithful. There are processions for different occasions; e.g., in time of war or famine, to obtain favourable weather. Especially important are those that occur annually and whose purpose is to obtain God's blessing on the fields and the fruits of the earth; these are the greater litanies (April 25) and the lesser litanies or rogation days (occurring on the three days preceding the Ascension). Although several of the great liturgical processions are marked by a penitential character, some, such as those of Palm Sunday and Corpus Christi, have the joyful mood of triumphal marches. During the processions litanies are sung, a form of prayer in which the priest, deacon or chanters intone short petitions to which the congregation makes the responses.

The breviary, missal and *Ritual* contain other forms of prayer such as the priest's preparation for Mass and thanksgiving after Mass, prayers while vesting and prayers before going on a journey. (P. Mu.)

V. PROTESTANT LITURGIES

A. LUTHERAN CHURCH

The Lutheran reformers of the 16th century had a strong sense of unbroken community with the medieval and the primitive church—hence their reluctance to innovate in liturgical practice. The reforms they actually introduced reflect both this sense of linkage with the past and their specific theological concerns in this area: the communication of the Holy Spirit and of "forgiveness of

sins, life and salvation" (Luther's Small Catechism) through the Gospel proclaimed by the church's ministry and through the sacraments; the fundamental role of Christ's incarnation, atonement and exaltation for the faith of the church and of the individual; the identity of faith and worship; and man's obligation to respond sacrificially to every communication of divine grace.

They made a distinction between those elements in worship that the New Testament commanded and those that the church had instituted or that had grown up through custom. What the New Testament neither commanded nor forbade was to them an adiaphoron, an indifferent matter; with reference to such "ecclesiastical rites," the Augsburg Confession (q.v.), the basic Lutheran creed, declared that "those should be kept which can be observed without sin and which contribute to peace and good order in the church" (xv, 17), so long as it is clear that they are not essential and do not assuage God's wrath or earn merit.

Martin Luther devised two experimental adaptations of the medieval Mass—the Latin "Form of the Mass and Communion" (1523) and the vernacular "German Mass" (1526)—which exerted considerable influence on the orders of service.

The normal 16th-century Lutheran Sunday and festal service (with seasonal and regional variations) consisted of introit, *Kyrie*, *Gloria in excelsis*, salutation, collect, Epistle, gradual and Alleluia verse, Gospel, Nicene Creed, sermon, offertory, great intercession, preface, *Sanctus* and *Benedictus qui venit*, words of institution, Our Father, *Pax Domini*, *Agnus Dei*, communion, postcommunion, *Benedicamus*, blessing. The celebrant and his assistant ministers wore the traditional eucharistic vestments, sang the service to the traditional chants and ministered before altars with the traditional ornaments. In the cities, the service was largely in Latin, interspersed with vernacular hymns; in the villages the service was in the vernacular throughout. The distinctive difference between this rite and the pre-Reformation Mass lay in the regular preaching of a sermon; the administration of Holy Communion to lay communicants under the form of both the consecrated Host and the consecrated wine at every Mass (although the actual number of communicants at any service seems to have been relatively small for at least a generation); elimination of all terminology that implied that the Mass is an expiatory sacrifice; discontinuance of private Masses without communicants and of the cult of the reserved sacrament; more extensive use of the vernacular (especially in hymns); and the reduction of the church year to Sundays and the major feasts and seasons commemorating events in the life of Christ, with very few commemorations of individual post-biblical saints.

Baptism was administered to infants in church as soon after birth as possible, though rarely during the service, by immersion or by pouring, with many of the old ceremonies (for example, exorcisms, signing with the cross, procession to the font, giving of the baptismal candle and robe, sponsors); adult baptisms were, in the circumstances, rare. The clergy heard the confessions of penitents individually and pronounced holy absolution privately. Where monastic communities accepted the Reformation, the divine office continued to be said in modified form; in the parishes and in schools, a morning office (based on monastic matins, with elements of lauds and prime) and an evening office (based on monastic vespers, with elements of compline) were not uncommon. The sick and the dying were provided for normally by the Holy Communion celebrated at the bedside; extreme unction disappeared. With the perpetuation of the apostolic succession a political impossibility, ordinators were of necessity local pastors. In a few Lutheran territories confirmation survived in a variety of modifications; the present Lutheran practice of confirming adolescents dates largely from the late 17th century. The *benedictio sacerdotalis* (priestly blessing) of marriages continued.

This situation perpetuated itself in broad outlines for over two centuries. The transition of some Lutheran princes and cities (Anhalt, the Palatinate, Brandenburg, Bremen, for instance) to the Reformed religion led to a variety of compromises, although in some cases it stiffened the determination of the Lutherans to retain their distinctive ceremonies, such as bowing the head at the name of Jesus, chanting the lessons and the prayers, lighted can-

dles, exorcisms at baptism, plainsong and polyphonic music, and the historic vestments. The upheavals of the Thirty Years' War, the political vicissitudes of the Lutheran territories, the individualistic influence of Pietism (q.v.), the pragmatic approach of rationalism and the Enlightenment, and the increasing power throughout the Holy Roman empire of the rulers of Brandenburg-Prussia and their determination to enforce a union of their Lutheran and Reformed subjects contributed to a gradual loss of the Lutheran liturgical heritage. The 19th century saw accompanying the confessional revival a liturgical revival, associated with the names of, among others, Theodor Kliefoth, August Vilmar and Wilhelm Loehe; this revival, which is still moving toward its climax, has resulted in the increasingly general restoration of practices that had survived only locally and in some cases had fallen into complete disuse.

Outside the Holy Roman empire, the Lutheran minority churches in Poland, Slovakia, Hungary and Rumania were in general somewhat more tenacious of their heritage. The Lutheran churches in France and Holland quite early assimilated to a Reformed liturgical pattern. The Lutheran folk churches of Denmark, Norway, Iceland and Greenland retained their episcopal structure (though not the apostolic succession), which made possible greater liturgical continuity. The Lutheran folk church of Sweden has its own liturgical history. Strong political pressures from both the Roman Catholic and the Reformed side evoked the conscious resistance of the Lutheran prelates (who stand in the apostolic succession), clergy and people; on balance, Sweden has been liturgically the most conservative Lutheran country on the European continent.

The situation in the homeland at the time of emigration largely determined developments in the political or ecclesiastical colonies. Thus, Finland, Estonia, Latvia and the 17th- and 18th-century colonies on the Delaware consistently mirrored the Swedish situation. Parallels existed in the case of the Danish colonies (including the Virgin Islands), the German settlements in Russia and the missions that European Lutheran churches and missionary societies established throughout the world.

Communities established by European Lutheran immigrants and refugees in the United States, the Commonwealth of Nations (especially Canada and Australia) and Latin America similarly reflected the liturgical situation in the homeland at the time of departure. Due to geographic and political isolation, the immigrants tended to perpetuate their distinctive practices while gradually accommodating them to one another and adapting them to new conditions.

At first each group tended merely to translate its rite into English with limited adaptation. The 19th-century liturgical revival led in 1888 to the drafting of the intersynodical Common Service, which revived the 16th-century rite in substantially the form described above, plus a preliminary office of preparation. Generally adopted by American Lutherans during the next two generations, it underlies the rites contained in the two service books of which one or the other is used by almost all English-speaking Lutherans, the Lutheran Liturgy (1941) of the Evangelical Lutheran Synodical conference and the Service Book and Hymnal (1958). The latter is noteworthy for its introduction of an Eastern Orthodox type of litany as an alternative to the *Kyrie* and of a eucharistic prayer as an alternative to the consecration of the eucharistic elements merely by the words of institution. The Spanish Lutheran rite is substantially identical with that of the Service Book and Hymnal.

Lutheran liturgical practice still varies widely in detail from parish to parish, and there is still considerable resistance to certain aspects of the liturgical movement in many places. But the trend is toward more frequent celebration and reception of Holy Communion; liturgical preaching; more universal use of the prescribed rites; the restoration of the historic vestments; greater employment of the Old Testament in the service; the revival of private confession and individual absolution in forms appropriate to contemporary needs; better church music; and the expression of the historic meanings of worship in language relevant to the 20th century.

B. PRESBYTERIAN AND REFORMED CHURCHES

Presbyterian and Reformed worship varies in its details but not in spirit from church body to church body and from country to country.

Integral to and dominating the classical Reformed idea of worship is the Word of God contained in the Old and New Testaments. Lessons from both testaments are a prominent part of every service. The psalter also plays a large part, especially in the Scottish tradition, which for more than three centuries has had a fine metrical version of the Psalms set to sturdy tunes. Ideally the sermon is an extension of the Word of God and an exposition of Holy Scripture, the showing forth of Jesus Christ crucified and risen, that he may be worshipped, adored and served.

The Swiss reformers broke more radically with the past than did Luther and his colleagues. Huldreich Zwingli, who espoused a purely symbolic view of Holy Communion, abolished ecclesiastical vestments, the traditional Epistles and Gospels, instrumental music and chant, and private confession and absolution. Whereas the Lutherans had undertaken to reform the medieval Mass, Zwingli did away with it and substituted for it a very simple form of preaching service. From 1525 on, the Lord's Supper was to be celebrated only on the Thursday and Friday before Easter and on Easter itself, for a different group in the congregation each time.

In Geneva, Guillaume Farel helped shape the tradition of that community by observing communion three times a year. Although John Calvin was, if anything, even more insistent upon primitive simplicity than Zwingli, both his eucharistic doctrine and his ideal of eucharistic practice were notably higher. After the Zürich agreement (*Consensus Tigurinus*; 1549) Calvin's eucharistic doctrine became dominant nearly everywhere in the Reformed community; but when he attempted to introduce a weekly (or at least monthly) celebration of communion into Geneva, the town council demurred, and Calvin had to content himself with four communion Sundays a year. This became more or less normative for Reformed worship. The Westminster Directory of Public Worship, approved 1645, called for Holy Communion to be "frequently celebrated," but the injunction seems not to have been obeyed.

The English-speaking Reformed communities in Great Britain derive the basic structure of their worship from the order drafted by Jan Laski, the younger, in 1550 for the Dutch refugees in England.

Traditionally, the emphasis in the Reformed churches is on Sunday—which Reformed divines from the late 16th century on regarded as a divine institution replacing the Old Testament sabbath for Christians—with relatively little concern for an ordered church year or for the great traditional festivals.

Beginning in the last quarter of the 19th century a worship revival stirred the Reformed churches and culminated in an impressive roster of new orders of service that reflect sound liturgical scholarship—among them the Book of Common Order of the Church of Scotland (1940), the Book of Common Worship of the Presbyterian Church in the U.S.A. (1946; in process of revision for the United Presbyterian Church in the U.S.A.), the Geneva Liturgy (1946) and the Liturgy of the Reformed Church in France (1955). (See also COMMON ORDER, BOOK OF.) During this period the number of celebrations of Holy Communion has increased beyond the statutory four occasions; monthly (and here and there even weekly) communion services are not unheard of. Nor is it without significance that the first international and interdenominational liturgical quarterly, *Studia Liturgica*, was begun by a Netherlands Reformed minister, Wiebe Vos, in 1962.

The order of service is still highly flexible. One recommended order in the Book of Common Worship consists of the invitation "Let us worship God," a hymn, a call to worship, an act of adoration, a confession of sins and an assurance of pardon, a portion of the psalter with *Gloria Patri*, two Scripture lessons with a hymn or anthem between them, the Apostles' or Nicene Creed, a hymn or anthem, "prayers of thanksgiving, supplication, intercession and Communion of Saints," the Lord's Prayer, the offering, a prayer of dedication, a hymn, a sermon, a closing hymn and the

blessing. An order for Holy Communion adds the collect for purity and the decalogue or *Kyrie* before the confession; calls for the *Gloria in excelsis*, the *Te Deum* or another canticle after the assurance of pardon; prescribes an Epistle and Gospel, the latter preceded and followed by the traditional acclamations, and, after the offering, the invitation to communion, a hymn, the words of institution as a warrant, the setting apart of the elements, the preface, *Sanctus*, a eucharistic prayer, the Lord's Prayer, the words of institution, *Agnus Dei*, the distribution, a prayer of thanksgiving and the blessing.

C. OTHER PROTESTANT BODIES

Methodism began as a movement within the Anglican Church; and though schism ultimately occurred, John Wesley nonetheless commended to his American followers an abridged version of the Anglican Book of Common Prayer under the name of Sunday Service for the Methodists. The American church's organizing conference adopted it in 1784; and though it never came into general use, its orders for the administration of the Lord's Supper and baptism went over into the Methodist Discipline. The conditions under which early Methodism developed, especially in the United States, demanded simple services and spontaneous worship, consisting of song, prayer, Scripture readings and preaching, to which were added the Lord's Prayer, the doxology and the apostolic blessing. The worship revival that began in the 1920s has had a profound effect upon Methodism. The services of many churches became more formal, more and more clergymen turned to the Book of Common Prayer for inspiration and example; and more stress began to be laid, especially in urban communities, on the aesthetic side of public worship. Holy Communion came to be celebrated more frequently; a monthly service is normal. An energetic though numerically small group of clergymen and laymen who called themselves the Brotherhood (later Order) of St. Luke diligently fostered the liturgical idea from 1946. The Methodist Church's Book of Worship is an important and ambitious document, notably because of the wide variety of public services that it provides.

Complete spontaneity of worship is part of the tradition of large numbers of Christians, including the Baptists; the bodies that prefer the designation "Christian" (the Churches of Christ and the Disciples of Christ), called into being by the 19th-century restoration movement, which had as its ideal a return to 1st-century Christian practice; the Mennonites, who stand in a direct line of descent from the radical "left wing of the Reformation"; and the Holiness and Pentecostal bodies, which grew out of Methodism. In these bodies, too, in varying degrees, closer and more frequent contact with other Christians has raised the question if and to what extent they will allow the worship revival to affect their own services. Some have resolutely resisted any accommodation to what they regard as formalism and a quenching of the Spirit; others have found values in the worship revival that they have gratefully incorporated into their own practice without any sense of having violated cherished convictions. These bodies are generally "gathered" churches with authority vested in the local congregation. Local and regional patterns may be traced both in spontaneous worship and in adopting of features of the worship revival, but generalizations are impossible.

Special interest attaches to the worship of the union churches. The United Church of Canada produced an interesting and thoroughly historical liturgy in 1932. The Church of South India has a liturgy whose basic structure reflects the practice of the uniting denominations, with a considerable number of alternatives in both rite and ceremony from other traditions; thus it provides unity in variety rather than uniformity. The United Church of Christ, whose book of worship was in preparation in the early 1960s, united the traditions of the (German) Reformed Church in the United States, which gave Christendom such distinguished liturgiologists as the Mercersburg movement theologians Philip Schaff and John Williamson Nevins; of the (German) Evangelical (Lutheran) Synod of North America, which preserved the surviving remnants of many Lutheran liturgical practices; of the "Christian" component of the Congregational Christian merger, with its restoration

movement approach; and of Congregationalism, with its wide variety in worship, from the stark simplicity associated with New England meetinghouses to a serious concern with liturgy at its highest levels.

The Moravian Church (Unitas Fratrum), whose history goes back to 1457, combines in its worship liturgical elements and a large measure of freedom in prayer. It produced a distinctive Hymnal and Liturgies in 1924.

The worship of the Society of Friends (Quakers) is wholly unstructured. The participants in the service gather, wait expectantly on God in silence and minister to one another in words of exhortation and uttered prayer under what they regard as the constraining and restraining influence of the Holy Spirit.

LITURGY, JEWISH. The liturgy of the synagogue, as embodied in its Book of Prayer (Heb. *Siddur*), is grounded in one of the liturgical prayers of the Bible, Neh. ix, 5-37, two features of which it adopted: (1) the pattern, namely, praise of God or laudation prior to petition or supplication for one's needs; and (2) the threefold praise of God for having created the world, for having chosen Abraham and his descendants as his particular people, and for having liberated the Israelites of old from servitude in Egypt. Though thus rooted in the Bible, the liturgy of the synagogue, it must be remembered, is the product of postbiblical, or rabbinic, Judaism.

WEEKDAY SERVICES

Corresponding to the time-honoured practice of daily prayer in the morning, afternoon and evening, the Book of Prayer comprises services for these three periods of the day. The weekday morning service is composed of three major units: the recital of the Shema (*q.v.*) with its attendant prayers; the Amidah; and the Torah (Pentateuch, *i.e.*, the first five books of the Bible) service, limited to Mondays and Thursdays.

The recital of the Shema consists in the reading of three selections from the Torah in the order given: Deut. vi, 4-9 and xi, 13-21, and Num. xv, 37-41. The designation "Shema" derives from the opening word of the first verse, Deut. vi, 4: "Hear [Shema], O Israel." The term "the Shema" and the expression "the recital of the Shema" signify "[the reading of] the three given excerpts from the Pentateuch." While the latter are not prayers, they are enclosed within a framework of prayers, essentially of praise.

The name of the second major unit, Amidah, is descriptive of the standing posture of the worshiper (Heb. *amad*, "to stand"). The Amidah is a collection of 19 prayers characterized by a blending of supplication with laudation.

At the core of the third unit, the Torah service, is the reading from a scroll of the Torah which, when not in use, is enshrined in the chest known as the Ark (*q.v.*).

The Shema.—The time for the recital of the Shema was determined by the words in the first two selections, namely, "when you lie down, and when you rise," which suggested evening and morning. The Shema, accordingly, is an integral part of both evening and morning worship. In the latter, two prayers precede the Shema and one follows it; these prayers have their counterparts in the evening service. Though the texts of the evening prayers differ from those in the morning service, the contents of both groups revolve about the tripartite praise of God, in keeping with the precedent of Neh. ix. Furthermore, though originally designed to be prayers of praise exclusively, in the course of time supplications were introduced into both groups. Basically, nevertheless, they remain prayers of laudation, each concluding with the formula of praise: "Praised art thou, O Lord."

The morning and evening recital of the Shema serves three distinct purposes: as a profession of faith; as a symbolic equivalent of devotion to the study of the Torah; and as a declaration of allegiance to the kingship of God and his kingdom. These functions are indicated in the second prayer preceding the Shema of the morning service.

Profession of Faith.—First and foremost, the first verse of the Shema, "Hear, O Israel: The Lord our God is one Lord" (or "... the Lord our God, the Lord is One"), constitutes the worshiper's affirmation of faith, and the words "proclaim thy unity" in the prayer reflect this purpose.

Devotion to Torah Study.—The second purpose is expressed in the following petition: "O put it into our hearts to ... learn and teach ... to do and to fulfil ... all the words of instruction in thy Torah." The italicized words allude to a rabbinic observation that the first selection of the Shema focuses on learning the Torah; the second, on teaching it; and the third, on doing or observing its precepts. Underlying this progression leading to a climax—learning, teaching, doing—is the thought that study of the Torah and the teaching thereof are not a form of intellectual exercise but a regimen of training in character building and ethical behaviour.

More on the second purpose of the Shema is mirrored in the statement "we will meditate on them day and night" (in the second prayer prior to the Shema of the evening service), a statement reminiscent of Josh. i, 8: "You shall meditate on it [the Torah] day and night, that you may be careful to do according to all that is written in it." The rabbis understood this verse as declaring that it is every man's paramount duty to devote night and day to the study of the Torah, to the end that he may order his life in keeping with its teachings. The implementation of this duty, however, interfered with earning a livelihood. Hence, the rabbis resolved the problem by ordaining that, in order to discharge his religious obligation, a person should recite the Shema morning and evening; and this act was to be regarded as though he had read the entire Torah or as if he had toiled in its study day and night. Thus the Shema became a substitute for Torah study, or, to be exact, the minimum requirement for the observance of the precept of Torah study; and as a token of Torah study, it served to keep alive the ideal of learning in the consciousness of every adherent of the faith. Furthermore, by identifying the reading of the Torah selections with Torah study, the liturgy made study an integral part of worship. As a result, study of Torah is a form of worship, on a par with prayers of praise and of supplication.

Allegiance to God the Sovereign.—The third function of the Shema adds a new dimension by envisaging the opening verse as a declaration of allegiance to the kingship or kingdom of God, or to both. When, under Roman domination, the vassal state of Judaea was subject to an emperor who made claims to partial divinity, its spiritual leaders were keenly aware of the danger that emperor worship could undermine monotheism, the central doctrine of Judaism. In protest, therefore, they ordained that twice daily it devolved upon every Jew, while reciting the first verse of the Shema, "to accept or take upon himself the yoke of the kingship and kingdom of God." Continuing to serve as an affirmation of God's sole unity, the verse "Hear, O Israel: The Lord our God is one Lord" began to be viewed also as a declaration of God's

sole sovereignty. And since no mention is made of God as king in the Shema, a response, not derived from the Bible but borrowed from the usage of the Temple of Jerusalem, was to be recited directly after "Hear, O Israel," etc.: "Praised be his name, whose glorious kingdom is for ever and ever."

The emphasis on the concept of submission to the yoke of the kingship and kingdom of God is extended to the prayers accompanying the morning recital of the Shema. The first pre-Shema prayer extols God primarily as creator of the terrestrial world. But an insertion portrays him as creator of the celestial world as well, in which the angels "take upon themselves the yoke of the kingdom of God" by exclaiming: "Holy, holy, holy is the Lord of hosts" (Isa. vi, 3). In an interpolation in the second pre-Shema prayer the worshiper petitions for the return of the exiles to the Holy Land, which, in rabbinic thought, is a precondition for the ultimate establishment of God's kingdom on earth. And the post-Shema prayer recalls how the worshiper's forebears concluded their song of triumph over their Egyptian foes with a proclamation of God's kingship: "The Lord will reign for ever and ever" (Ex. xv, 18).

Similar references to God's kingship and kingdom also occur in the first pre-Shema prayer and in that immediately following the Shema of the evening service.

Variations.—The above paragraphs describe the traditional, or Orthodox, morning and evening recital of the Shema with its attendant prayers. The (Conservative) *Weekday Prayer Book* exhibits no divergencies from this pattern. The (Reform) *Union Prayerbook for Jewish Worship* deletes the second Torah selection of the Shema and retains only a short fragment of the third. Moreover, in its morning service the Reform liturgy eliminates the angelology and the reference to Zion in the first pre-Shema prayer and the supplication for the return of the dispersed to Palestine in the second. Virtually no deviations are discernible in the two pre-Shema prayers of the Reform evening service.

The Amidah.—The Amidah is central to morning, afternoon and evening worship. Rabbinic tradition divides it into three parts: the first, a triad of prayers of praise; the second, a group of 13 prayers of petition; and the third, a triad of prayers of praise of thanksgiving. This tradition is tenable insofar as the tripartite division of the Amidah and the characterization of its 13 intermediate prayers are concerned, but not as regards the nature of the first three and last three prayers.

First and Last Triads.—It has been shown by M. Liber that the opening triad of prayers is independent of the others and, what is more, is as much supplicatory as the intermediate group. The first three prayers constitute a "Messianic drama," in which the worshiper petitions for "the coming of the Messiah, the resurrection of the dead, [and] the establishment of the Kingdom of God" (*Jewish Quarterly Review*, vol. xl, pp. 333-343).

As for the closing triad of prayers, it is, as Liber observes, descriptive of "the final and public acts of the daily Temple worship." The supplicatory nature of the first and third prayers of this group is evident from their current texts, which are petitions for the restoration of the cult of animal sacrifices in the Jerusalem Temple and for peace to Israel. The second prayer is composed in part of an acknowledgment of divine providence and in part of thanksgiving for God's blessings.

In sum, the first group of prayers of the Amidah and most of the third belong, like the middle one, to the category of supplications. At the same time, each of the 19 prayers concludes with the formula of praise: "Praised art thou, O Lord." Hence, all but one of the Amidah prayers are a blend of supplication and laudation, with the former as the dominant element.

Central Section.—The intermediate section of the Amidah is composed of supplications which, like the first, focus on the future, for the aim of the recitation of the Amidah was that the worshiper in his petitions should voice his hopes and aspirations for his people, its land and the Jerusalem Temple, before offering any personal prayer his heart might prompt. The place for private prayer was either after the conclusion of the Amidah or within the framework of specified prayers in it.

The intermediate section of the Amidah is, as it were, a mes-

sian drama in 13 acts. It commences with a prayer for "knowledge, understanding and discernment" which, from the rabbinic point of view, are the three indispensable attributes to make Israel aware of its sins that cause the delay in the inauguration of the golden age. Awareness will lead to repentance, followed by God's pardon. At this stage Israel is ready for redemption. Next, the healing of the sick and physically handicapped and the restoration of Palestine's soil to its pristine state must take place, for these, as the rabbis viewed it, are the prerequisites for the gathering of the dispersed back to their homeland. The return of the scattered ones of Israel will then be followed by the reappearance of judges of integrity and the establishment of the kingdom of God. For the latter will be founded on the principles of justice and righteousness, and the judges will be the human agents to execute the will of the divine king and judge. Two tasks must be accomplished by this ideal world order: the suppression of all subversive forces that delayed its consummation and the vindication of all whose faith in God was ever firm and constant. The final phase in the unfolding of the divine plan will be reached with the rebuilding of Jerusalem, capital of the kingdom, and the restoration of the Davidic dynasty.

Variations.—In the opening triad of prayers of the Amidah the Hebrew text of the Reform liturgy substitutes "redemption" for "redeemer," that is, the messianic era for a personal Messiah. Furthermore, it eliminates the doctrine of the bodily resurrection of the dead, replacing it by the immortality of the soul. The Conservative version, on the other hand, while retaining the traditional Hebrew text, in its English paraphrase alters "who revivest the dead" to "Master over life and death." The Reform prayer book includes only 5 of the 13 prayers in the intermediate section of the Amidah, which remains intact in the Conservative ritual. The five retained by the Reform liturgy admit of personal application, being the prayers for knowledge, repentance, divine forgiveness, healing of the sick and divine receptiveness to prayer. As for the closing triad of prayers, both the Reform and Conservative liturgies expunge the reference to the restoration of the Temple cult of animal sacrifices, the former further deleting the theme of the return of God's presence to Zion. Finally, the Reform version does not confine the prayer for peace to Israel but extends it to all God-fearing people.

Torah Service.—Central to the third principal part of the traditional, or Orthodox, weekday liturgy, the Torah service, are short readings from the Torah scroll during morning worship on Mondays and Thursdays, as well as during the afternoon service on sabbaths. While Conservative practice follows tradition, the *Union Prayerbook* of the Reform congregations prescribes a Torah service on sabbath afternoons and a "Reading from Scripture," from the Torah scroll or the pulpit Bible, on weekdays other than Mondays and Thursdays. One usage, however, is common to Orthodox, Reform and Conservative rituals: the prayers of praise, one preceding and the other following, a reading from the Torah, which extol God as giver of the Torah "of truth" in token of his choice of Israel, in whom he "implanted everlasting life."

SABBATHS, FESTIVALS AND SOLEMN DAYS

Common Liturgical Elements.—The three major units of the weekday liturgy are also basic to worship on sabbaths; on the three festivals of Passover, the Feast of Weeks or Pentecost and the Feast of Booths or Tabernacles; and on the solemn days (in popular parlance: high holy days or high holidays) of New Year and the Day of Atonement. There are differences, however. The prayers accompanying the morning and evening recital of the Shema on sabbaths exhibit several additions and other minor modifications. Particularly striking is the sharp contrast between the weekday and nonweekday Amidahs and the Torah services. The two Amidah categories have only one element in common, namely, the opening and closing triads of prayers. Beyond this, however, the nonweekday Amidahs appear in an entirely different form, having a total of 7 instead of 19 prayers. In lieu of the middle 13 prayers of the weekday liturgy, only 1 prayer constitutes the intermediate section. Moreover, a second Amidah, of

seven prayers, is added to the morning service on sabbaths, festivals and solemn days. It bears the name *Musaf*, which means "Additional Amidah," and is, as specified in its intermediate part, in remembrance of the additional sacrifice offered in the Jerusalem Temple on sabbaths, festivals and solemn days. Following this historical reminiscence, the worshiper petitions for the privilege of actively participating some day in the restored Temple cult of animal sacrifices. The New Year Additional Amidah, unlike the other nonweekday Amidahs, comprises nine instead of seven prayers.

In the Orthodox ritual the Additional Amidahs remain unaltered; the Reform liturgy dispenses with them, viewing them as irrelevant in modern times; while the Conservative position is to preserve them as a historic memory but not as a petition for the restoration of the sacrificial cult.

Readings from the Prophets as well as from the Pentateuch are a characteristic feature of the morning service on sabbaths, festivals and solemn days, as well as of the afternoon service on the Day of Atonement. In Orthodox and Conservative practice the Torah lections during the sabbath morning service are extensive; in the Reform liturgy they are abbreviated. Two more points need to be noted regarding Reform usage: first, a Torah service is indicated in the *Union Prayerbook* in the sabbath evening service; second, the reading supplementing that from the Torah during morning worship on sabbaths, festivals and solemn days is not limited to the Prophets but is extended to include lections from the Hagiographa as well.

What distinguishes the nonweekday Amidahs from the weekday Amidah is the former's intermediate section; and the uniqueness of the nonweekday Torah service inheres in the supplementary reading from the Prophets, accompanied, like a lection from the Torah, by prayers preceding and following it. The key to a comprehension of the nature of the intermediate section of the nonweekday Amidahs and of the final prayer after the reading from the Prophets is the phrase *Mikra Kodesh*, derived from the festival calendar in Lev. xxiii, and rendered in English Bibles by "a holy convocation" or "a sacred gathering" or "a religious assembly." *Mikra Kodesh*, however, admits of two more equally valid significations: (1) "a proclamation of the sanctity [of the day]"; and (2) "a reading from sacred writings." The latter connotation is obviously discernible in the practice of reading from the Torah and the Prophets, while the former underlies the liturgy's conception of the sabbath, festivals and solemn days as occasions whose sacred character is to be proclaimed.

The proclamation is made in the home and in the synagogue. On the eve of the sabbath, the festivals and the New Year the Jew in his home declares the sanctity of the day to his family circle before the meal is served by means of the Kiddush prayer over a goblet of wine (see KIDDUSH AND HABDALAH). And during worship in the synagogue he likewise proclaims the sacred character of those days in conjunction with two of the major units of the liturgy, the intermediate part of the Amidahs (the Hebrew technical term for which, like Kiddush, also signifies "a declaration of the sanctity of the day") and after the conclusion of the reading from the Torah and the Prophets. Common to Kiddush, the intermediate section of the Amidahs and the last of the prayers following the lection from the Prophets are a statement that God gave the particular day to Israel, or bequeathed it as an inheritance, and the eulogy "Praised art thou, O Lord, who hallowest," etc. Reflected in the statement and the eulogy is the thought that the proclamation by the individual of the God-given sacred character of the day is bound to have a hallowing effect upon his life.

Prior to the introduction of the Additional Amidah, morning worship on sabbaths, festivals and solemn days was highlighted by the recital of the Shema with its attendant prayers, the (one) Amidah and the readings from the Torah and the Prophets. After the lesson from the Prophets, therefore, the service came to a close. The Hebrew term for the prophetic reading, *Haftarah* (q.v.), attests to this fact, for it denotes "dismissal [time]"; which is to say, that after the completion of the lection from the Prophets the dismissal of the congregation followed. The

Haftarahs were drawn in the main from the consolatory prophecies in the Major and Minor Prophets, which tended to have an uplifting effect on the mood of the worshiper. And the prayers accompanying the Haftarah were the final prayers of the day's service which, though pronounced by the reader of the prophetic lesson, voiced the sentiments of the congregation as a whole.

What was uppermost in the minds and hearts of attendants at the service as it neared completion? The prayers enclosing the Haftarah provide the answer to this question. In the pre-Haftarah prayer the congregation's attention is directed to the prophets from whose works a lesson is about to be read, as well as to the Torah lection that preceded. Reference to the latter was designed to stress the primacy of the Torah. Since the classical prophets served as God's spokesmen, their utterances were inevitably true. With firm faith, therefore, in the truth of the words spoken by the prophets, the congregation listens to the prophetic selection. The post-Haftarah prayers open with the observation that the prophetic pronouncements contain divine promises. As such they are bound to be fulfilled. In a spirit of perfect trust in God's faithfulness to his promises, the worshiper pleads that God may speedily fulfil those promises the prophets made in his name that pertain to the restoration of Zion-Jerusalem, the advent of the prophet Elijah, precursor of the Messiah, and the assumption by the Davidic dynasty of its messianic role. Whereupon a closing prayer follows, in which praise and thanksgiving are extended to God for the spiritual benefits derived from attendance at the service, namely, the privilege of the worship experience, the enlightenment gained from the Torah lesson, the inspiration drawn from the prophetic reading, and the hallowing influence of the particular festive or solemn day. And interwoven with this closing prayer is the declaration of the sacred character of the day given by God for the purpose of enhancing and ennobling the life of every member of the household of Israel.

The reading of a passage from the Torah and of the Haftarah with their attendant prayers is the prerogative of a boy on the sabbath nearest his 13th birthday, when as a Bar Mitzvah (*q.v.*) he avows his readiness faithfully to discharge the duties and obligations incumbent upon him as an adherent of the Jewish religion. The Bar Mitzvah rite is observed in all Orthodox and Conservative houses of worship as well as in a number of Reform synagogues. The latter, however, employ an abridged version of the post-Haftarah prayers.

Sabbaths.—In the sabbath evening service the recital of the Shema with its attendant prayers is preceded by a section named "Welcoming the Sabbath," which the school of Jewish mystics in Safad (Safed), Palestine, originated in the 16th century. It consists of a number of Psalms and a poem commencing with *Lekha Dodi* ("Come, beloved Israel, to greet the sabbath"). The home ritual of Kiddush over a goblet of wine is likewise part of the synagogue evening service on sabbaths (and on the festivals and New Year). In a prayer of the sabbath morning service, joy in the awaited kingdom of God is said to be in store for those who by their observance of the sabbath experience the spiritual delights (*Heb. oneg*) it yields. This concept inspires the *Oneg Shabbat* gatherings on sabbaths in Orthodox, Reform and Conservative synagogues—gatherings devoted to the discussion of timely topics of religious import and to the singing of Hebrew melodies.

Festivals.—Before the Torah service on the festivals, *Hallel* (*i.e.*, Ps. cxlii–cxviii) is recited, followed by the reading of a biblical book: the Song of Songs during Passover; Ruth during the Feast of Weeks; and Ecclesiastes during the Feast of Booths. Shortly after the Haftarah with its prayers, a memorial service (*Heb. yizkor*), devoted to recalling the souls of the departed, is added during the three festivals. Unique to Passover is its home ritual of the Haggadah, *i.e.*, the narration of the events surrounding the emancipation of ancient Israel from slavery in Egypt. In the synagogue, a prayer for dew (*tal*), symbolic of God's reviving power, is included during Passover, and a prayer for rain (*geshem*), symbol of prosperity, during the Feast of Booths. In Reform and Conservative synagogues, the Feast of Weeks, commemorating the giving of the Torah to Israel on Mt. Sinai, is marked by confirma-

tion exercises for boys and girls. While the Bar Mitzvah rite is for boys at the age of 13, the confirmation service is designed for children of both sexes past that age.

Solemn Days.—Characteristic of the Orthodox and Conservative liturgies of the solemn days of New Year and the Day of Atonement is the vast quantity of religious poetry known as *piyyut*, which is intertwined with the prayers enclosing the Shema and with the Amidahs (*see* HEBREW LITERATURE). The Reform ritual reduces *piyyut* to a minimum, confining it principally to Atonement Day.

A unique element in the New Year liturgy is the prayers in connection with the sounding of the ram's horn (*shofar*), which blend the universalistic and particularistic aspects of Judaism. On the side of the former, the hope is expressed in mankind's ultimate recognition of God as supreme sovereign of the universe. Moreover, New Year is envisioned (1) as the anniversary of the creation of the world, specifically, of the completion of creation or of the beginning of the existence of the world inhabited by man; and (2) as a day of judgment on which, on the basis of his evaluation of their actions and thoughts, God determines the fate of all individuals and all nations. On the particularistic side, the focus is on the revelation on Mt. Sinai to the accompaniment of the *shofar* and on the aspiration for the clarion call of "the great *shofar*" to herald the ingathering of all Jewish exiles to the Holy Land—the precondition for the advent of God's kingdom. The Reform liturgy accords sole prominence to the universalistic component of Judaism by declaring it to be Israel's task, as bearers of the Torah, to proclaim its teachings to all men, so that "all dwellers on earth shall hearken unto the sound of the Shofar, and shall worship as one brotherhood."

The Day of Atonement is ushered in with the threefold rendition of Kol Nidre (*q.v.*) prior to the evening service. Part of the Amidahs of the Day of Atonement is the collective confession of sins and the penitential prayers. A memorial service follows the morning reading of the Torah and Haftarah in the Orthodox and Conservative liturgies, and the afternoon service in the Reform rite. Enclosed within the Additional Amidah are two historical compositions: the order of the service by the high priest in the Jerusalem Temple on the Day of Atonement and the (legendary) account of the Ten Martyrs executed by the Romans during their occupation of Judaea. Also unique to Atonement Day is the *Ne'ilah* or closing service.

Minor Festivals.—Purim and Hanukkah have no independent liturgies. Purim is marked by the reading of the Book of Esther, an insertion in the weekday Amidah stating the basis of its observance, and a Torah service. The eight days of Hanukkah are celebrated in the home by the lighting of candles. Singular to its observance in the synagogue are the recitation of *Hallel*, a Torah service and an insertion in the Amidah furnishing the historical background of the festival (the rededication of the Temple).

Kaddish.—In the course of every synagogue prayer service every day of the year, Kaddish (*q.v.*) is recited. Originally a prayer subsequent to a period of study in the Hebrew classics, it in time was assigned its present place in various parts of the traditional liturgy, and is otherwise also employed as the prayer pronounced by those who mourn the death of loved ones.

(L. J. Lit.)

LITVINOV, MAKSIM MAKSIMOVICH (1876–1951), Soviet diplomat who was commissar for foreign affairs from 1930 to 1939, was born in Bialystok in Poland on July 17, 1876, of Jewish middle-class parents. His real name was Meir Walach. He received a high-school education and early in his life, while serving in the army, became involved in Marxist politics. In 1898 he

CULVER PICTURES, INC.

LITVINOV IN 1942

joined the Russian Social Democratic Workers' party in Kiev. As a result of his revolutionary activities he was arrested in 1901 but escaped and in 1902 fled abroad to Great Britain, where he lived almost continuously until 1918. In 1915 he married Ivy Low, daughter of Sir Sidney Low, a British historian. He joined the Bolshevik faction of the Social Democratic party and took an active part in its work abroad. After the Bolshevik seizure of power in Nov. 1917, Litvinov was appointed diplomatic representative of the Soviet government in London, though that government

had not been recognized by the British. It was later alleged that he had not kept his agreement to refrain from engaging in propaganda activities, and in Oct. 1918 he was arrested. He was released in Jan. 1919 in exchange for the release of Robert Bruce Lockhart and other British subjects resident in Russia. On his return to Russia in 1919 he joined the staff of the commissariat for foreign affairs, of which in 1921 he was made deputy commissar. He remained in this field for the remainder of his active life.

Litvinov represented the Soviet government at the Genoa and Hague conferences, 1922; and between 1927 and 1930 he led the Soviet delegation to the preparatory commission for the Geneva disarmament conference. On July 21, 1930, he was made commissar for foreign affairs. He was the principal Soviet delegate to the League of Nations disarmament conference at Geneva in 1932 and led his country's delegation to the World Economic conference in London in 1933. He won considerable fame for his advocacy at the League of various sweeping plans for disarmament, which he put forward in the name of the Soviet government. He first used the phrase that "peace is indivisible." Among his other achievements was the successful conduct of negotiations for establishing relations between the U.S.S.R. and the U.S. in 1934.

Litvinov was credited with a sincere desire to promote understanding between the U.S.S.R. and the western powers and with a genuine fear of the aggressive intentions of Nazi Germany. In Sept. 1938, when Germany was pressing Czechoslovakia to cede the Sudeten territories, Litvinov declared his country's readiness to give Czechoslovakia effective assistance if France would do the same. It was his opposition to German ambitions, and his Jewish parentage, that accounted for his removal from the post of foreign commissar on May 3, 1939, on the eve of the reorientation of Soviet foreign policy toward collaboration with Germany.

After the German invasion of the U.S.S.R., Litvinov returned to public life, this time as ambassador to the United States (Nov. 6, 1941). He retained this post until Aug. 21, 1943, when he returned to Moscow as deputy commissar for foreign affairs. He continued throughout World War II to play an active, if not a prominent, part in the conduct of Soviet foreign policy, especially as far as relations with the western powers were concerned. He went into retirement on Aug. 25, 1946, and died in Moscow on Dec. 31, 1951. He was accorded a state funeral. (D. Fd.)

LIU CHOU (LIUCHOW), a city in central northern Kwangsi Chuang Autonomous Region, China. Pop. (1958 est.) 190,000. Until 1937 it was called Maping. An important U.S. advance air base was located there during World War II. The city is located 300 mi. northwest of Canton on the Liu Chiang, which drains southeastern Kweichow, and is at the head of year-round junk navigation, and steam launch navigation in the summer. Liu-chou is an important transportation centre for roads and railroad lines

leading north into Hunan, northwest into Kweichow, and south toward Vietnam. Coal is mined, and lumber produced, to the northwest. The city, in the early 1960s, was developing into a regional centre of light industry, with the beginnings of heavy industry, and was growing rapidly in population. (J. E. Sr.)

LIUDOLFING, a German dynasty whose members rose from leadership in the duchy of Saxony during the Carolingian period to reign as German kings from 919 to 1024, thus constituting what is generally known as the Saxon dynasty (see GERMANY: History). The founder of the house was the count Liudolf, who energetically defended Saxony against the Danes and Slavs and who is accorded the title of duke (*dux*) by contemporary chroniclers. On his death (866), Liudolf's political power passed to his sons Bruno (d. 880) and Otto (d. 912). Otto withstood attacks by the Hungarians, extended his authority over Thuringia south of Ostphalia (908) and, after the death of the last Carolingian king (Louis the Child) in 911, assumed the ducal title. Though Otto was now the most powerful prince in Germany, the duke of Franconia was in 911 elected king as Conrad I instead of him; but after Conrad's death (918), Otto's son became German king as Henry I in 919 (see HENRY). Thereafter Henry's descendants Otto I, Otto II, Otto III (*q.v.*) and Henry II were kings successively until 1024. Otto I, however, in 961(?) granted the duchy of Saxony to the margrave Hermann Billung, thus breaking the dynasty's link with its original seat. Otto I's brother Henry was duke of Bavaria (*q.v.*), being succeeded in 955 by his son Henry II the Wrangler (d. 995), father of the German king Henry II. The Liudolfing dukes of Swabia (*q.v.*) were Otto I's son and grandson, Liudolf (d. 957) and Otto (d. 982). (C.-E. P.)

LIUDPRAND (LIUTPRAND, LUITPRAND) (c. 922–c. 972), Italian chronicler, whose works are a major source for the history of Italy and Germany in the 10th century. Of noble Lombard family, he joined King Hugh's retinue as a page; after Hugh's fall (947) he entered the service of King Berengar who sent him on an embassy to Constantinople (949). Having quarreled with Berengar on his return, he found refuge at the court of Otto I, where he rose to a prominent position. Otto made him bishop of Cremona in about 961, and in the following year he was present at Otto's imperial coronation. Having become one of the king's principal diplomatists, he went in 968 on another embassy to Constantinople, to demand the hand of a Greek princess for the future Otto II. He died probably in 972.

A Lombard patriot and enemy of Berengar, Liudprand became a loyal adherent of Otto I; and his writings are coloured by his political enmities and loyalties, as well as by his personal prejudices, as for instance against the Greeks. While his *Antapodosis*, an account of events from 888 to 949, is directed against Berengar and Willa, his *Historia Ottonis* is meant to justify the emperor's ecclesiastical policy; and his *Relatio de legatione Constantinopolitana* may have been intended to serve as political propaganda for the resumption of the war against the Byzantines. But despite their strongly polemical and often biased character, his works are among the most valuable historical sources for the history of Italy and the empire during his time. Liudprand knew Greek and had a considerable knowledge of Roman literature; and his works constitute an important document of contemporary classical learning. The most recent edition of Liudprand's works is by J. Becker, in *Monumenta Germaniae Historica in usum scholarum*, 3rd ed. (1915); Eng. trans. by F. A. Wright (1930).

See W. Wattenbach-R. Holtzmann, *Deutschlands Geschichtsquellen im Mittelalter*. *Deutsche Kaiserzeit*, I, 2 (1948); M. Lintzel, *Studien über Liutprand von Cremona* (1933). (N. R.)

LIU SHAO-CH'I (1898–), president of the People's Republic of China and a leading theoretician of the Chinese Communist Party, was born of poor peasant parents in Ning-hsiang District, Hunan Province, probably in 1898, though some sources give 1905. Liu attended middle school in Ch'ang-sha and studied in Shanghai and at the Peking University. He joined the Communist Party in 1921 and became a labour organizer in Shanghai. In 1921 he was sent to the Far Eastern University in Moscow. The next year he returned as a labour organizer in coal-mining districts along the Kiangsi-Hunan border. In 1927 he was elected to the

central committee of the Communist Party. After a second sojourn in Moscow, he began organizational work in the Kiangsi Soviet and was later commissar of the New Fourth Army. He was elected to the Politburo in 1942 and later served in other high offices. His theoretical essays became standard texts in Communist China. In 1949 Liu was made vice-chairman of the central government council in Peking. On April 27, 1959, he succeeded Mao Tse-tung as chairman (president) of the People's Republic of China.

Late in 1965 a power struggle apparently began to develop in China. On one side were Mao Tse-tung and the head of the army, Lin Piao. Liu and the Communist Party secretary Teng Hsiao-ping appeared to be leaders of the opposition. In an apparent effort to break Liu's power, Mao and Lin in 1966 mobilized bands of young militants called Red Guards and encouraged them to denounce Liu and his allies.

Early in 1967 the supporters of Mao launched a personal attack on Liu. Through the medium of the Chinese Communist press agency and also in the policy journal of the party's Central Committee they denounced Liu's essays as contributing to "bourgeois revisionism." This marked the first official criticism of Liu's writings.

(R. C. N.; X.)

LIVER (HEPAR). The liver is a gland, the largest in the body. It is located in the upper right part of the abdominal cavity. It is rather soft, so that the surrounding organs push in its surface, but as soon as the living liver is taken out of its position, as during surgery, the depressions disappear. Its weight of approximately 1.5 kg. (3.3 lb.) represents about one-fiftieth of the total body weight. The liver has many different functions, each of which is based on its strategic location in the blood stream. It is a filter and clearing station that purifies blood; a storage place for food, particularly for sugar and vitamins; a producer of proteins of various kinds and of antibodies; and a gland that aids in digestion and acts as a remover of waste. All vertebrate animals and only vertebrate animals possess a liver.

Animal liver in man's diet is an important source of protein and fat and vitamins, especially of vitamins A, D, E and vitamin B complex. Because of its high content of iron, copper and particularly of vitamin B₁₂ it is useful in the dietary control of certain kinds of anemia.

Functions.—The liver is a mass of cells through which the stream of venous blood flows as it returns from the intestine to the heart. As the blood passes through the wall of the gut, foodstuffs and occasionally poisonous substances are added

to it. Laden with these materials, the blood passes immediately through the liver, which acts as a filter, removing noxious substances, destroying or inactivating poisons by chemical means and removing bacteria.

The liver also acts as a storehouse, taking nutritional material from the blood and storing it for future use. Among the stored substances is sugar, which is taken from the blood under the influence of the hormone insulin (q.v.), produced in the pancreas. The sugar is converted into storable glycogen, which remains in the liver cells until it is needed for energy production, at which time it is reconverted into sugar under the influence of another pancreatic hormone, glucagon.

Fat, vitamins and other foodstuffs also are stored in the liver cells. Purification and storage are by no means the only functions of the liver. As the blood flows through it, the liver adds to the blood plasma proteins, among which albumin, fibrinogen, globulins, prothrombin and heparin are important. The liver also adds antibodies to the blood, which counteract disease-producing poisons (toxins) produced by bacteria. Thus it is a part of the defense system of the body.

Not only does the liver receive materials from the intestine via the blood stream, but it also is connected with the intestine by a system of tubes through which a stream of bile flows from the liver into the gut. Bile is a green liquid, secreted by the liver, that contains many different substances, among them bile acids, which aid in fat digestion, and bile salts, which help in the absorption of fat and fat soluble substances such as vitamins A, D, K and E. Many red blood cells are destroyed in the bone marrow, spleen and liver. Hemoglobin, which gives these blood cells their red colour, is thus released and flows freely in the blood. The liver picks up this dye and transforms it into bilirubin (a reddish pigment) and biliverdin (a greenish pigment), which flow with the bile into the intestine and are responsible for the brown colour of the feces. Waste products of the body activity, such as urea and uric acid, are excreted by the liver through the bile stream. Cholesterol also is eliminated from the liver through the bile, but most of it is reabsorbed by the intestine and thus is not lost.

Embryological Development.—Developmentally, the liver is the successor of the yolk sac of lower vertebrates. Its development is best exemplified in the amphibians. The female frog produces eggs in her ovaries. In these eggs, a great amount of nutritive material (fat, protein and sugar) called yolk is deposited.

The egg is laid in the water, and an embryo, then a young larva and later a tadpole develop from it. The yolk is activated and put at the disposal of the developing organism. Most of the cells that contain yolk are located in the belly of the embryo, just behind the newly formed heart. Hollow spaces develop in the mass of yolk cells. These spaces enlarge and become connected with each other and with the heart, and blood cells develop in them. Thus, through these primitive blood vessels in the yolk sac, the nourishing substances that are liberated from the stored yolk come into the blood and, by way of the heart, are pumped into all parts of the larva. Meanwhile, the intestine develops. Blood vessels grow from the main artery toward and around the intestine and from there toward the yolk sac. These blood vessels hook up with the network of blood vessels in the yolk sac.

Gradually, the cells in that region are depleted of yolk. At about the time the yolk has been used up, the mouth of the young tadpole opens, and it begins to eat. The food that it eats is digested in the gut, and through the wall of the gut penetrates into the blood vessels connected with the vessels in the former yolk sac. These vessels are surrounded by the cells that formerly contained the yolk. They are now empty and ready to store food again, but they are no longer yolk cells. They have become

FROM ELIAS, "LIVER MORPHOLOGY," BIOL. ABH. 30, CAMBRIDGE UNIVERSITY PRESS (1920).

FIG. 2.—PORTION OF THE LIVER MURALIUM AND LABYRINTH

FROM D. J. CUNNINGHAM, "TEXT-BOOK OF ANATOMY," OXFORD MEDICAL PUBLICATIONS

FIG. 1.—POSTERIOR SURFACE OF THE LIVER

liver cells and can perform all the functions that liver cells must perform.

What were formerly yolk vessels are now called liver sinusoids. The yolk sac has become a liver. Since the liver produces bile, which must flow into the intestine, some liver cells arrange themselves so that they form the wall of a system of tubes, called bile ducts.

The main bile duct into which they all converge is termed the common bile duct. This common bile duct grows until it reaches the intestine and opens into it.

In man the development is quite different. The human embryo develops in the uterus, where it receives nourishment from the blood of the mother, and therefore the human egg contains almost no yolk. However, since man descended from lower vertebrates, the early human embryo has a yolk sac. This yolk sac is empty; yet, as if it were to remind us of our lower vertebrate ancestry, a dense net of blood vessels (the vitelline vessels) develops in its wall. A little later is developed a second system of blood vessels (the umbilical vessels), which brings nourishment from the uterus. The vitelline and umbilical veins join just behind the heart and enter into the heart together. From the fork of their junction a network of blood capillaries grows into a mass of embryonic connective tissue (called septum transversum). This capillary network has an outlet into the heart.

Many cells detach themselves from a ventral outpocketing of the wall of the primitive gut at its anterior junction with the yolk sac. Others detach themselves simultaneously from the lining (mesothelium) of the body cavity. These cells from both sources (entodermal and mesodermal) migrate into the spaces between the vitelline-umbilical capillaries in the septum transversum and surround the capillaries completely. They become liver cells.

Immediately they assume the primary function of liver cells—that is, storage of food that is brought to them from the uterus through the umbilical veins. The bile ducts develop from liver cells and join in the common bile duct, which in turn joins the intestine.

In the chick the liver arises from tubular extensions of the gut wall. Unfortunately this exceptional type of development has become the basis for standard descriptions of liver development in textbooks.

The liver of the embryo has the additional function of producing blood cells, a function that in the adult is carried on by the bone marrow.

Among vertebrate animals, 20 different modes of liver development have been found. But regardless of the method by which the liver develops, the end result is always the same. It is as if several houses were to be built according to the same floor plan and elevations, but with different building materials and methods of construction. At the end, each house is wallpapered inside and covered with stucco externally so that they all look alike, and no one except a construction expert can tell how each house was built.

This observation is contradictory to the biogenetic law of Johannes P. Müller and Ernst Haeckel and to the laws of embryogenesis of Karl Ernst von Baer, which tell us that the embryos of various species are alike, but that the adults differ. Although there is much truth in these "laws," the comparative embryology of the liver shows that they are by no means universal.

The livers of embryos of various species are extremely different, while the livers of adult vertebrates are in essence all alike.

Structure.—G. G. Simpson, in *The Meaning of Evolution*, has explained that if an organ shows great variations in adults from species to species, that organ must be adequate but it cannot be perfect. But if an organ is of equal construction throughout the entire range of its occurrence, then that organ must be perfect. Any divergent construction would be inadequate, and a better construction would be impossible.

How, then, is this perfect liver built that can perform so many different tasks? Its construction is extremely simple, yet almost nothing was known about its microscopic structure prior to 1949

and almost nothing was known about its gross anatomy before 1952. The liver of every vertebrate animal (including man) is a continuous mass of cells tunneled by a maze of connected cylindrical spaces in which a network of specialized blood capillaries is suspended. One should imagine the liver to be a huge building with a maze of crooked hallways and long, narrow, crooked rooms. Neighbouring rooms (the lacunae hepatis) are openly connected with each other, forming a three-dimensional labyrinth (the labyrinthus hepatis). The walls between them are built not of stones but of liver (hepatic) cells. In lower vertebrates these walls (laminae hepatis) are two cells thick, while in songbirds and mammals, including man, they are only one cell thick. Such a system of connected walls is known as a muralium (from *murus*, "stone wall").

The liver of lower vertebrates, since its laminae are two cells thick, is a muralium duplex; that of higher vertebrates is a muralium simplex. The hepatic cells that compose the liver walls are connected, as the electron microscope shows, by little pegs that fit into depressions of neighbouring cells exactly in the manner of snap fasteners.

Between adjacent liver cells are minute tubes, the bile canaliculi, so small that they can rarely be seen in the light microscope. Electron microscopy shows that protoplasmic threads (microvilli) project into the bile canaliculi. The bile canaliculi together form networks of polygonal meshes, each surrounding an individual hepatic cell. Each liver cell possesses one, two or three spherical nuclei, each containing a nucleolus.

The size and number of the nuclei depend on the volume of each individual cell; this volume, in turn, depends on the location of the cell in the muralium. The hepatic cell also contains many mitochondria and piles of double membranes composed chiefly of ribonucleic acid. On the side toward the lacunae, the liver cells are studded with fingerlike and leaflike projections visible only by electron microscopy.

FIG. 3.—PORTA HEPATIS, THROUGH WHICH PORTAL VEIN AND HEPATIC ARTERY ENTER LIVER AND THROUGH WHICH BILE DUCTS LEAVE IT. PORTAL VENOUS BLOOD COMES FROM INTESTINE; HEPATIC ARTERIAL BLOOD COMES FROM THE AORTA. BILE FLOWS THROUGH COMMON BILE DUCT INTO INTESTINE. BLOOD, AFTER PASSING THROUGH THE LIVER, FLOWS THROUGH HEPATIC VEINS AND INFERIOR VENA CAVA BACK INTO THE HEART

FIG. 4.—ELECTRON MICROGRAPH (ABOUT 12,000X) OF HUMAN LIVER, SHOWING AN ERYTHROCYTE (E) OCCUPYING MOST OF THE SINUSOIDAL SPACE (S). FAT GLOBULES IN SINUSOID AND IN KUPFFER CELL (K) (UPPER LEFT) REPRESENT AN ADMINISTERED RETICULOENDOTHELIAL TEST EMULSION. SPHERICAL MITOCHONDRIA (M) AND DARK PARTICLES OF GLYCOGEN (G) ARE SHOWN IN PARENCHYMAL CELLS (RIGHT). AT LOWER CENTRE IS PART OF A FAT-STORAGE CELL OF ITO (FSC)

In the lacunae are suspended specialized capillaries, the successors of the yolk vessels, known as sinusoids. These sinusoids are lined by flat cells, called Kupffer cells after their discoverer, which have the ability to engulf and digest (phagocytize) particles of dirt, worn-out blood cells and bacteria. Until 1957 the Kupffer cells were believed to form an uninterrupted lining of the sinusoids. Electron microscopy, however, shows that there are spaces between them and pores in them through which liquid can pass directly from the blood stream to come into immediate contact with the myriads of submicroscopically small projections of the liver cells that pervade the narrow space (Disse space) between the solid part of the liver cells and the Kupffer cells.

The numerous functions of the liver are all carried out by the Kupffer cells and the hepatic (liver) cells. A great deal is known about their structure, but it appears that the more details are learned, the less is understood about their astonishing variety of function.

Gross Anatomy.—The liver receives its chief blood supply from the intestinal capillaries that converge to form the mesenteric veins. These, together with a vein from the spleen and a few small veins from the stomach, converge into a short but thick vessel called the portal vein. This is so named because it enters the liver at its "door" (porta hepatis). This door is a deep and broad depression in the postero-inferior (dorso-caudal) surface of the liver. The portal vein divides, in the porta hepatis, into a left and a right trunk, from which a number of branches (rami venae portae) arise. These branches were unknown to anatomists in 1952, although Francis Glisson had described them in all detail in 1654, but in 1952 an accident led to their rediscovery.

The liver acts upon the portal venous blood, as noted above. But for all this work, the liver needs energy, which it must derive from the combination of carbon (contained in foodstuffs) with oxygen.

Oxygen is provided by a relatively small artery, the hepatic artery, the smaller branches of which accompany the rami venae portae. The branches of both the portal vein and the hepatic artery empty into the sinusoids.

Blood flows through the sinusoids into tributaries of the hepatic veins. The latter empty into the inferior vena cava, which returns the blood to the right atrium of the heart.

The porta hepatis is not only the entrance door for portal and arterial blood but also the exit for bile. The minute bile canaliculi converge inside the liver into ductules (little tubes), small ducts, large ducts, and then into ducts so thick that they can be seen with the naked eye. These ducts run along the portal vein branches, but the bile in them flows in the direction opposed to that of the blood flow. The bile ducts of ever-increasing calibre finally converge in the porta hepatis into the hepatic duct.

Outside the liver, the hepatic duct divides into two large branches. One of them, the cystic duct, ends in a large sac, the gall bladder. The internal lining of the gall bladder is thrown into many folds whereby its surface is increased. The cells lining it bear many tiny projections (microvilli). The gall bladder serves for short-term storage of bile, and at the same time it takes (through the microvilli) water out of the bile, making the bile more concentrated. If this concentration is carried to excess, gallstones consisting chiefly of cholesterol are formed. The other branch of the hepatic duct is the common bile duct. This duct leads into the upper part of the small intestine, the duodenum. At its exit, the common bile duct is guarded by a ring muscle, the sphincter of Oddi. Some animals, such as the horse, do not possess a gall bladder, a fact showing that the gall bladder is not necessary for life.

LIVERMORE, MARY ASHTON (née RICE) (1820-1905), U.S. feminist and reformer, was born in Boston, Mass., Dec. 19, 1820. She studied at the female seminary at Charlestown, Mass., and taught French and Latin there. She also taught in a plantation school in southern Virginia, and for three years conducted a school of her own in Duxbury, Mass. Upon returning from Virginia she worked vigorously for the abolition of slavery for temperance, and for social reform. With Daniel Parker Livermore (1819-99), Universalist clergyman and editor, whom she married in 1845, she cooperated in liberal enterprises for 50 years.

During the American Civil War, as an associate member of the U.S. Sanitary Commission, she organized many aid societies, served in hospitals and behind battlefields, and contributed to the success of the Northwestern Sanitary Fair in Chicago in 1863.

Convinced by her war experiences that for status and self-expression women required the ballot, she wrote and lectured extensively for 30 years in the United States and Britain, advocating suffrage, education, and remunerative employment for women. In 1869 she founded *The Agitator*, which in 1870 was merged into the *Woman's Journal* (Boston), of which she was an associate editor until 1872. She served as president of the Illinois, the Massachusetts, and the American woman suffrage associations.

Dynamic, eloquent, and devout, she maintained wide acquaintance and correspondence with persons in all walks of life. With Frances E. Willard she produced a biographical directory of American women, and with Elizabeth Cady Stanton and Susan B. Anthony, a history of woman suffrage. Her individual publications comprise articles and several books including *The Children's Army* (1844), *My Story of the War* (1888), and *The Story of My Life* (1897).

Mary Ashton Livermore died at Melrose, Mass., on May 23, 1905. (E.A. C.)

LIVERPOOL, CHARLES JENKINSON, 1ST EARL OF (1727-1808), English statesman, was born at Winchester on April 26, 1727, the eldest son of Col. Charles Jenkinson. He was educated at Charterhouse School and University College, Oxford, and became private secretary to Lord Bute, the favourite of George III, in 1760. Jenkinson was elected member of Parliament for Cockermouth in 1763 and was appointed undersecretary of state

in 1761. Promoted joint secretary of the treasury in 1763, he became leader of the "king's friends" in the commons after the retirement of Bute from active politics.

During the next 20 years he held a series of minor offices: at the admiralty and treasury (1766-73); vice-treasurer for Ireland (1773); master of the mint (1775-78); from 1778 to 1782 he was secretary at war, during the American Revolution. In 1786 he became chancellor of the duchy of Lancaster and president of the reconstituted Board of Trade, and as Baron Hawkesbury entered the House of Lords. An able administrator, he entered the cabinet in 1791 and was created earl of Liverpool in 1796.

Although too ill to attend cabinet meetings after 1801 he retained his cabinet seat and his office at the Board of Trade until May 1804, but resigned the chancellorship of the duchy in November 1803. He died in London on Dec. 17, 1808. (A. AL.)

LIVERPOOL, ROBERT BANKS JENKINSON, 2ND EARL OF (1770-1828), Tory prime minister of England from 1812 to 1827, was born on June 7, 1770, the eldest son of the 1st earl, and was educated at Charterhouse school and Christ Church, Oxford. During his grand tour he witnessed the fall of the Bastille (July 14, 1789), and in 1790 was elected, while still under 21, member of parliament for Lord Lonsdale's borough of Appleby. His early speeches established his reputation and launched him on a long and successful public career, serving under William Pitt the Younger as a commissioner of the India board (1793-96) and master of the mint (1799-1801). As foreign secretary under Henry Addington (afterward Viscount Sidmouth) from 1801 to 1804, he negotiated the peace of Amiens and was in the cabinet with his father. He was created Baron Hawkesbury in 1803, a title he had borne by courtesy since 1796. A misfit at the foreign office, he became home secretary in Pitt's last cabinet (1804-06) but refused the premiership when Pitt died, accepting instead the local wardship of the Cinque Ports. He was again home secretary (1807-09) under the duke of Portland and secretary for war and the colonies (1809-12) under Spencer Perceval. For a politician he was singularly modest and unambitious, knowing his own limitations.

After Perceval's assassination on May 11, 1812, Jenkinson did not accept the premiership in June 1812 until he realized that, without him, the Tory party would break up. He then hoped to discover a brilliant man whom he could train as his successor, saying that he would be very willing to resign in favour of another Pitt.

Liverpool's great administrative experience, ability as a speaker and knowledge of financial matters were outstanding, but it was his remarkable prudence, businesslike habits, tact and discretion which enabled him to perfect himself in the art of keeping together a cabinet and party deeply divided on such fundamental questions as Catholic emancipation, the corn laws, free trade and liberal and nationalist movements abroad. His name tended to fall into obscurity after his death because in the cabinet he was overshadowed by George Canning and to a lesser extent by Lord Castlereagh. In describing him as the "arch mediocrity" Benjamin Disraeli did him less than justice. By restoring the gold standard in 1819 he once more put the currency on a sound basis and during his premiership administrative reform both in church and state made great headway. Unlike Pitt and his successors he refused to buy seats in parliament with the promise of peerages. Liverpool initiated the practice of making all ecclesiastical appointments subject to merit and suitability irrespective of influence: a policy continued and consolidated by Sir Robert Peel in the 1840s. This high-mindedness was the result of his strong evangelicalism. Liverpool died in London on Dec. 4, 1828, having lived in retirement since Feb. 1827 when a paralytic stroke put an end to his political life. Though twice married, the 2nd earl had no children and the earldom and barony passed to his half brother, Charles, who died in 1851.

See C. D. Yonge, *Life and Administration of the 2nd Earl of Liverpool*, 3 vol. (1868); W. R. Brock, *Lord Liverpool and Liberal Toryism, 1820 to 1827* (1941). (A. AL.)

LIVERPOOL, a city and a county and parliamentary borough in Lancashire, Eng., the second largest seaport of Great Britain,

lies 202 mi. N.W. of London by road, on the right bank of the estuary of the Mersey, the centre of the city being about 3 mi. from the open Irish sea. On the north the city is partly bounded by the borough of Bootle, along the shore of which the line of docks is continued. Pop. (1961) 745,750.

The form of the city is that of an irregular semicircle, the base line formed by the docks and quays extending about 9 mi. along the northeastern bank of the estuary, the latter varying in breadth from 1 to 2 mi. The city lies on a continuous slope of sandstone varying in gradient toward the river. The old borough, which lay between the pool (now filled in) and the river, was a medieval pattern of narrow alleys, and during the 16th and 17th centuries it was affected several times by plague. When the town spread up the slopes beyond the pool, conditions improved.

The city is broadly zoned as follows: lying along the river's edge are the docks and quays, together with the ancillary warehousing and other port facilities, as well as a variety of industrial plants closely associated with the import and export of merchandise. The commercial shopping area forms the centre of the semicircle and occupies broadly the site of medieval Liverpool. Round the city centre are the older suburban residential and industrial districts, the nuclei of which are the original outlying villages, which were absorbed by boundary extensions. Beyond these and up to the city boundary are the 20th-century private and municipal residential areas, with generous parks and open spaces. Sefton, Walton Hall and Newsham parks, of 269, 130 and 147 ac., respectively, are but three of the many parks in the city, which has 2,300 ac. of recreation space within its boundary. The Otterspool Riverside promenade by the Mersey is 20 ft. wide and overlooks the Welsh hills. At Aintree, 5 mi. N., is the racecourse where the Grand National is held annually in March.

As a major British port, Liverpool was a target for German aerial bombardment during World War II and sustained considerable damage, not only to commerce and industry but also in its residential areas; 6,500 dwellings were totally destroyed, and more than 125,000 damaged.

History.—During the 8th century, colonies of Norsemen settled on both sides of the Mersey. After the Conquest the site of Liverpool formed part of the fief granted by the Conqueror to Roger de Poitou. Although Liverpool is not named in the Domesday Book, it is believed to have been one of the six berewicks, or subordinate manors, dependent on the manor of West Derby therein mentioned, and cultivated by 53 villeins (peasants), 62 bordars (day labourers), 3 plowmen, 6 herdsman, 1 horseman, 2 bondmen and 3 bondwomen. After various forfeitures and regrants from the crown, it was handed over by Henry II to his falconer Warine. In a deed executed about 1191 by John, earl of Morton (afterward King John), who was then lord of the honour of Lancaster, in which he confirms Henry Fitzwarine in the possession of Liverpool, the name of the town first occurs. Probably its most plausible derivation is from the Norse *Hliðar-pollr*, "the pool of the slopes." Another possible derivation is from the provincial English *lever*, the yellow flag or rush, O.E. *laefer*, any rush-like or sword-bladed plant. (See the *New English Dictionary*, s.v. "Levers.") Yet another derivation could be from the Anglo-Saxon *lither*, meaning "lower," and pool. The grant on which the city's coat of arms is based is the mythical "liver" bird, but in origin this bird was probably the eagle of St. John, King John having granted Liverpool its first charter in 1207.

Besides his honour of Lancaster, Prince John possessed also the lordship of Ireland, and he therefore needed a port where men and supplies could be shipped. Into the tidal waters of the Mersey a small stream ran, forming a pool at its mouth. This pool could provide harbourage for the largest vessels of those days and lay conveniently near to the castle of West Derby. After his accession to the throne, John repurchased the manor from Fitzwarine, giving him other lands in exchange. On Aug. 28, 1207, he issued letters patent granting Liverpool the same status as any other free borough upon the sea and invited his subjects to take up "burgages," or allotments, in the new town, which was built along the brow of the hill on which Castle street and the town hall are erected. The high cross stood near the present town hall, and

there the main line of street was intersected by another line extending from the riverside to the Townsend bridge, which crossed the pool where the end of Dale street now is. Considerable use was made of Liverpool in the 13th century for shipping stores and reinforcements to Ireland and Wales. In 1229 a charter was granted by Henry III confirming in detail that previously granted by his father, making Liverpool a free borough forever, and authorizing the formation of a merchants' guild. Several charters were granted until the reign of William III and Mary II, whose charter was that under which the town was governed until the Municipal Corporations act of 1835. In 1880, when the diocese of Liverpool was created, the borough was transformed into a city by royal charter. In 1888 it became a county borough, and in 1893 the style and dignity of lord mayor was conferred on its chief magistrate. The city council consists of 40 aldermen and 120 councillors.

Liverpool sent two representatives to parliament in 1296 and again in 1307. The next time it sent members was in 1547. From 1588 to 1592 the borough was represented by Francis Bacon. Since 1951 Liverpool has returned nine members to parliament: for Edge Hill, Exchange, Garston, Kirkdale, Scotland, Toxteth Park, Walton-on-the-Hill, Wavertree and West Derby.

Under the Municipal Corporations act of 1835, the boundaries of the original borough were extended, and there were several extensions afterward. In 1932 was added the township of Speke, where the municipal airport was established.

The crown revenues from rents and the royal customs were leased from time to time to the corporation or to private persons. The first lease was from Henry III in 1229, and in the same year the borough, with all its appurtenances, was bestowed with other lands on Ranulf, earl of Chester, from whom it passed to the earl of Derby, who seems to have built Liverpool castle between 1232 and 1237. The lands of his grandson, Robert de Ferrers, were confiscated in 1266 when Liverpool passed to Edmund, earl of Lancaster.

The corporation of Liverpool has possessed from a very early period considerable landed property, the first grant having been made by Thomas, earl of Lancaster, in 1309. This land was originally of value only as a source of turf for firing, but in modern times it has become a profitable building site. A large proportion of the southern district is held in freehold by the corporation and leased to tenants for terms of 75 years, renewable on a fixed scale of fines. Liverpool again became the property of the crown when Henry IV inherited it from his father, John of Gaunt. In 1628 Charles I sold Liverpool to certain merchants of London, who in 1635 reconveyed the crown rights, including the fee-farm rent of £14 6s. 8d., to Sir Richard Molyneux, then Viscount Molyneux of Maryborough, for the sum of £450. In 1672 all these rights and interests were acquired by the corporation and in 1777 converted into a perpetuity. With the growth of commerce these dues increased enormously and became a cause of complaint to those with shipping interests. An act of 1857 transferred the dues to a new body of dock trustees on payment of £1,500,000, largely applied to liquidate the corporation's bonded debt. In 1858 the trustees were constituted as the Mersey Docks and Harbour board.

During the Civil War the town was fortified and garrisoned by parliament. It sustained three sieges and in 1644 fell to Prince Rupert.

Liverpool's trade developed slowly. From £10 per annum at the beginning of the 13th century, the crown revenues had increased toward the end of the 14th century to £38, after which they declined. The Black Death, about 1360, killed a large part of the population. The Wars of the Roses in the 15th century retarded progress for at least a century, during which period the crown revenues were finally leased at £14 6s. 8d., and they continued at this figure until the sale by Charles I. It is, however, not safe to conclude that the reduced fee-farm rent represents an equivalent decline in prosperity; the privileges conferred by the various leases differed widely and may account for much of the apparent discrepancy. The true rise of the commerce of Liverpool dates from the Restoration. Down to that period its population probably never exceeded about 1,000. Its trade was chiefly with Ireland,

France and Spain, exporting fish and wool to the continent and importing wines, iron and other commodities. The rise of the manufacturing industry of south Lancashire and the opening of the American and West Indian trade gave the first impulse to the progress that has continued. By the end of the 17th century the population had increased to 5,000. In 1699 the borough was constituted a parish distinct from Walton. The small existing harbour was found insufficient, and in 1709 Thomas Steers constructed a wet dock with floodgates impounding the water, so as to keep the vessels floating during the recess of the tide.

About that time the Liverpool merchants entered on the slave trade, into which they were led by their connection with the West Indies. In 1700 the "Liverpool Merchant" carried 200 Negroes from Africa to Barbados; in 1730, encouraged by parliament, Liverpool went heartily into the new trade. In 1751, 53 ships sailed from Liverpool for Africa. The ships sailed first to the west coast of Africa, where they shipped the slaves, and thence to the West Indies, where the slaves were sold and the proceeds brought home in cargoes of sugar and rum. By the end of the century five-sixths of the African trade centred on Liverpool. Just before its abolition in 1807, the number of Liverpool ships engaged in slave traffic was 185, carrying 49,213 slaves a year. Another branch of maritime enterprise that attracted the attention of the merchants of Liverpool was privateering, which, during the latter half of the 18th century, was a favourite investment.

The abolition of the slave trade did not bring to Liverpool the ruin that had been prophesied, and trade with the fast-developing North American continent was further increased by the introduction of steam-driven ships in the early 19th century. The reformed town council, after a few years of acute political dissension, displayed a pioneering spirit in the field of public health, encouraged to do so, no doubt, by the problems arising from the mass immigration from Ireland after the famines of the 1840s. Liverpool appointed W. Duncan the first medical officer of health in 1846. As the town became more wealthy, there was increased interest in cultural affairs. In 1849 the Philharmonic hall was opened, and in 1852 Liverpool acquired one of the first public libraries in the country. A museum was provided by Sir William Brown in 1860 (primarily to house the natural history collection left to the citizens of Liverpool by the 13th earl of Derby) and an art gallery (opened in 1877) by Sir Andrew Walker. In 1855 the *Liverpool Daily Post* began publication, and in 1879 the *Liverpool Echo* was started as an evening newspaper.

In the 20th century the opening of the Queensway road tunnel (1934) greatly increased the flow of traffic through Liverpool on a north-south axis and brought the residential and industrial areas of Cheshire and Staffordshire into closer touch with Liverpool and southwest Lancashire. After World War II large blitzed areas in the centre of the city had to be cleared, but it was not until 1952 that the major tasks of central redevelopment could be undertaken. In 1963 a new plan was proposed to rebuild the centre. Large suburban estates had also been developed at Norris Green, Dovecot, Speke, Kirkby, Croxteth, Gateacre and Childwall.

The original supply of water was from wells in the Triassic sandstone. In 1847 an act was passed under which works were constructed and extended later at Rivington, about 25 mi. distant. The vast increase of population led to further requirements, and in 1880 another act gave power to impound the waters of the Vyrnwy, a tributary of the Severn. These works were completed in 1892 and a second pipeline added in 1905. The capacity of the Vyrnwy reservoir is 13,125,000,000 gal. and the catchment area 23,150 ac. in extent. The water from Lake Vyrnwy is conveyed to the city through four main pipelines. In 1957 a new reservoir with a capacity of 16,400,000,000 gal. was authorized at Tryweryn near Bala in north Wales, its water to be fed into the river Dee and drawn off into the Liverpool supply at Huntington, near Chester.

Architectural Features.—Although the city possesses many buildings of considerable architectural merit, the development of the commercial and shopping centre on the site of the medieval town has obliterated practically all traces of the earlier buildings. The town hall, opened in 1754 and designed by John Wood of Bath,

ELSAM, MANN & COOPER LTD.

LIVERPOOL CATHEDRAL ON ST. JAMES'S MOUNT, BEGUN IN 1904

is of particular merit; it is a rectangular building in the Corinthian style, surmounted by a dome that was added after a disastrous fire in 1795. The old Bluecoat hospital (1717), a Queen Anne group built round a courtyard off Church street, is a fine example of its period; the interior suffered considerable damage in World War II but was later rebuilt. Fine examples of 19th-century domestic architecture are to be found in Rodney street and in the Abercromby square area round the university. These dwellings were formerly the residences of Liverpool merchants. Outstanding among many buildings in the Classic Revival style is St. George's hall, designed by Harvey Lonsdale Elmes and completed in 1854. This imposing building, in addition to providing a large public hall, also houses the assize and crown courts and is surrounded by open spaces and gardens sufficiently extensive to enable its splendid classic proportions to be appreciated. After the death of Elmes in 1847, the building was completed by Charles Robert Cockerell, who also designed other important buildings in the city. Adjacent to St. George's hall is the impressive group of buildings in William Brown street, comprising the Technical college, the City museum, the Central library and the Walker Art gallery.

Of the many modern buildings of architectural merit, the most famous are the Anglican and Roman Catholic cathedrals (*see below*) and the three buildings overlooking the river at the pierhead: the Royal Liver building, the Cunard building and the offices of the Mersey Docks and Harbour board. The Philharmonic hall, replacing the old one that had been burned down, was opened in 1939. It is a finely proportioned concert hall with excellent acoustics for orchestral concerts and its own Philharmonic orchestra.

Ecclesiastical Architecture.—Prior to 1699 Liverpool came within the parish of Walton-on-the-Hill, but in that year the chapel of ease of Our Lady and St. Nicholas at the pierhead separated from its parent to become the first parish church. A second church, that of St. Peter, erected by the corporation, was founded and these two, with a number of subsequent churches, served until the increasing population made the establishment of a see of Liverpool imperative. A public subscription was launched, which realized £100,000, and as a result the see was formed in 1880, with the parish church of St. Peter serving as procathedral. The see is comprised of 223 parishes. Warrington is a bishopric suffragan.

The building of the Anglican cathedral on St. James's mount was begun in 1904 when the foundation stone was laid by Edward VII. The architect, Sir Giles Gilbert Scott, has taken full advantage of the excellent site, and the cathedral is the most important 20th-century addition to the city's sky line. The building is designed in the Gothic style and is built of red sandstone with copper

roof. The Lady chapel was consecrated in 1910 and the choir, east transepts and chapter house in 1924. The organ, dedicated in 1926, is one of the largest in the country (5 manuals, 10,925 pipes). The interior height of the cathedral is 116 ft. and the ultimate length 619 ft. The space beneath the massive central tower is the largest unsupported space known in Gothic architecture.

The Roman Catholic archdiocese of Liverpool embraces the old hundreds of West Derby, Leyland and the Isle of Man. It was formed as a bishopric in 1850, raised to an archbishopric in 1911 and embraces 196 parishes. The parish church of St. Nicholas, Copperas hill, serves as procathedral.

The construction of the Roman Catholic cathedral of Christ the King on Mount Pleasant, to the design of Sir Edwin Landseer Lutyens, was begun in 1933. The original designs were substantially modified and the size reduced by more than one-third. In 1956 it was realized that even the modified designs were impracticable, and an entirely new approach was made. A public competition calling for designs for a new cathedral from architects in the commonwealth countries was won by Frederick Gibberd. The new cathedral was being built in the 1960s.

The Arts and Education.—The free library, museum and gallery of arts, established and managed by the city council, was originated in 1852. The Derby museum, containing the natural history collections of Edward Smith, the 13th earl, was presented by his son. The Mayer museum of historical antiquities and art was contributed by Joseph Mayer (1803–86), a Liverpool goldsmith, who presented his collections to the city in 1867. The museum was wholly destroyed during World War II (in 1941), but most of the valuable collections had been removed to safety; the museum was being rebuilt in the early 1960s. Sir Andrew Walker (1824–93) erected in 1877 the art gallery that bears his name; large additions were made in 1884, the cost being again defrayed by Sir Andrew Walker. The permanent collection of paintings includes the William Roscoe collection of old masters and the bequest (1923 and 1927) of James Smith of Blundellsands of 28 pictures by George Frederic Watts, 4 sculptures by Auguste Rodin, many etchings and engravings by Albrecht Dürer, Sir Francis Seymour Haden and James Abbott McNeill Whistler, together with a large number of modern works, British and foreign. The Picton library, with a circular reading room, was built by the corporation and opened in 1879. It includes the Hornby library of fine art books, prints and bindings; the technical library, used by industrialists and scientists; the international library, on the history, language, etc., of foreign countries; the art library; the record office; and the local history department. The Brown library was the first and was erected by Sir William Brown; it was bombed in 1941 and has been rebuilt. A commercial library contains information for merchants and businessmen.

The city has two theatres in addition to the Playhouse repertory theatre, which is the oldest repertory company in the country.

The local education authority maintains primary, secondary, county and special schools, as well as colleges for technology, commerce, art, building, crafts and catering and a nautical catering school. Voluntary schools provided by foundations include Roman Catholic, Church of England, and Hebrew schools.

The University.—University college, Liverpool, founded by the citizens of Liverpool, received its charter of incorporation in 1881. Three years later it was accepted as a member of the federal Victoria university, and at the same time the Royal Infirmary Medical school, which had been established since 1844, became a member of the college. By 1900 there was a staff of 25 professors and 60 lecturers, and a student body of nearly 600. On the dissolution of the Victoria university, a royal charter, granted in 1903, established the University of Liverpool. Degrees in engineering were instituted and, later, degrees in architecture; in 1904 the New Veterinary college of Edinburgh was transferred to Liverpool, and a chair of veterinary medicine and surgery was founded. After World War I, development was rapid. Between 1920 and 1939 many new buildings and extensions were constructed, including the Jane Herdman Memorial Geology laboratories (1929), the Leverhulme building of the school of architecture (1933), an extension

to the students' union (1935), the Harold Cohen library (1938) and Derby hall, a hall of residence for men students (1938). In 1942 a veterinary field station was opened at Willaston, Wirral, thus continuing the development of a science with which the university has always been prominently associated.

The extension of university education since World War II has brought an increase in staff, students and accommodation; new halls of residence have been built and the old halls extended. The number of chairs in the university is 59, and the faculties are those of arts (responsible for degrees in commerce, architecture and civic design, as well as for degrees in arts); science, including a department of oceanography with the only chair in oceanography in the commonwealth, which works in close conjunction with the marine biological station maintained at Port Erin (Isle of Man) and with the Liverpool Observatory and Tidal institute; medicine, including the school of dental surgery; law; engineering; and veterinary science. The Liverpool School of Tropical Medicine, though separately incorporated, is governed by a committee representative of the university and the merchants and shipowners of Liverpool; and its students take the university postgraduate diploma in tropical medicine and hygiene. Many departments of the university have been entirely rebuilt since World War II.

In 1948 a plan for the development of the university was published, and the city council reserved a site in its own redevelopment plan for the purpose, with Abercromby square as its approximate centre. The university's jubilee was celebrated in May 1953.

Docks, Railways and Roads.—The docks of the port of Liverpool on both sides of the Mersey are owned and managed by the Mersey Docks and Harbour board (constituted in 1858). On the Liverpool side they extend along the estuary $6\frac{1}{2}$ mi., of which $1\frac{1}{2}$ mi. is in the borough of Bootle. The Garston docks, six miles above Liverpool, are also within the city boundary. The Birkenhead docks have not such a frontage but extend a long way inland. The water area of the Liverpool docks and basins is 460 ac., with a lineal quayage of nearly 28 mi. Birkenhead docks contain a water area of about $181\frac{1}{2}$ ac., with a lineal quayage of $9\frac{1}{2}$ mi. The

system of enclosed docks was begun by the corporation in 1709. The Gladstone docks, opened in 1927, are among the best equipped in the world. The sill is 20 ft. below datum level, the entrance is 130 ft. wide and the area with branch docks is nearly 54 ac. A fine graving dock is part of the system. Down to 1843 the docks were confined to the Liverpool side of the Mersey. In 1843 a plan for docks in Birkenhead was carried through, proved unsuccessful, and was acquired in 1855 by Liverpool. The Birkenhead docks were for many years only partially used but are now an important centre for corn milling, the importation of cattle and export trade to the east.

The first portion of the great landing stage, known as the George's Landing stage, was constructed in 1847. This was 500 ft. long. In 1857 the Prince's Landing stage, 1,000 ft. long, was built 500 ft. to the north of the George's stage. In 1874 the intervening space was filled up and the George's stage reconstructed, but it was destroyed by fire and had to be reconstructed a second time. In 1896 it was extended farther north, and its length is now 2,534 ft. and its breadth 80 ft. It is supported on floating iron pontoons (about 200) connected with the river wall by ten bridges, besides a floating bridge for heavy traffic 550 ft. in length and 35 ft. in width. The southern half is devoted to the traffic of the Mersey ferries, of which there are three—New Brighton, Seacombe and Birkenhead. The northern half is used by ocean-going steamers and their tenders. The warehouses for storing produce form a prominent feature in the commercial part of the city. In addition to general produce warehouses, grain warehouses have been constructed by the dock board at Liverpool and Birkenhead, with machinery for discharging, elevating, distributing, drying and delivering. Warehouses for the storage of tobacco and wool have also been built. The Stanley tobacco warehouse is the largest of its kind in the world, the area of its 14 floors being about 36 ac.

The dock board was the first harbour authority to introduce wireless telegraphy as a guide to shipping (1911), and in 1940 the first port radar station was built to serve as a navigational aid to shipping using the Mersey. The Waterloo river entrance

lock was opened in 1949, and in 1962 the Canada-Langton river entrance was reconstructed. The whole of the North docks in Liverpool are now accessible to vessels at all stages of the tide. The new Tranmere oil jetty provides for the discharge of large tankers.

There are four terminal passenger stations in Liverpool. They are: Lime street, Exchange, Central and Riverside stations. Connection with Birkenhead is effected by the old Mersey tunnel (opened 1886) and by the Queensway road tunnel opened in 1934. (See **BIRKENHEAD**.) In 1895 the Riverside station at the Prince's dock was completed by the Mersey Docks and Harbour board, giving direct access from the landing stage to the railway system.

Plans to reorientate traffic in the central area of the city were approved in 1963. These included a new inner motorway to relieve congestion in the city itself and a second Mersey tunnel to alleviate the pressure on the existing one.

Trade and Commerce.—The port is the traditional centre of business life in Liverpool and the adjoining districts that go to

BRITISH INFORMATION SERVICES

A PORTION OF THE DOCK AREA AT LIVERPOOL, THE SECOND LARGEST SEAPORT OF GREAT BRITAIN

make up Merseyside. It is second only to London among British "general" ports, with extensive passenger interests to add to its handling of materials and goods of virtually every type. The total tonnage of these in an average year is of the order of 23,000,000, carried in about 32,000 seagoing vessels.

The commerce of Liverpool, channeled through its port, has a main emphasis on North and South America, western Africa, the Mediterranean countries, the Indian subcontinent and Australasia—a very large proportion of the trading world. The main imports are of raw materials and commodities (in excess of 14,000,000 tons in the mid-1960s, including bulk oil) for use or manufacture in and round Liverpool or in the upcountry areas of industry that it serves. From these areas, principally of Lancashire, the Midlands and west Yorkshire, come in return the chief exports of Liverpool—iron and steel, machinery and manufactured goods of all types from the heaviest products to pottery, textiles and fine goods, compiling a list as long as the concerns of British overseas trade. The export tonnage exceeds 4,000,000.

The port is the hub of the wheel of Merseyside, and in that hub are the ships, the building and fitting of ships, and the manning, victualing and servicing of ships that are known throughout the world. Packed round that hub are major facilities of banking and insurance, of warehousing and of every branch of commercial life, and industries to process imported materials are located as close as possible to the quays. Merseyside has the largest flour-milling centre in Europe, its sugar and oil refineries are well known, oil-seed crushing is a substantial industry and biscuit (cookie), confectionery, rubber and soap factories, somewhat farther from the main port area but well within local boundaries, are also important.

In the late 1920s this picture, with some modifications, would have represented the sum of Liverpool's commerce and industry. But the trade recession that paralyzed the world then had a particularly serious effect on Liverpool, dependent as it was on a maximum passage of the world's goods and, at the worst of the recession, more than 100,000 of Liverpool's citizens were unemployed. To ensure against a repetition of this, by spreading the risk over as wide and productive a field as possible, the Liverpool City corporation took special statutory powers (in 1936), which have since been imitated by many other authorities, both central and municipal—powers to bring work to the worker by means of special facilities, of finance, siting and construction, made available to manufacturing industry. The corporation's industrial estates at Speke, Kirkby and Aintree cover a total acreage of 2,741, and each is on a principal approach to the city from its inland areas of chief contact. The effect, when allied to the efforts of the state since World War II and of private enterprise throughout, has been to add a third partner, manufacture, to the older and better-known interests of Liverpool's life. There are now large factories for electrical and electronic apparatus, diesel engines, jet engines, tires and heavy chemicals. Other products include antibiotics, clocks, scientific instruments, pharmaceuticals and matches. The social process involved of converting a measurable part of a dockside population, accustomed for many generations to casual labour, into an industrial population, working regularly, has been both interesting and successful.

As a result, Merseyside's working population has an infinitely greater industrial element than its grandfathers would have believed possible. The port and all to do with it remains the largest employer of that labour, followed by light engineering, chemicals and pharmaceuticals, food and foodstuffs, the services of commerce and inland transport and a very large number of smaller activities, each substantial in itself and completing the composition of an area that has at least taken definite steps in the direction of economic balance.

Short History (1960); P. Burford (ed.), *A Guide to Merseyside* (1961). (T. Ar.)

LIVERWORTS, small, chiefly prostrate nonvascular plants, constitute two classes of the Bryophyta (q.v.), to which also belong the mosses. The liverworts differ from the mosses principally in the structure of the spore-bearing plants (sporophytes), described below. All mosses are leafy, but some of the liverworts lack leaves or, if leafy, are usually flatter than the majority of

mosses. The leafless forms may be ribbonlike or otherwise flattened and ruffled, but most liverworts have leaflike appendages on the stems.

None of the liverworts has any important economic significance, although some (*Marchantia* and *Conocephaleum*) long ago were thought to have medicinal value for liver ailments in accordance with the doctrine of signatures. In nature these plants play a role as pioneers on newly exposed substrata in the reducing of rocks and woody materials to soil, in retarding soil erosion and in providing both food and homes for small animals.

The liverworts may be divided into the classes Hepaticae and Anthocerotae.

Hepaticae.—Sometimes called the true liverworts or hepatics, these plants may be divided into the leafy and the thalloid forms, the latter being flattened ribbons or rosettes without leaflike structures on the stems. The thalli vary in size from one-sixteenth to one inch in width.

The best-known thalloid species is *Marchantia polymorpha*, which appears like a green fork-like ribbon approximately one-half

FIG. 2.—MARCHANTIA GAMETOPHYTES: (A) ARCHEGONIA BORNE ON LOWER SIDES OF FINGERLIKE RAYS OF STAR-SHAPED STRUCTURE OF FEMALE PLANT; (B) ANTHERIDIA PRODUCED IN CAVITIES IN UPPER SURFACE OF DISC ON MALE PLANT

FIG. 3.—GAMETOPHYTES OF RICCIOCARPUS NATANS FLOATING ON WATER (ABOUT ACTUAL SIZE)

inch in width. It has an upper and lower epidermis with scales along the middle of the latter. The portion between the upper and lower epidermis is filled with walled cavities, each with an opening through a fixed pore in the upper epidermis. The cavities have short, green, cactoid filaments scattered in them.

These thalloid plants are haploid; *i.e.*, are gametophytes with a single set of chromosomes. They are unisexual, and eventually stalklike branches are formed. If female, the sexual branch somewhat resembles a palm tree or an umbrella without its fabric. The female sex organs (archegonia) are hung beneath the rays. The male branches terminate in a flattened, scalloped, screwhead-like structure with male sex organs (antheridia) buried in small-mouthed cavities in the upper surface. At maturity the male cells (sperms) may swim from the ruptured antheridia to the female plants and thence to the female cell (egg) contained in the enlarged, basal portion (venter) of the archegonium.

The fertilized egg (zygote, formed by union of sperm and egg) by apical growth matures into a spore-bearing plant which is diploid; *i.e.*, a sporophyte with a double set of chromosomes. It consists of a foot embedded basally in the venter, a stalk (seta) that attaches the foot to the spheroidal spore-bearing capsule (sporangium), all of which develops within the archegonium. At maturity the cells of the seta rapidly elongate, bursting the archegonium and exposing the capsule. The spores, covered by a compact wall of one or two layers of cells, are often mixed with slender, hygroscopic cells (elaters) that may effect spore dispersal when the capsule splits open or ruptures as a result of wall deterioration. The spore germinates on moist substrata and, after a short (three or four cells) threadlike phase, grows into the ribbonlike gametophyte.

The leafy members of the Hepaticae often resemble mosses but usually can be recognized by the presence of only two rows of leaves (also characteristic, however, of the moss genus, *Fissidens*) or two rows of large leaves and a third row of small leaves on the side of the stem toward the substrate. They vary from species microscopic in size to those in which single leaves may be easily seen without a lens.

In *Trichocolea*, *Ptilidium* and others, the leaves are subdivided into hairlike segments. In *Frullania* and *Jubula* they have a small, pouchlike lobe bent up behind the main portion of the leaf. Some leaves have entire margins; others have long, marginal teeth. Some are smooth; others are rough with pimpelelike projections (papillae).

The sexual life cycle of the leafy species is not essentially different from that of the thalloid forms. The antheridia are borne in the axils of leaves; the archegonia are usually terminal. The sporophyte usually has a longer seta than many of those in the thalloid species.

In addition to reproduction by sexual means, liverworts also produce vegetative reproductive bodies (gemmae) of various shapes and sizes. Some are formed on the surface or edges of the leaves or thalli; others are borne in specialized structures in the form of cups or flasks. New plants are also formed by growth from fragments and by branching and subsequent death of the older portion.

Anthocerotae.—These, often called horned liverworts or hornworts, do not constitute a very large group. American genera include *Anthoceros*, *Phaeoceros* and *Notothylos*. They differ from the hepatics in a number of characteristics, the most important of which is the indeterminate basal growth of the needle-shaped sporophyte. Thus arises the unique situation in which mature spores may be falling from the top of the apically split sporophyte while new ones are being initiated at the base. Also, there is no seta and the foot is large and irregular.

The cells of the hornwort sporophyte have two large chloroplasts containing starch-producing bodies called pyrenoids; cells of the hepatics have several to many small chloroplasts without pyrenoids. The sporophyte has a sterile central column (columnella) and pores (stomata) in the epidermis; these structures are not present in the hepatics. The latter have unicellular elaters, if present; the hornworts usually have irregular multicellular elaters.

The gametophyte is not leafy but a thallus that has cavities, often opening by slits through the lower surface, containing symbiotic colonies of the blue-green alga *Nostoc*. The cells of the gametophyte each have a single, large chloroplast. The sex organs (antheridia and archegonia) are somewhat similar to those of the hepatics but are sunk in the upper surface of the gametophyte, the antheridia occurring in cavities and the archegonia appearing as an integral part of the thallus. The sexual life cycle is similar to that of the hepatics except for the different shape of certain structures as described above. Vegetative reproduction may occur through natural division of the thallus.

The Anthocerotae are interesting for several reasons. The large pyrenoid-containing chloroplasts appear primitive; in contrast, the basal indeterminate growth of the sporophyte makes it appear related to more advanced plants. They are the lowest plants in the plant kingdom to exhibit stomata. These structures, plus the indeterminate growth of the sporophytes, have led some botanists

to suggest that they represent a type ancestral to the ferns. However, in spite of certain primitive characters they are probably the most highly evolved of the liverworts and represent the current end of a line rather than an ancestral form. The symbiotic relationship between the alga *Nostoc* and the thalli of the Anthocerotae suggests that the host may receive nitrogen-containing compounds or other beneficial materials from the alga.

The Anthocerotae are usually found in the moist, dim woodlands of tropical and warm temperate regions. In North America they are occasionally collected in southern Canada.

LIVERY COMPANIES, institutions peculiar to the City of London, are survivals from the medieval trade and craft guilds once universal in Europe. Their name, popularly accepted but not found in their charters of incorporation, is derived from the grant by the court of aldermen of a "livery," or grade of membership in the guild privileged to wear a distinctive clothing in the form of a fur-trimmed gown. Thus the Parish Clerks and the Watermen & Lightermen, though both guilds of ancient foundation, have never been granted a livery and so are not properly included among the livery companies.

There were, in the mid-1600s, 84 livery companies containing 14,000 liverymen, and the numbers were increasing. Most of the companies were incorporated by royal charter between the 14th and the 17th centuries, but the Weavers gained a charter as early as the 12th century, and the Master Mariners, the Solicitors, the Farmers and the Air Pilots & Air Navigators have come into existence since 1925. The incorporation in 1960 of the Tobacco Pipe Makers & Tobacco Blenders is a revival of a former company

which fell into desuetude in the 19th century. The companies vary a great deal in detail and the range of their wealth and influence is wide. Nearly every one of the 84 companies once controlled the craft or trade indicated by its name; 60 were concerned with skilled crafts such as the Goldsmiths, the Carpenters and the Glovers, while 12 dealt with victualing trades, as for example, the Bakers and the Vintners. Most of the companies have now lost control over their trades but the Fishmongers still possess wide and effective powers of search and inspection in Billingsgate fish market, the Goldsmiths continue to "hallmark" gold and silver, and the Gunmakers still "proof" small arms.

Most of the companies are governed by a small self-appointing body known as a court of assistants presided over by a master (or prime warden) and wardens. Few of the companies restrict their membership to persons following the particular calling represented by the company's name, but the Apothecaries' society confines its senior membership to medical men, the Brewers' company is limited to the brewing trade and the Solicitors, Master Mariners and Air Pilots admit only persons qualified in those specialties. By the custom of London, admission to the basic grade of membership of a company—known as the freedom of the company—is by patrimony, servitude (apprenticeship to a freeman of the company) or redemption (purchase). An order of precedence was settled by the court of aldermen in Henry VIII's reign and the first "twelve great" companies are the Mercers, Grocers, Drapers, Fishmongers, Goldsmiths, Skinners, Merchant Taylors, Haberdashers, Salters, Ironmongers, Vintners and Clothworkers.

Origin and Growth.—Though most originated in the early religious fraternities, trade and craft guilds were formally established in the 12th century and in the 13th steadily grew in strength and influence (see GUILD). By the 14th century they had become the predominant power in the governing councils of the City of London and the liverymen still elect the lord mayor and the sheriffs.

The early charters of incorporation granted by Edward III to the Goldsmiths, Skinners, Drapers and a few others were the exception rather than the rule, but Henry VI extended the privilege of incorporation to the four great victualing trades and five leading manufacturing crafts.

It is a mistake to think of these guilds as associations of poor working men, or as the forerunners of the modern trade unions. In the early days apprenticeship was the normal method of entry into a trade or craft and on completion of his indentures and production of his "masterpiece" the apprentice became a freeman of his company and a master craftsman. He might then continue to work as a journeyman for others but would look forward to setting up on his own and taking apprentices in his turn. It was only when he became established that he would aspire to promotion to the livery. Thus the general pattern of the more influential companies was that of a master and court consisting of the leading members, who were often rich merchants; the main body of well-to-do shopkeepers forming the livery; and a substratum of working craftsmen, the freemen of the company.

At the zenith of their power the guilds controlled their members by the exercise of powers conferred by charter or ordinances: to regulate apprenticeship and conditions of employment, to examine workmanship and destroy defective goods, and to enforce rules by fines and penalties. The ultimate sanction was that only those free of the City of London could ply their trade, and the freedom of the city was obtainable only through membership of a guild.

Changing economic and political conditions from the 16th century onward resulted in a gradual but steady loss of power and influence. Repeated attempts to adapt the constitution and powers of the medieval guild to the new pattern of society failed; friction began to develop between the governing bodies of the livery companies and the growing ranks of artisans who resented the restrictions inherent in the apprenticeship system. By about 1787 most of the companies finally abandoned any pretense of controlling their respective trades. However, at the close of the 19th century there was a widespread movement on the part of the livery companies to revive interest in their respective crafts and trades and to devote corporate funds, where these existed, to technical educa-

FIG. 8.—*ANTHOCEROS LAEVIS*, A HORNWORT

tion and charity. Benevolence and the relief of distress were always a principal concern of the old guilds and the livery companies of today continue this tradition.

Modern Activities.—After the middle of the 15th century the practice grew for testators to appoint companies as trustees; for instance, John Colet appointed the Mercers to administer a trust for St. Paul's school (founded 1509). Later in the same century the Skinners company were appointed trustees for Tonbridge school. Other schools maintained by livery companies are Oundle by the Grocers, Aldenham by the Brewers, Gresham's Holt by the Fishmongers, the Aske's schools by the Haberdashers and the Merchant Taylors' school. In the sphere of technical education and the promotion of industrial research the City and Guilds of London institute was founded by the corporation of London and the livery companies in 1880. The Clothworkers built and equipped the department of textiles and colour dyeing at Yorkshire college (now Leeds university) and expended vast sums on numerous technical schools dealing with textiles. The Drapers spent more than £500,000 on their foundation, Queen Mary college (now a principal school of the University of London). The Goldsmiths founded and maintained Goldsmiths' college which they presented to the University of London as a technical institute in 1904. The Salters founded an Institute of Industrial Chemistry which awards fellowships in chemistry and allied sciences. The Skinners have aided the Leather Trades' school at Bethnal Green and have given generously to such institutions as the People's palace, Mile End, the Borough Polytechnic and the Northampton College of Advanced Technology at Clerkenwell. The Carpenters founded and maintain their own Building Crafts Training school. The Leather-sellers' Technical college, built by that company in 1909, is now the National Leathersellers' college. The Cordwainers have their technical college at Hackney; the Tylers & Bricklayers, Joiners, Painter-Stainers, Plaisterers and Wheelwrights are all concerned with technical education in their own particular spheres; and many of the livery companies provide scholarships at schools and universities.

Livery Halls.—The Merchant Taylors and the Goldsmiths are the only crafts known positively to have possessed halls before 1400, though 26 others were built in the next 100 years. Many of the wealthier companies, like the Grocers, the Drapers and the Leathersellers, began by taking over the mansions of feudal magnates or the buildings of a religious community. The Great Fire of 1666 is believed to have swept away as many as 44 livery company halls and some of the less affluent companies were never able to rebuild. In 1939 there were 34 livery halls standing but in the air raids of World War II 16 were destroyed and 14 damaged. By the mid-1960s rebuilding had raised the number to 28.

LIVESTOCK FEEDS: see FEEDS, ANIMAL.

LIVESTOCK JUDGING is an art requiring the ability to select animals, on the basis of outward appearance, or phenotype (see HEREDITY: *Heredity of Quantitative Characters*), and for those characteristics associated with excellent productive performance. It attempts to correlate the appearance factors which will result in the reproduction of meat animals (beef cattle, sheep and swine) which will produce carcasses of high quality with a large proportion of edible cuts. It attempts to select dairy cows for milk production and horses for draft work or performance under the saddle or in harness. Although not a true science, it has served well throughout the world as a tool for livestock breeders to improve their herds and flocks (see ANIMAL BREEDING).

Increased emphasis is being placed in modern livestock judging of meat animals on rate of gain, feed efficiency and carcass quality, items that can be measured accurately, and eventually the grand champion or first prize animal will have to excel in both live appearance and carcass quality. Many times the best steer,

lamb or hog on foot has not been the best in the carcass. Breeding animals (bulls, cows, rams, ewes, boars and sows) will be judged by rate of gain, feed efficiency, reproductive efficiency, milk production (dairy cows) and performance of progeny as well as on live appearance. Livestock judging will then become a combination of an art, based upon eye selection, and a science, based on performance records.

Whenever any characteristic of livestock ceases to be of productive value, it ceases to have a major place in livestock selection. Many times too much emphasis is placed on some minor fancy of a breeder, such as shade of hair colour; and thus the livestock breeder or judge loses sight of the fundamental basis for selection. Although many of these nonproductive characteristics have their place in contributing to the style and beauty of an animal, they should never be emphasized to the degree of masking the real purpose of livestock production; i.e., the provision of meat, milk and wool. The accompanying sample judging card for beef cattle indicates the main points considered in livestock judging.

Certain characteristics should be developed for proficiency in judging livestock:

1. The desire to know livestock. An intrinsic interest in livestock and the desire to know their characteristics, habits and productive points are necessary in a good judge. Livestock judging requires the sacrifice of time and energy for the sake of studying and working with good livestock. A good judge or animal breeder must be livestock minded and be keenly aware of the perplexing problems that confront the breeder who is continuously selecting and culling to improve his livestock quality and performance. The imperfections as well as the perfections of the different breeds, classes and types of livestock must be recognized. Livestock judging and selection must become a real and living task rather than a means of attempting to correctly place a class or group of animals in the show ring or on a farm or ranch.

2. A mental image of ideal types. If only one animal is judged or appraised, it must be compared with some standard, namely the ideal of its kind. If two or more animals are judged, each animal must be compared with the ideal, and then with the others in the class. These ideal types can be learned by observing good individuals in both the live and picture form. Ideal types of livestock have been set up by a majority of the breed associations.

Beef Judging Card

Points to Consider	Placing			
	1st	2d	3d	4th
I. General appearance: straight top-line, deep, broad, uniform in width, low-set, compact, symmetrical stylish, standing squarely, trim middle				
II. Form:				
1. Head—muzzle broad, nostrils large, eyes large and clear; face short, clean and slightly dished; forehead broad; ears medium size and fine texture; horns medium size and well shaped				
2. Neck—thick, short, blending smoothly into shoulders; throat clean				
3. Shoulder—smooth, well-covered with flesh, compact on top; shoulder vein smooth and full				
4. Breast—wide, full; brisket neat and trim with little dewlap				
5. Forelegs—short, strong; arm full, shank medium fine				
6. Chest—deep, wide, girth large, crops full				
7. Back—wide, straight and thickly covered				
8. Loin—wide, straight and deep fleshed				
9. Ribs—well sprung and smoothly covered with firm flesh				
10. Flanks—full and low				
11. Hooks—neatly laid in and smoothly covered				
12. Rump—long, wide, even; level and free from patchiness				
13. Thighs—deep, broad, wide and full				
14. Twist—full and deep				
15. Legs—straight, strong; shanks medium fine				
III. Finish: deep, mellow, firm covering especially over back, ribs and loin; freedom from patchiness and rolls desired. (Finish is of great importance in fat classes, but is not so important in breeding classes as long as the ability to take on finish is indicated)				
IV. Quality: smooth in frame and finish; hair fine, soft; hide mellow; bone medium-size and clean				
V. Dressing percentage: well finished, not paunchy, medium weight hide. (Not considered in judging breeding cattle)				
VI. Breed and sex character: (Applies only to breeding classes)				

ABERNATHY PHOTO CO

JUDGING BEEF CATTLE AT THE 1966 INTERNATIONAL LIVESTOCK EXPOSITION, CHICAGO

Pictures are at best a poor substitute for the same type of live animals, but in cases where only common classes are available, pictures of other classes may be used to advantage. A judge must be constantly in contact with good animals and observe them keenly. Great value can be obtained from intelligently observing good representatives of the various breeds at leading livestock shows, sales, farms, and ranches in all parts of the world.

3. Keen power of observation. The ability to detect important differences in livestock quickly and accurately must be developed. This keen power of observation is the result of intense concentration on the outstandingly good and bad points of an animal. Persistent practice in evaluating livestock in terms of an ideal is a sure way to develop a keen sense of differences. A herdsman knows his livestock well. As with human beings, each animal possesses a physical individuality which sets it apart. These individual differences become apparent to the herdsman through keen observation and habitual contact. The judge, too, must be among livestock and think about livestock to develop his power of observation.

4. Ability to make a logical analysis. Since judging is an art based on observation, it is impossible to appraise animals in the terms of exact percentages. While all parts of an animal do not have the same economic value, each part is interrelated and dependent on the other parts, and in the last analysis, the animal must be considered as a whole. A score card is excellent for learning the parts of the animal if the supposed numerical value of the parts is disregarded. To be sure, the relative importance of various parts on the basis of anatomy and wholesale cuts should be mastered, but to assign definite percentage values to each part of an animal often leads to confusion. Judging is not a mathematical formula or an aggregation of percentages, but is an art requiring practice and sound judgment. A judge must be honest and open minded in his search for facts. In market animals one must be able to appraise commercial values and still recognize the desirable balance in development that the breeders and producers prefer, even though some points such as constitution, feeding qualities, soundness and breed type may not much concern the packer. When one allows bias or prejudice to place a class of livestock, he is catering to his emotions and is disqualifying himself as a competent judge. If one observes the animals accurately, weighs the facts in a balanced manner, never follows

hunches and concludes with a logical placing, his mistakes will be reduced to a minimum. Judging is applied, sound reasoning.

5. Independence of thought. Only in proportion to the extent that a judge exercises independence of thought is he able to improve his judging ability. A judge must be open minded to just criticism from others and make his mistakes steppingstones instead of stumbling blocks, strengthening his ability to select animals correctly.

6. The ability to give effective reasons. This ability depends partly on natural talent but primarily on acquired knowledge and practice. Accuracy is of prime importance. Presenting a pleasant-sounding and persuasive set of reasons without a high percentage of accuracy is worthless. A judge should give the reasons for his placing in a simple, straightforward manner and in terminology that serves to make his reasons clear, logical and to the point. (W. M. B.)

LIVIA DRUSILLA (58 B.C.—A.D. 29), wife of the Roman emperor Augustus and after his death called Julia Augusta, was daughter of M. Livius Drusus Claudianus, a Claudius adopted by M. Livius Drusus (q.v.), the tribune of 91 B.C. She married her cousin Tiberius Claudius Nero, who fought against Octavian (later Augustus) in the War of Perusia (41). To him she bore in 42 a son Tiberius (later emperor), but she was still pregnant with her second son Nero Claudius Drusus (q.v.) when early in 38 Octavian compelled her to divorce Nero and marry him, he having recently divorced his wife Scribonia. The new marriage was childless, but Livia was reputedly a devoted and an influential wife, accompanying Augustus on various journeys and counseling him successfully on state affairs. In her efforts to secure the succession for Tiberius she was credited with bringing about the deaths of many rivals, for instance Augustus' nephew Marcellus in 23 B.C. and his grandsons Lucius and Gaius in A.D. 2 and 4; it was even believed that she hastened Augustus' own end because she feared the reinstatement of his banished grandson Agrippa Postumus. Nothing in these stories is really credible, but the power and ambition of Livia are beyond doubt. To Tiberius after his accession they proved embarrassing: he forbade her to accept certain honours and eventually refused to carry out the terms of her will. In 42 she received divine honours from her grandson Claudius I.

Surviving portraiture confirms the literary tradition of Livia's dignified beauty; she was also noted for her chastity and affability. Her villa at Prima Porta has revealed some excellent examples of Roman painting, now in the Museo Nazionale at Rome.

LIVINGSTON, EDWARD (1764–1836), U.S. lawyer, legislator and statesman, is perhaps best remembered for his work in codifying the law, especially criminal law and procedure. He was born in Columbia county, N.Y., on May 28, 1764. He graduated from the College of New Jersey (now Princeton) in 1781, was admitted to the bar in 1785, and began to practise law in New York city. He was a Republican representative in congress, 1795–1801, where he was one of the leaders of the opposition to Jay's treaty, taking the ground that congress was not bound to appropriate money to carry out a treaty obligation. In 1801 Livingston was appointed U.S. district attorney for the state of New York and

while retaining that office was in August of the same year elected mayor of New York city. When, in 1803, the city was overtaken by an epidemic of yellow fever, Livingston helped to prevent the spread of the disease and relieve distress, and was himself attacked by the fever.

On his recovery he found himself indebted to the government for public funds which had been lost through the dishonesty of a confidential clerk, and for which he was responsible as district attorney. He at once surrendered all his property, resigned his two offices in 1803, and moved early in 1804 to Louisiana. He soon acquired a large law practice in New Orleans and by 1826 had managed to repay the government in full, including the interest.

In Louisiana, he was appointed by the legislature to prepare a provisional code of judicial procedure, which (in the form of an act passed in April 1805) was continued in force from 1805-25. During the war with England from 1812-15 Livingston was active in rousing the mixed population of New Orleans to resistance, and acted as adviser and volunteer aide-de-camp to Gen. Andrew Jackson. In 1821, by appointment of the legislature, of which he had become a member the preceding year, Livingston began the preparation of a new code of criminal law and procedure, afterward known in Europe and America as the "Livingston Code." Completed in 1824, it was accidentally burned and had to be written again. It was presented to the legislature in 1825 but was not adopted. It was at once reprinted in England, France and Germany, and studied all over the world, attaining wide influence. In referring to this code, Sir Henry Maine spoke of Livingston as "the first legal genius of modern times" (*Cambridge Essays*, 1856). His code of reform and prison discipline was adopted by Guatemala. In 1821 he was appointed with Moreau Lislet to revise the civil code of Louisiana, which was substantially ratified.

Livingston was again a representative in congress during 1823-29 and a senator in 1829-31. In 1828 he presented to the senate a system of penal laws for the United States but no action was taken on it. He served for two years (1831-33) as secretary of state under President Jackson. In this last position he was one of the most trusted advisers of the president, for whom he prepared a number of state papers, the most important being the famous anti-nullification proclamation of Dec. 1832. From 1833 to 1835 Livingston was minister plenipotentiary to France at a time when relations between the two countries were strained over claims of U.S. citizens for damages resulting from the Napoleonic Wars. He died May 23, 1836, at his home, "Montgomery Place," Dutchess county, N.Y.

His works include: *Reports of the Plan of the Penal Code* (1822); *System of Penal Law for the State of Louisiana* (1826); *System of Penal Laws for the United States of America* (1828); *Complete Works of Edward Livingston on Criminal Jurisprudence* (1873).

See W. B. Hatcher, *Edward Livingston* (1940).

LIVINGSTON, ROBERT R. (1746-1813), first chancellor of the state of New York, member of the continental congresses and U.S. minister to France, was born in New York city on Nov. 27, 1746. His father, Robert R. Livingston (1718-75), was a justice of the New York supreme court after 1763; his brother Edward achieved distinction in both law and politics. After graduating from King's college (now Columbia university) in 1765, Livingston studied law and was admitted to the bar in 1770. During the American Revolution he served in the second continental congress from 1775 to 1776, again from 1779 to 1781, and in the congress under the Articles of Confederation from 1784 to 1785. He was a member of the committee that drafted the Declaration of Independence, although before signing it he left the congress to take his seat in the newly elected New York convention. He was a member of the committee that drafted the first constitution for the state of New York in 1776. In 1777 he became the first chancellor of the state, a post he held until 1801, and he is best known in history as Chancellor Livingston. With inauguration of the government under the Articles of Confederation in 1781 Livingston became the first secretary of foreign affairs. In this position he approved the peace treaty negotiations

by the American commissioners in Paris but reprimanded them for negotiating without the full concurrence of France. On April 30, 1789, in his capacity as chancellor of New York, he administered the oath of office to George Washington at his inauguration as president in New York city.

As a member of the New York convention of 1788, Livingston had advocated ratification of the new federal constitution, but he later became an anti-Federalist and unsuccessfully opposed John Jay in the New York gubernatorial campaign of 1798. In 1801 Pres. Thomas Jefferson appointed him minister to France where in 1803, in association with James Monroe, he purchased from France the territory then known as Louisiana. (See LOUISIANA PURCHASE.) Long interested in steam navigation, he obtained from the state of New York in 1798 a monopoly of steam navigation on the waters of the state and assisted in the experiments of his brother-in-law, John Stevens. While in Paris he met Robert Fulton and with him in 1802 made successful trials of a paddle-wheel steamboat on the Seine river. In 1803 Livingston and Fulton received a renewal of the steamboat monopoly in New York. Their first successful steam vessel, which operated on the Hudson in 1807, was named after Livingston's home "Clermont." Livingston died at Clermont, N.Y., on Feb. 26, 1813.

See M. L. Bonham, Jr., "Robert Livingston" in S. F. Bemis (ed.), *The American Secretaries of State and Their Diplomacy*, vol. i (1927), (R. B. Ms.)

LIVINGSTON, WILLIAM (1723-1790), U.S. political leader and first governor of the state of New Jersey, was born at Albany, N.Y., on Nov. 30, 1723. He was the son of Philip Livingston (1686-1749), and grandson of Robert Livingston (1654-1728), an important figure in the early history of New York state.

William Livingston graduated from Yale college in 1741, studied law in New York city, was admitted to the bar in 1748, and served in the New York legislature (1759-60). His chief political influence was exerted, however, through pamphlets and newspaper articles appearing in his short-lived *Independent Reflector* (1752-53) and in the "Watch Tower" section (1754-55) of the *New York Mercury*. Together with William Smith (1728-93), the New York historian, Livingston prepared a digest of the laws of New York for the period 1691-1756, published in two volumes (1752 and 1762).

Moving to Elizabeth, N.J., in 1772, he represented New Jersey in the first (1774) and second (1775-76) continental congresses, but left Philadelphia in June 1776 to take command of the New Jersey troops. He was chosen in 1778 to be the first governor of the state of New Jersey and was regularly re-elected until his death on July 25, 1790. Livingston was a delegate to the federal Constitutional Convention of 1787, where he supported the New Jersey or small state plan. The following year he led his state to an early ratification of the constitution.

His brother, PHILIP LIVINGSTON (1716-1778), was a member of the First Continental Congress from 1774 until his death and a signer of the Declaration of Independence.

William's son (HENRY) BROCKHOLST LIVINGSTON (1757-1823) was an officer in the American Revolution and an associate justice of the U.S. supreme court (1806-23). (Ar. S.; X.)

LIVINGSTONE, DAVID (1813-1873), was the greatest explorer-missionary in Africa of the 19th century. He was responsible not only for opening up the southern half of that continent but also for disclosing to the civilized world what he called "the running sore of Africa," the slave trade, as practised in the interior.

Born at Blantyre in Lanarkshire, Scot., on March 19, 1813, the second son of humble parents, Neil and Agnes Livingstone, he went to work in a cotton mill at the age of ten. Even at that early age his energy and powers of concentration showed themselves so that, largely self-taught, he was able, by the time he was 22, to study Greek, theology and medicine at college courses in Glasgow. As a result he took a medical degree in 1840, having been accepted earlier by the London Missionary society as a candidate for the mission field.

Posted by the society to their mission at Kuruman in southern

Africa, he landed in 1841 at Algoa bay. He at once showed the two qualities which made him the great traveler-missionary he soon became, the ability to cope with all the practical difficulties of journeys by ox-wagon, horse or on foot, and a quick understanding of and sympathy with the native African. He was in fact so competent in these things after his ten weeks' journey to his base that after a few weeks there he pushed on with his wagon for another 200 mi., farther than any missionaries had yet penetrated, to seek a place for a mission where none had been before. His next step was to go alone to establish it, so as to learn the native language and explore the possibility of training native teachers.

At this stage Livingstone was plainly the devoted missionary, dedicated to his task of spreading the gospel. He differed from his colleagues in desiring to push far afield instead of wishing to remain in some degree of comfort at Kuruman, and he was already very forceful in his attitude to the Boers whom he regarded as thwarting the work of the missionaries. In following out this independent policy he spent the next seven years building missions, learning the languages and becoming a master at all the skills required for life in such remote places. It was at one of his early mission stations that he was wounded by a lion; he recovered, but at the cost of losing most of the power in his left arm. While convalescing at Kuruman he courted and married Mary Moffat, daughter of the veteran missionary, a step which he admits he took partly in pursuance of his duty as a missionary, though in fact it was also a love match. In the course of his travels he made friends with several sportsmen-hunters, including William Oswell, whose character sorted well with his own and whose wealth was to be the means of a new phase in his missionary career.

Livingstone was intensely interested in what lay ahead of him in what he always called the "dark interior," and by questioning he learned of a mysterious Lake Ngami to the northwest and, more to his purpose, of the powerful and enlightened chief of the Makololo tribe, named Sebituane, still farther north, under whom he hoped to establish a mission station beyond the range of both the Boers and the militant tribe of the Matabele.

With both these objectives in their minds, Livingstone and Oswell made a journey in 1849 across the difficult tract of the Kalahari and reached Lake Ngami and the swamps of the great Okavango river. The presence of tsetse fly and the obstruction of a local chief prevented their going on to Makololo territory. The next year he tried again, taking his wife and small children with him, as he was afraid they might be molested by the Boers, but the party got malaria at Lake Ngami. The next year he was successful when, with his family and Oswell, he followed a new route and found Sebituane on the Chobe river. The friendship between these two remarkable men, the great missionary traveler and the strong and wise black dictator, is the best example of how thoroughly Livingstone understood the African, for though it lasted only three weeks before Sebituane died of pneumonia, yet it was to colour the next four years of his wanderings. It was there that Livingstone first came into direct contact with the slave trade and where he first formed the opinion that the only way to fight it was to undercut it as an industry by bringing trade from the coast by cheaper means. It was at this stage that his missionary fervour became diluted by the more practical need to combat the iniquities of slavery. He felt that he was the man to explore Africa for trade routes and that became his principal aim thereafter.

The decision meant that his duty as a husband and father must take second place to his duty as a reformer and explorer, and reluctantly he decided to send his wife and family home to England and continue alone with his efforts to undercut slavery. Much criticism has been leveled at him for this action but never then or later did he allow his marriage to come before his avowed dedication to his mission and exploration. He returned alone in 1853 to Sesheke, the headquarters on the Zambezi of Sebituane's successor, his nephew Sekeletu, a weaker chief but one who befriended him and helped him to carry out his journeys.

In Nov. 1853 he started on his famous journey through unknown country to the west coast of Africa with 27 men lent by Sekeletu. He still hoped to find a site farther up the Zambezi healthy enough

for a mission station but without success, and he himself began to have severe bouts of fever—no fewer than 27 before he reached the coast, after six months of hardship and danger from hostile tribes. He kept a very full diary and his surveying produced a map which for parts of the route was the only trustworthy one until well into the 20th century.

There is nothing that shows the character of this remarkable man so well as his decision on arriving at Loanda. Reaching his goal as a very sick man, broken in health though triumphant in success, he was at once invited by the captains of ships, including three British men-of-war, to take passage back to England, to health, to his family, to honours. It hardly occurred to him to accept, even when closely pressed. He had brought his men to a place whence they could not return by themselves, therefore he must take them back again. What seemed to him common humanity showed to the world as a degree of Christianity and a deep sense of brotherhood with the African which has rarely been equaled. He took his party on the even longer and more perilous journey back to Sesheke and was surprised to find his return welcomed almost as a miracle. For himself there was the disappointment that the route he had followed would not serve his great purpose of trade to undercut slavery: he now had to find a route to the east coast of the continent.

Sekeletu gladly furnished him with the means of following down the Zambezi to the sea, supplying over 100 of his tribesmen, and he started eastward in Nov. 1855. Only 50 mi. on his journey he discovered the great falls (Victoria falls), of which he had heard, and took this wonder feature of Africa as a disappointment rather than as a reward of exploration, since it was a barrier to the navigation he hoped to find practicable down the river. Half of the journey was through quiet unknown country, but by comparison with the Loanda route it was straightforward, and on arrival at the coast he was given hospitality by the Portuguese, before finding a ship to take him to England, leaving his Makololo in apparently good hands until he could return to lead them back again. In England he was received with honours and acclaim, forced into a limelight which he disliked and obliged to give lectures, which was a burden to him for he had always been a poor speaker. During the year of his stay in England he wrote his book, *Missionary Travels*, one of the classics of explorer narratives, not without literary merit.

Before leaving Africa he had received a letter from the directors of the London Missionary society which in polite language made it clear that they did not approve of the apparent diversion of his efforts from settled missions to exploration. It was a great shock to him, since he felt himself just as sincere a missionary as ever, but he accepted a severance from the society after 16 years of service.

His fame was to be the undoing of his plans. He had purposed to go back, alone, to take his Makololo back to their tribe, hoping to do it by water up the Zambezi and complete a survey for a trade route. Instead he found himself appointed as a peripatetic consul to the Zambezi region and in command of an official expedition under the aegis of the foreign office. He was given carte blanche for the arrangements and to a less extent for the selection of the personnel, and this exposed a weakness which neither he nor anyone else had ever expected. He had proved himself a master at commanding and organizing Africans, never suspecting that he could prove a failure at managing white colleagues and a large expedition. His greatest mistake was in taking his younger brother Charles, whose temperament was entirely unsuited to an expedition, as, in lieu of any other office, "moral agent."

Sailing from England in March 1858 there began an expedition which lasted for six years of disharmony and frustration, though, strangely enough, it had far more important consequences than his former explorations. He found that there were myriad obstacles to the navigation of the Zambezi, but, to balance that, he discovered Lake Nyasa and a feasible route to the interior. He took many of his Makololo back to their tribe as he had promised and came back, largely by canoe, down parts of the great river. He explored more of Portuguese East Africa than any one had thought possible, yet in doing so he opened a way for the slave trade. He

saw the commencement of the Universities mission to Nyasaland only to witness disaster and retreat come upon it. Only one of his team, John Kirk, came out of the venture with full credit, second only to his leader in fortitude and singleness of purpose.

Livingstone's own exertions were as incredible as ever but marred by his inability to command, and his persistence in clinging to the cause of most of the bickering, his own brother. A crowning sorrow to him was the loss of his wife who had, at his instance, come to join him and died of fever on the banks of the lower Zambezi. When he was recalled by the foreign office in 1864 he was a disappointed man and his narrative, written in collaboration with his brother, is a poor record of the failures intermingled with successes.

After a comparatively quiet year in England writing his book, Livingstone was persuaded without difficulty by his influential friend, Sir Roderick Murchison, to go back to Africa with the dual purpose of finding out more about the slave traffic in the interior and discovering the sources of the great rivers Zambezi, Congo and Nile. This time he was once more to be the only white man, commanding a curious mixture of Indians, mission boys and local carriers, 60 in number, together with animal transport. They landed at the mouth of the Rovuma river in April 1866 intending to pass round Lake Nyasa far from the influence of the Portuguese, with whom he was no longer *persona grata*. But the skill of the master traveler had gone and in five months he had lost by desertion or treachery all but 11 of his men.

Once past Lake Nyasa he was in unknown territory and back to his old practice of observing everything, mapping and even taking daily records of rainfall, temperature and barometric pressure, a model of scientific exploration. He was often a prey to his old enemy, dysentery, and for the second time in his life, lost his chest of medicine, again by robbery. His situation was now desperate. Reduced to a party of nine men he could not turn back and he was forced to seek help from the Arab traders, who were kind to him mainly because they dared not let him return to the coast to tell the tale of their misdeeds. So for the next four years there was the strange paradox of the great opponent of the slave trade associating with those who lived by it, and being dependent on them. During that period he discovered the southern end of Lake Tanganyika, and Lakes Mweru and Bangweulu.

The ardent missionary in him was still there but was being turned by circumstance into a great geographer and explorer. He knew he was in the region where the Congo and the Nile must have their sources and was determined to settle that problem. In 1869 he reached Ujiji, the headquarters of the trade in ivory and slaves, but as a desperately ill man, and only to find the stores which had been sent from the coast plundered and dispersed. It is doubtful whether the Arabs would have allowed him to go down to Zanzibar even if it had occurred to him. Instead, he spent the next two years striving to explore the upper Congo which he hoped might turn out to be the Nile, and there he witnessed a wholesale massacre by the slave traders which finally turned him from further association with them. He struggled back to Ujiji at the risk of his life, a broken and disappointed man.

Help then arrived in the form of the journalist-traveler, Henry Morton Stanley (*q.v.*), sent out by his American newspaper with the bare instruction of "Find Livingstone." Together they discovered that Lake Tanganyika could not be part of the Nile system, but Stanley could not persuade Livingstone to return with him to the coast. He had become strangely dedicated to the task of finding the source of the Nile, the geographer in him was now pre-eminent. In Aug. 1872 he received reinforcements of stores and men sent back to him by the loyal Stanley and he started on his last journey with the best party he had ever had, proposing to go to the south of Lake Bangweulu to find the source of the Nile or the Congo, he was never sure which it would be.

He took the difficult route down the east side of Lake Tanganyika so as to complete his survey and found himself entangled in the swampy region of Lake Bangweulu in the middle of the rainy season. For once his magnificent navigation was at fault, because of an accident to his sextant, and for a while he was lost. His attacks of dysentery were now almost continuous, but impatient

to finish he started across the great swamps and reached the southern side a dying man, though continuing his mapping to within a day of his death, at a tiny village called Chitambo's in the district of Ilala.

The epic story of how his men embalmed his body and took it with his papers back to Zanzibar is perhaps the finest epitome of his life; he had become the "beloved master" of thousands of Africans and the remnant of these dared all risks to take him back to his own countrymen.

In the history of exploration there are other instances of lone travelers sojourning for years in far countries, but none is so well documented by the writings of the man himself. A poor speaker but a forceful writer with a delightful, if sardonic, humour, he lives now largely through his letters. Like many other great men he had the faults of his virtues. His failure as a leader of white men is an instance; for as his grandson, Hubert Wilson, has said, "He could only see black and white, he had no notion of grey." As a traveler and an observer he was supreme, but his fame really rests on his dedication to the welfare of the African, diverted by the slave trade from straightforward teaching of the gospel to other means of saving the people he had looked upon as brothers from his very first acquaintance with them.

LIVINGSTONE, the southern port of entry into Zambia and capital of the Southern political division, lies on the north bank of the Zambezi River, which there forms the border with Rhodesia. Pop. (1961/63) 33,440. The Victoria Falls, the Wankie and Kafue national parks, and Lake Kariba (*q.v.*) are nearby, and there is a 673-ac. game park along the Zambezi. The Rhodes Livingstone Museum, which dominates Mainway, has a unique collection of ethnological, archaeological, and historical exhibits, particularly those relating to Livingstone. Barotse Centre is the town park, and there are sporting facilities on the Zambezi. There are all grades of schools, hospitals, and places of worship for all denominations.

The town is on the main railway system of southern Africa and has good road connections and an international airport 4 mi. (6 km.) NW as well. Livingstone is a distributing centre for agricultural products and timber; secondary industries include the Zambezi sawmills, blanket weaving, and the making of furniture and steel river barges.

The first settlement was at the Old Drift ferry station, upriver on the Zambezi, in the 1890s; the town was established on its present site in 1905 with the completion of the Falls Bridge and the railway line. It became the capital of Northern Rhodesia (now Zambia) in 1907 and remained so until 1935 when the capital was moved to Lusaka. Livingstone (named for the missionary-explorer) became the country's first municipality in 1927.

(M. J. M.)

LIVIVS ANDRONICUS, LUCIUS (c. 284–c. 204 B.C.) the founder of Roman epic poetry and drama. His name shows that he was Greek and manumitted by a member of the Livian family; he may have been captured as a boy when Tarentum surrendered. He earned his living in Rome as a teacher of Greek and Latin, and it is probable that his main work, the *Odusia*, a translation of Homer's *Odyssey*, was intended as a schoolbook: Horace still read it at school. It was written in the rude Saturnian verse (a few hexametrical fragments belong to a later reworking in that metre) and, to judge from less than 50 surviving lines and the comments of Cicero and Horace, had little poetic merit. But it was both the first major poem in Latin and the first example of artistic translation, and the subject matter was happily chosen for the purpose of introducing Roman youth to the Greek world.

In 240 B.C. Andronicus produced at the *ludi Romani* a translation of a Greek play, probably a tragedy, and perhaps also a comedy. After this, the first dramatic performance ever given in Rome, he continued to write and stage both tragedies and comedies, from 235 onward in rivalry with Naevius. Only three titles

of his comedies are known, each represented by one fragment. The titles of his tragedies (*Achilles, Aegisthus, Ajax, Andromeda, Danae, Equos Troianus, Hermione, Iphigeneia, Tereus*) show that he translated mainly the three great tragedians, Aeschylus, Sophocles and Euripides. Fewer than 40 lines have survived. The skilful adaptation of the Greek iambic and trochee metres, long considered his personal achievement, is rather the result of popular borrowing before his time.

Livius is reported to have taken part in his plays and, when his voice failed, to have had the arias sung by a boy behind the stage, while he himself acted a dumb show. In 207, to ward off menacing omens, he was commissioned to compose an intercessory hymn to Aventine Juno, to be sung by a procession of 27 maidens. It is related that, as a reward to him for the success of this intervention, the guild of poets and actors was granted a place of meeting in the temple of Minerva on the Aventine.

LIVONIA, the Latinized form of LIVLAND, the name given by the Germans in the 12th century to the lands on the eastern coast of the Baltic north of Lithuania, as the first people encountered by them there were the Livs, a Finno-Ugrian race (cf. the ancient form *Liflandi*, found in a runic inscription of c. A.D. 1030). In its most extended sense, the name was understood to cover practically all of Latvia and Estonia (*q.v.*), the conquest and Christianization of which was begun by the Order of the Brothers of the Sword, founded in 1202. This order in 1237 became the Livonian branch of the Teutonic Order (*q.v.*), which continued its wars of crusading and colonization not only against the local pagans but also in rivalry with their Lithuanian and Russian neighbours. The conquered territory was divided between ecclesiastical states (bishoprics, under the archbishopric of Riga), lands ruled directly by the Order, and free towns.

This greater Livonia was dismembered in the course of the Livonian Wars (1558–83), which the Russian tsar Ivan IV the Terrible undertook to prevent Sigismund II Augustus of Poland-Lithuania from bringing the whole area into his sphere of influence. To save themselves from the Russians the Germans under the treaty of Wilno (Vilnius) of 1561, ratified in 1562, agreed that the region north of the Daugava river, including eventually Riga, should be incorporated with Poland, while Courland (*q.v.*) became a secular and hereditary duchy to be held as a Polish fief. The Swedes meanwhile took advantage of the situation to seize northern Estonia (also in 1561). These dispositions were maintained when Ivan came provisionally to terms with the Poles (1582) and with the Swedes (1583).

In 1621 the Swedes took Riga and Jelgava (Mitau), the capital of Courland. A Polish-Swedish war over Livonia followed. By the truce of Altmärk (1629), not only all Estonia but also the greater part of the Latvian country to the south, namely the Lutheran area called Vidzeme in Latvian, were assigned to Sweden; but the Catholic southeast of Livonia, namely Latgale, remained with Poland, with the name *Infanty Polskie* (Polish Livland).

In 1654 Livonia became the theatre of a triangular Russo-Polish, Polish-Swedish and Russo-Swedish war. The Polish-Swedish war ended with the treaty of Oliva (May 3, 1660), whereby Poland finally recognized Sweden's sovereignty over the territory ceded at the truce of Altmärk, with Riga. By the Russo-Swedish treaty of Kardis (1661), Russia renounced all claim to Livonia. The Russo-Polish war ended in 1667 by the peace of Andruszow (Andrusovo).

In the great Northern War (*q.v.*) Peter the Great won the whole of Swedish Livonia for Russia, his possession of it being confirmed by the treaty of Nystad (1721). Latgale was annexed to Russia at the first partition of Poland (1772), Courland at the third (1795). Under the Russian regime the historic Livonia was divided into three "governments": the Estonian (*i.e.*, the northern part of ethnic Estonia), the Livonian (*i.e.*, the southern part of ethnic Estonia and northern Latvia) and the Courland. When

after the Russian revolution of Nov. 1917 Estonia and Latvia proclaimed their independence, their common frontier was drawn across the Livonian "government," according to the ethnic boundary.

The name Livonia is sometimes used in a limited sense as the equivalent of Vidzeme, one of three historic constituents of Latvia.

LIVONIAN SWITZERLAND, a hilly district of great scenic attraction in the eastern part of the Latvian Soviet Socialist Republic, U.S.S.R., frequented both in summer and winter by tourists. The name "Switzerland" is applied in particular to the district of the upper Gauja valley, where the river cuts into the surrounding Vidzeme upland, the highest area in Latvia. Nowhere is the upland more than 1,040 ft. above sea level, but the morainic hills are sharply dissected and steep wooded slopes are characteristic. Popular summer resorts include the towns of Sigulda (Segewold), Ligatne (Ligat) and Cesis (Wenden).

(J. P. Co.)

LIVY (TITUS LIVIUS) (c. 59 B.C.–A.D. 17), most famous of Roman historians, was born at Patavium (Padua), Italy. Considering how celebrated he was in his day, remarkably little is known about his life. Even the date of his birth is not certain, since Jerome, in his history dealing with the year 59 B.C., links it with that of Messalla Corvinus, who was in fact born in 64 B.C. According to Quintilian, Livy had a son, who may have been the geographer cited by Pliny, and Seneca states that he had a daughter, who married a rhetorician L. Magius. If the T. Livius of a Paduan inscription of this period is the historian, he had two sons. He soon made his mark in literary circles at Rome, and it is known that Augustus was interested in his work, certainly in the early part of it. It may be assumed that he remained in favour despite his praise of Pompey and his doubts concerning Caesar, quoted respectively by Tacitus and Seneca, for he was able to encourage the later emperor Claudius in his youthful historical studies. Livy's fame throughout the empire is illustrated by the story of the man from Gades in Spain, who journeyed to Rome solely to see him. He presumably traveled; yet most of his time must have been spent at his desk in Rome or Padua. His work brought glory to Padua as can be judged from Martial's words *Censetur Apona Livio suo tellus* ("The Aponian land is celebrated for its son Livy"). His portrait may survive in a 3rd-century mosaic at Trier, Ger.

There is evidence for Livy's studies in rhetoric, and it is relevant to his historical methods. As a rhetorician he stood in the tradition of Cicero. "Read Demosthenes and Cicero," he wrote in a letter to his son, "then others as each is most like to Demosthenes and Cicero." He opposed Sallust and those who attempted a severe style by writing obscurely—*orationis obscuritatem severitatem putant*—and he condemned *verba antiqua et sordida* ("archaic and vulgar words"). Quintilian makes it clear that in the literary controversies of his day he carried on the campaign which Cicero had waged for a pure Latinity, without archaism or vulgarity. His position is not affected by Asinius Pollio's charge of *Patavinitas* which suggests a certain "provincialism" (*rusticitas*) by the standards of the Roman capital (*urbanitas*). In a literary sense the charge—for what it is worth—reflects upon his actual writing, not upon his theoretical views; but Pollio may have directed it originally against what he regarded as Livy's naïve treatment of Roman history. According to Seneca, Livy extended his interests to the composition of philosophical dialogues, including dialogues that were historical in character. Here again the influence of Cicero may be seen, particularly of his *De republica*. But Livy's great achievement lay in the application of his historical feeling and literary art to the writing of a full-dress history of Rome.

THE HISTORY OF ROME

Subject.—Livy's *History of Rome* (*Ab urbe condita libri*) was in 142 books and covered Roman history from the arrival of Aeneas in Italy to the death of Drusus, brother of the emperor Tiberius, in 9 B.C. After a formal preface, book i treated the origins of Rome and the regal period; books ii–v, the history of the republic to the sack of Rome by the Gauls (390 B.C.); books

vi-xv, the conquest of Italy; books xvi-xx, the First Punic War; books xxi-xxx, the Second Punic War; books xxxi-xl, the conquest of the east to the death of Philip V of Macedonia; books xli-xlv, the Third Macedonian War. So far Livy had composed his work in groups of five or ten books, and in a preface to book xxxi he refers to the two previous groups of 15 books; later the subject matter makes this arrangement impossible. Livy treated the Third Punic War and destruction of Corinth (146 B.C.) in books xlix-lii; the Gracchan period in books lviii-lxi; Marcus Livius Drusus and the Social War, with events to the death of Marius, in books lxxi-lxxx; and reached the death of Sulla in book xc. After the rise of Pompey and Crassus, Caesar's consulship and the first triumvirate are dealt with in book ciii. Books cix-cxvi on the civil war constituted a group that was called *Belli civilis libri* i-viii, closing with the assassination of Caesar (44 B.C.). Books cxviii-cxxxiii continued the work to Actium, and books cxxxiv-cxlii carried the history of Augustus' reign to the death of Nero Claudius Drusus (9 B.C.). The division of the whole work into decades is not attested before the 5th century A.D., although it may have been done by the book publishers of the 4th century.

There are some indications of the dating of publication. When Livy in the preface charges Rome with enduring neither vices nor their remedies, this may reflect the situation following Augustus' attempt at moral reform in 28 B.C. In i, 19, 3 he refers to the closing of the temple of Janus in 29 B.C. but not to its next closing in 25 B.C., and uses the name Augustus, which was conferred on Octavian in Jan. 27 B.C. The beginning of publication may therefore be dated in 27-26 B.C. Livy's silence at ix, 18, 9 about any return of Roman standards by the Parthians indicates that book ix appeared before 20 B.C. On the other hand, if xxviii, 12, 12 presupposes Agrippa's Spanish campaign, it cannot be dated earlier than 19 B.C. Book lix mentions Augustus' recital in 18 B.C. of Metellus' famous speech on marriage. If book cxi appeared after Augustus' death, this leaves Livy publishing the large number of 21 books between A.D. 14 and 17; but he may have been ahead with his writing. In any event it may be supposed that he died with pen in hand.

Of Livy's immense work only 35 books survive: books i-x, xxi-xlv (some lacunae in xli-xlv); with a long fragment from book xci (in a Vatican palimpsest). Some quotations were given by later authors, notably two passages about Cicero quoted in Seneca's *Suasoriae*. For the rest information can be derived only from material already reduced to epitome scale. An epitome of Livy had already appeared in the 1st century A.D. of which Martial wrote *pellibus exiguis artatur Livius ingens* ("in tight skins huge Livy is constricted"). It has perished, and the lost books (excepting cxxvi-cxxvii) are now represented only by the *Periochae*, or summaries of contents (probably of the 4th century); the Oxyrhynchus papyrus epitome of books xxxvii-xl, xliii-lv (written c. A.D. 300) may be noted. The *Prodigiorum Liber* of Julius Obsequens preserves a list of prodigies from the years 190-12 B.C., and the *Chronica* of Cassiodorus a list of republican consuls. Some information can also be verified from such writers as Orosius, Florus, Eutropius and Rufius Festus.

Sources and Composition.—In studying the history of Livy it is necessary to refer again to Cicero, whose work gave guidance to Livy in the theory and practice of historical composition. Both men believed that history as *magistra vitae* ("guide to life") had a moral purpose, which could only be achieved by rhetorical presentation: *opus unum hoc oratorium maxime*. The first law of history was to tell the truth, and the whole truth; but this established merely the *fundamenta*. One must build up the historical narrative (*exaedificatio*), wrote Cicero, and embellish it in literary style (*exornatio*), so that history should take on a form befitting its dignity; previous writers had been no more than chroniclers. In Cicero's view Rome lacked a history worthy of its greatness; *abest enim historia litteris nostris* he said in the *De legibus*. Such was the challenge and Livy took it up.

Yet Livy was also the heir of the Roman annalistic tradition, which, if it is judged by broader principles than those of Cicero's rhetoric, had already developed a powerful and impressive character. At the outset Roman folklore and Greek mythography com-

bined to enlarge upon the foundation legends of Rome. Naevius and Ennius gave the traditions a strong epic flavour, and Ennius, working through the annalists, influenced the first books of Livy. The senatorial historians from Fabius Pictor to Acilius also provided material about early Rome and, again, about their own period; and Fabius and Acilius were used by later annalists, thus in their turn reaching Livy. After Cato the antiquarian history of Calpurnius Piso gained special authority. In the Gracchan period two important developments occurred: first, the *Annales Maximi* made more archival material available under a yearly or annualistic arrangement that preserved its official appearance; secondly, the adoption of rhetorical methods of composition allowed the annalists to elaborate this material within its ceremonial framework. By the time of Sulla the annalists had established their genre of Roman historiography as it is found in Livy—traditional in content, form and expression, yet contemporary in its appeal. Claudius Quadrigarius may be noted in archaic style and Valerius Antias with conscious rhetoric, followed by Licinius Macer and Aelius Tubero, who submitted the traditions to fresh treatment.

Among these annalists Livy found his historical material already arranged in a form which provided both a chronological order and a traditional setting. In books i-iv he used Valerius Antias, Licinius Macer and Aelius Tubero, and in book v also included Claudius Quadrigarius, who had begun his history with the Gallic sack of Rome. He continued with these sources in books vi-x and (presumably) in the lost second decade. The Second Punic War allowed wider scope. In books xxi-xxx Livy kept Valerius Antias and Claudius Quadrigarius, dropping Macer and Tubero, and added fully descriptive material from Coelius Antipater's historical monograph on the war and from Polybius' "universal history" of the period 220-146 B.C. In books xxxi-xlv he used Valerius Antias and Claudius Quadrigarius, supplemented elaborately for events in the east from Polybius. He continued to the Sullan period with Antias and Claudius Quadrigarius, adding other sources, e.g., possibly Poseidonius, who cannot be identified from the *Periochae*; and later he may have used, among others, Sulpicius Galba, Sisenna and Caesar. Livy does not seem to have used the older annalists directly, and his references to Fabius Pictor, Cato and Calpurnius Piso, as well as to Silenus on Hannibal, were most probably at second hand. At special points, e.g., on the trial and death of Scipio Africanus, he might consult other authorities; but this is a rare occurrence in the extant books.

Method.—Livy did not claim to have studied his sources thoroughly. He recognizes the legendary character of the earliest stories and expresses doubts about the traditions before 390 B.C. "I should be satisfied to take as true what appears to be true" he writes. In some passages he may prefer the oldest historian, e.g., Fabius Pictor; in others the most authoritative, e.g., Polybius and he cites Valerius Antias' casualty figures skeptically throughout; sometimes he may even reject all the authorities. Yet for the most part he either judges on superficial grounds of probability in each instance or refrains from judgment entirely; for his comparison of variant details at the end of each section is conventional. In fact, despite his show of criticism, his method is basically uncritical. He did not inspect official documents; nor did he examine the inscription on the breastplate of A. Cornelius Cossus when Augustus raised the question of Cossus' *spolia opima* (spoils offered by a general who had killed an enemy leader in single combat), or the *libri lintei* (ancient records written on linen) when Macer and Tubero cited them differently. The set form of his annalistic sources enabled him to compose his work by the simple expedient of switching from one to another, as each offered the most immediately attractive material, and he incorporated episodes from other authors directly into his annalistic framework. He rendered all this subject matter, normally from one source at a time, without reconciling it with his previous narrative. As a result his history is disfigured everywhere by a multitude of inconsistencies, which fall in a pattern of change between sources from section to section.

The chief examples of this method must suffice. In dating events by years *ab urbe condita* Livy gives three systems; even in dating by consuls his use of different annalists, especially

Licinius Macer, has involved him in confusion. His description of the Roman disaster at the Caudine Forks (321 B.C.) represents the most tendentious tradition and is insufficiently corrected by his notes of variants. At the opening of the Second Punic War, as he admits, he is unable to clarify his chronology; and in following Coelius for Hannibal's crossing of the Alps—in agreement with Polybius, since both Coelius and Polybius drew upon Silenus—he inserts a passage in book xxi from another source which temporarily makes nonsense of the itinerary. In recording Spanish events in books xxxi–xlv he regularly refers to the governors—they were praetors with proconsular command—as both praetor (or *propraetor*) and proconsul, because the annalists differed in their titulature. When he incorporates Polybius on the Roman campaigns in the east, which Polybius reported under Olympiad years (autumn to autumn), he sets these sections under the Roman year (spring to spring) without any adjustment, and it is only the fact that very little happened during the winter that eases chronological difficulties. As regards his notorious “doublets,” or repetition of reports of the same event, these arise from the mechanical combination of his sources, where he moves from one to another without noticing the order in which they have arranged the respective parts of their narrative.

In writing up his subject matter Livy followed the rhetorical principles which Cicero had laid down in the *De oratore* for the composition of full-dress history. The historian must define the time and place of the action, show how it was conceived and executed, and explain its results, with attention to the character of the men in command. This kind of narration will be clear, since it is systematic, and—being circumstantial—it will produce a realistic impression in the mind of the reader. The effect may be increased by set descriptions of topography or battle scenes and the composition of speeches. In addition to this technique, as Cicero mentions in writing to Luceius, there was a “tragical” style of writing, in which the historian developed episodes as dramatic scenes, with vivid affecting detail, in order to inspire the reader, as if he were a spectator, with feelings of horror and pity. These methods had been practised in Hellenistic historiography, as is known from Polybius, who criticizes both the rhetorical procedure and Phylarchus’ use of “tragical” effects. It is worth noting that one treatment does not necessarily exclude the other in a writer who is the master of his presentation. Livy began with the ceremonial appeal of the annalistic material to the Roman reader and elaborated his episodes in the rhetorical manner, heightened by dramatic touches, without ceasing to interpret the course of events in the light of his own conception of history.

The results of this treatment can be seen throughout Livy's narrative, but it may best be illustrated where he has rendered extant parts of Polybius. In describing the siege of Ambracia (xxxviii, 3–7; Polybius xxi, 25–28) Livy enlarges on the topographical setting; at Cynoscephalae (xxxiii, 5–11; Polybius xviii, 18–33) he stresses the influence of terrain and weather on the battle; at the conference of Nicaea between Philip V of Macedonia and Flamininus and his allies (xxxii, 32–37; Polybius xviii, 1–12) he describes the scene, with its lively incidents, before proceeding to a sober account of the negotiations. His feeling for a dramatic occasion is apparent where he shows Flamininus proclaiming “the freedom of Greece” (xxxiii, 32–33; Polybius xviii, 46), and his sense of dramatic irony, where he recounts how the Aetolians failed to realize that surrender *in fidem populi Romani* was unconditional surrender (xxxvi, 27–29; Polybius xx, 9–11). The literary conventions of the rhetorical method appear when he presents the appeal of Antiochus III the Great to Prusias of Bithynia (xxvii, 25; Polybius xxxi, 11) in the fictitious form of a letter, which balances a letter from the Romans. Rhetorical argument, too, has its place. The Pergamene prince Attalus was in danger of being won over to Roman interests, and Stratus appeals to his loyalty (xlv, 19; Polybius xxx, 1–3) on grounds of honour and expediency: these are the rhetorical themes of *honestas* and *utilitas*, indicated by Polybius but more definitely formulated by Livy.

Such literary methods may be necessary, if only for the sake

of the reader, but they should be based upon full knowledge of the evidence. The armchair writer, as Polybius points out, may sacrifice historical accuracy in elaborating material without knowledge of the local conditions. Livy is conscientious, systematic and vivid; but he may misrepresent the original account by trying to clarify it, especially where he is dealing with Hellenistic institutions or topography. It is bad to take an Aetolian meeting at Thermum for an Amphictyonic meeting at Thermopylae (Polybius xviii, 48, 5; Livy xxxiii, 35, 8); it is worse to turn a disorderly engagement at Cynoscephalae (Polybius xviii, 18–33) into a set battle piece (Livy xxxiii, 5–11); but what would Polybius have said of a historian who—misunderstanding his technical term for “laying” spears to the charge position—made the Macedonian phalanx “lay down” its spears because of their unwieldy length (“*longitudo impedimento erat*”) and fight with swords? However, this is an extreme example, and for the most part, and especially where he was dealing with more familiar Roman conditions, Livy faithfully passes on his subject matter little affected by the rendering into more readable Latin.

Style.—According to Cicero, again, in the *De oratore*, the style of historical writing should be comprehensive and smoothly flowing, that is, a periodic style; which would allow the historian to present a complex account with logic and force, relating its elements to one another syntactically so as to keep the main action moving forward. Livy followed this principle, so important for a long history. Quintilian praises him for elevated but natural writing, mentioning his “flowing style” (*lactea ubertas*) and “brilliant lucidity” (*clarissimus candor*), words which define the chief virtues of the periodic style. It should be noted that Livy wrote with force as well as fullness. He uses elaborate sentences to set out the circumstances and preparation of the main action, which he then describes in rapid, short sentences, adapting his composition to the rhythm of the events. Almost any page will provide illustrations; but his vigorous story about Hercules and Cacus (i, 7) in contrast to the leisurely account of Dionysius of Halicarnassus (*Roman Antiquities* 1, 39), who was in the same rhetorical tradition, may be particularly noted. Livy handles with equal facility the plain reporting of official matters, the vivid description of dramatic episodes, and the oratory of his speeches. Where he falls into difficulty through overconcentration in his sentences, this is usually due to the pressure of the forward movement of his narrative. Further, the freedom with which literary convention allowed a historian to draw upon all the resources of the Latin language for colour and warmth enabled him to present the “epic” story of early Rome in “poetical” style; this is seen in the story of Hercules and Cacus and in his rendering in book vii of Claudius Quadrigarius’ account of the combat of Manlius Torquatus and a Gaul. He also developed ceremonial and ritualistic expression, in the annalistic tradition, for emotional appeal; e.g., in describing in book vii the combat of Valerius Corvinus and a Gaul. That he would always raise his style in this way is proved by his impressive account of the siege of Abydos (xxxi, 17–18), based on the prosaic Polybius (xvi, 30–34).

Conclusion.—When Livy's work has been considered in terms of subject matter, historical setting and literary influences, there still remains the quality of his achievement, which transcends the technical and the contemporary. That he was uncritical by modern standards is undoubtedly true; yet he has passed on the traditions of Rome as they came to him, and uncritical transmission may be preferred to unsystematic rationalization. His material, then, is worth having, and where his work is lost the historian labours under a serious disadvantage. Even allowing for his idealization of the past, he preserves the standards of public conduct which had raised Rome to greatness and which Augustus, relying on Italian sentiment, hoped to recall. As the republic fell into civil strife, he could lift his history above the bitterness of party feuds—“Pompeian” though he was—to a level of national interest and present it in the light of Rome's destiny. Lacking cynicism, he wrote to inspire patriotism.

Yet Livy's history has more than a Roman appeal—or rather, where he is thinking of the men and events of Rome, he portrays Rome in the light of men and events, which he describes and in-

terprets in universal terms. It is no coincidence that he treats the Greeks struggling under the shadow of Rome as carefully as he treats the Romans. There is a quality of sympathy in his work that arises from his understanding of human nature, and—though he may fail in the finer distinctions—he succeeds in his main purpose, especially where he depicts not only individuals but groups acting under the stress of emotion. Herein lies the true greatness of Livy's history. His imagination fuses and fires his rhetorical technique and stylistic skill, giving spontaneity to his composition, so that he stirs the mind and moves the heart. The Romans of his day felt his power; Romans of the later empire looked to him to revivify their pagan traditions; and men of the Renaissance—such men as Petrarch and Machiavelli—took his instruction into their own experience. Since modern criticism has done its work on his subject matter, it is permissible to return to his historical conception and the artistry with which he has presented it.

LI YUAN-HUNG (1864–1928), president of the Chinese republic, was born in the province of Hupeh, and educated at the Pei-yang naval college at Tientsin. He served in the navy during the war with Japan (1894–95) and later was in charge of fortifications at Nanking. He twice visited Japan to study its educational system and army organization. In 1911 he had risen to the rank of divisional commander in the army and was among the first military officials to realize the force of the revolutionary movement. In consequence he was empowered to negotiate peace at Shanghai, and upon the foundation of the republic became its first vice-president in 1912.

Upon the death of Yuan Shih-k'ai in June 1916 Li Yuan-hung succeeded as president and held office until the temporary restoration of the boy emperor in July 1917, when he resigned, remaining for the next five years in Tientsin. In 1922 he was prevailed upon to resume the presidency, but in September of the following year he was compelled to resign in favour of Tsao K'un. Li Yuan-hung at an early date opposed "Tuchunism"; i.e., the system of military governorships, and advocated divesting the tuchuns of administrative duties; he worked for the reunification of the country by negotiation instead of by force but was unsuccessful. He died in retirement at Tientsin on June 5, 1928.

LIZARD, common name for scaly-skinned reptiles of the sub-order Lacertilia or Sauria, who, with their close relatives the snakes (suborder Ophidia or Serpentes), constitute the dominant reptiles of the present day, the order Squamata. A relatively modern and still expanding group, the Squamata probably originated in Triassic times (extending from 200,000,000 to 160,000,000 years ago) from a group of extinct forms, the Eosuchia, that had earlier given rise to another stock, of which there is a single surviving species, the tuatara (*q.v.*). Both the lizard and the snake differ

from the tuatara and from crocodilians in many anatomical features, of which the most significant, as an indicator of relationship, is the presence of not more than one bony arch across the temple, instead of two. Lizards are usually distinguishable from snakes by the presence of limbs but some lack limbs, and no single character distinguishes the two groups absolutely.

Distribution.—Like all the other cold-blooded (more accurately, poikilothermic) animals whose body temperature fluctuates and is determined by that of their environment, the lizards flourish most abundantly in tropical and subtropical regions, the numbers of individuals and species diminishing toward the northern and southern borders of the temperate zones; only a few species penetrate to the Arctic circle or slightly beyond it, the limit being set by the presence of permanently frozen subsoil which prevents hibernation out of reach of frost. Like all reptiles, lizards have no physiological means of controlling their body temperature, which consequently varies with that of their surroundings. They habitually bask in the sun, for, until their temperature is raised to a certain level, they cannot achieve their full activity.

None of the present-day lizards is thoroughly aquatic (some extinct forms were), and none is an efficient flier; but lizards are adapted to almost every other environment and mode of life showing a correspondingly great diversity of size, shape and structure.

Structure.—As in almost all reptiles the skin has a protective layer of keratinous scales that is periodically renewed from beneath, the old layer being sloughed away. The shape and size of the scales vary in the different families and with the mode of life. In many active forms maximum flexibility of the skin is achieved by reduction of the scales to small, nonoverlapping granules; among desert dwellers there is a tendency for some scales, particularly those on the head and tail, to be enlarged to form spines. Burrowing and secretive forms have a slippery body surface due to the presence of smooth, highly polished overlapping scales. The skin is often reinforced by bony plates, which lie beneath the superficial scales (though corresponding with them in size and shape), these plates may form a continuous protective armour. Other defensive, or sometimes offensive, devices associated with the skin and scales are the occasional development of horns or fringing folds that break up the animal's outline and colouring. The colour pattern may be fixed and concealing by camouflage or there may be a highly developed mechanism for rapid colour change. The mechanism for colour changes consists of numerous star-shaped cells (chromatophores) each containing granules of pigment or a highly refractive substance, guanine. The granules are capable of movement within the cell and the cells themselves are capable of limited movement toward or away from the surface of the skin. Movement of a cell toward the surface and dispersal of its granules displays its particular colour to the maximum. Changes may result from the direct stimulation of the chromatophores by light or heat but the cells are under the control of the central nervous system. In consequence stimuli received through any of the sense organs may induce reactions and these will not be automatic and stereotyped but modified by such factors as associated memories and the individual's physiological condition.

The sense organs exhibit some modifications found also in other vertebrate groups, but a few are peculiar to the lizards or shared only with the snakes. Replacement of movable eyelids by a fixed, transparent, protective covering of the cornea—a characteristic of snakes—is found also in many lizards, but in the latter group a peculiar condition is sometimes found in which eyelids are normally movable but a transparent window is developed in the lower one. The median (parietal or pineal) eye of primitive vertebrates persists in some lizards in a more complete form than in any other living reptiles except the tuatara. Lying beneath a transparent scale on the top of the head, it is an eyelike structure that may or may not have a nerve connection to the brain; it appears to control the animal's activities in relation to the intensity of solar radiation. Another sense organ modification shared with snakes concerns Jacobson's organ, which in other vertebrates is part of, and continuous with, the olfactory system and functions as part

HARDUN, OR STARRED LIZARD

Agama stellio, a north African agamid that prefers a climate of extremely high temperatures

Tokay (*Gekko gekko*), largest member of the gecko family. It is found in Indo-Malaya, usually in or near areas of human habitation

Australian bearded lizard or bearded dragon (*Amphibolurus barbatus*), an agamid, in an attitude of defense with its throat puffed out and its mouth open

Meller's chameleon (*Chamaeleo melleri*), a large species found in Africa. True chameleons are found only in the eastern hemisphere

Underside of a Moorish or wall gecko (*Tarentola mauritanica*) showing the pads on the feet, an adaptation that permits this lizard to climb any kind of surface. It is found chiefly in north Africa, Spain and Yugoslavia

South African chameleon (*Chamaeleo pumila*), an arboreal species with a prehensile tail

AGAMIDS, GECKOS AND TRUE CHAMELEONS

Southern fence lizard (*Sceloporus undulatus consobrinus*), a spiny lizard of Texas and northern Mexico

Texas horned lizard (*Phrynosoma cornutum*), of southwestern U.S., the so-called "horned toad" sold in pet stores

Western collared lizard (*Crotaphytus collaris basleyi*), one of the lizards that runs on its two hind feet with its body upright. Found in western U.S.

Common or green iguana (*Iguana iguana*), which may grow to a length of more than six feet (including the tail). Found in tropical Central and South America

Close-up of the head of a male northern fence lizard (*Sceloporus undulatus hyacinthus*) showing the brilliant blue marking of the throat and side of belly. Ranges over east and south central U.S.

IGUANIDS

Brown colour phase of the green anole (*Anolis carolinensis*), also known as the American "chameleon." Ranges over southeastern U.S.

Close-up of the head of an eastern collared lizard (*Crotaphytus collaris collaris*). Found in central southern U.S.

Desert iguana (*Dipsosaurus dorsalis*) of southwestern U.S., a herbivorous species. Like several other iguanids, this species employs bipedal locomotion

Cuban ground iguana (*Cyclura macleani*), one of the most primitive types of Iguanas. Found on a few islands of the West Indies and Caribbean area

Marine iguana (*Amblyrhynchus cristatus venustissimus*) shown in its native habitat, the rocky shore of Hood Island, one of the Galapagos group

Rhinoceros iguana (*Cyclura cornuta*), one of the largest ground iguanas. The mottled appearance of this specimen is due to sloughing or shedding of the skin, a phenomenon usually associated with periods of growth in reptiles. Occurs on a few islands of the West Indies

IGUANIDS

Northern earless lizard (*Holbrookia maculata maculata*), a burrowing iguanid found from South Dakota to northern Texas

Side-blotched lizard (*Uta stansburiana*) of southwestern U.S. Scales in its tail, which catch into bark, adapt this iguanid for climbing trees, its usual habitat

Fringe-toed lizard (*Uma notata*), another burrowing iguanid found in the desert. When alarmed it buries itself completely in the sand

Chuckwalla (*Sauromalus obesus*), found in rocky, arid regions of southwestern U.S. and northern Mexico. When frightened the chuckwalla hides among the rocks where it inflates its lungs to wedge itself tightly within a crevice

Head of the common or green iguana (*Iguana iguana*) showing pattern of scales and detail of the sense organs and foreclaw

IGUANIDS

Blue-tongued skink (*Tiliqua scincoides*) of Australia, among the largest of the family, with a length up to about two feet

Western skink (*Eumeces skiltonianus*), which ranges from Canada to Baja California. The brilliant blue tail is common among young skinks of several genera

Trachysaurus rugosa, commonly known as the shingle-tailed or shingle-back skink. The scales overlap like those of a pine cone. Australian

Broad-headed skink (*Eumeces laticeps*), an arboreal, woodland species found in most of the south central and southeastern U.S.

African skink (*Mabuya perrotetii*). Other *Mabuya* species are widely distributed in tropical regions of both hemispheres

SKINKS

Red worm
of about 1

Amphisbaena alba) of South America. Reaching a length
this lizard is only occasionally seen above ground

Schelltopusik or glass lizard (*Ophisaurus apodus*), largest of the snakelike
anguid lizards, will grow to a length of almost four feet. Found in south-
eastern Europe and southwestern Asia

Six-lined racerunner (*Cnemidophorus sexlineatus*), found in southeastern
and south central U.S., is, like all race runners (or whiptails), noted for its
speed

Cnemidophorus lemniscatus, the strand race runner, of South America, uses
bipedal locomotion when running at top speed

Golden or northern tegu (*Tupinambis nigropunctatus*), one of the largest of the teiid family. Found in South America

WORMLIKE LIZARDS AND TEIIDS

Gila monster (*Heloderma suspectum*), one of two venomous lizards known (the other is the beaded lizard). Found in the southwestern United States and Mexico

Head of a jeweled lacerta (*Lacerta lepida*), of the western Mediterranean area, largest member of a family found throughout Europe and Africa

Indian yellow monitor (*Varanus flavescens*). Monitors constitute a family of large, carnivorous lizards widely distributed in Africa, the middle east, southern Asia and Australia

African savanna monitor (*Varanus exanthematicus*). Strong limbs and large claws characterize this family of lizards

MONITORS, LACERTIDS AND THE GILA MONSTER

of the sense of taste. In the Squamata Jacobson's organ is completely separated from the other nasal structures and appears as two separate pouches opening on the roof of the mouth. Into these pouches the tips of the forked tongue are thrust after they have collected particles from external objects that are being investigated, or even from the air.

Natural History.—Although the majority of lizards are creepers, they exhibit many modifications for locomotion in different environments. In those that scamper over loose, shifting sand, the area of the feet is increased by the development of lateral fringes on the digits. In those that climb among rocks or in trees, the hands and feet may have scales beneath them, usually spiny, acting as additional "claws," or adhesive pads. Chameleons, which are mostly arboreal, have digits bound together into opposable bundles like tongs, and prehensile tails. The larger and more active terrestrial forms, such as the monitors, can run with the body held clear of the ground, and some iguanas and agamas, when alarmed, can rise and run on the hind limbs only. Reduction of digits and limbs in connection with burrowing habits or life among dense, tangled vegetation has occurred many times.

Other modifications associated with burrowing habits are elongation and slimming of the body, elimination of a distinct neck, reduction of eyes, reduction of the outer and middle ear and the development of a smaller but more compact and stronger skull. In the truly subterranean lizards the tail is short and blunt, but the trend of those living in dense herbage is in the opposite direction, the tail being sometimes more than four times as long as the head and body. Gliding flight has been achieved by a few oriental species constituting the genus *Draco*, the so-called flying dragons. As in the gliding mammals (flying squirrels and flying lemurs) the wings are extensions of the skin on the flanks, but in the lizards this patagium is supported by five or six enormously elongate ribs. Flipperlike limbs for swimming were possessed by the extinct marine mosasaurs but no modern lizards are aquatic to the same extent, though many live in close association with fresh water, and one (*Amblyrhynchus*) with the ocean. These semiaquatic lizards swim readily by means of their laterally compressed tails, whose area is increased by crests of enlarged bladeliike scales. Many lizards can shed their tails as a defensive measure. If one of these animals is attacked, the tail may be broken off to the surprise and confusion of the assailant. The lizard suffers only a temporary loss, however, as a new tail regenerates from the stump (see REGENERATION).

The great majority of lizards are insectivorous, consequently there is relatively little diversification of the teeth, which are mostly simple and peglike. Even among the insectivorous forms, however, there may be some differentiation into incisors, canines and molars (though these are not homologous with the similarly named teeth of mammals) and the molars may be elaborated by the development of additional cusps even to the extent of being serrated. In some of the larger forms that tend to be omnivorous scavengers, the teeth are enlarged and strengthened. In herbivorous forms, notably among the iguanas and agamas, the anterior teeth may be fused together to form a long, cutting edge for grazing. Two unusual specializations for the capture of prey are found, one being the remarkably extensible tongue of the chameleons and the other the venom apparatus of the Gila monster and the Mexican beaded lizard.

As in all reptiles, fertilization is internal and the developing embryo is provided with an amnion and allantois. Secondary sex characters associated with courtship are of widespread occurrence in the different families. Frequently the males are brilliantly coloured during the mating season and there is usually a simple display pattern by this sex. This may consist in no more than bobbing of the head, but there is often inflation of the body, and more particularly the throat, which may be equipped with a specially dilatable and brilliantly coloured dewlap. In many male lizards, hedonic glands, whose secretion may or may not serve as a sexual attractant, open by pores on the hind side of the thighs or in front of the anus or vent.

The majority of lizards are oviparous, laying eggs with a tough parchmentlike shell; these are usually buried in the ground and

incubation is accomplished by the sun's heat. There are, however, many forms that retain their eggs in the oviducts, in some instances until the eggs are on the point of hatching. In these ovoviviparous forms the normal thick protective eggshell is reduced to a thin transparent membrane, which is ruptured by the young lizard at the moment the egg is laid. Rupture of the eggshell, whether there is external incubation or not, is facilitated by a special forwardly directed tooth on the middle of the upper jaw, the egg tooth, which is shed after it has served its purpose. In both the oviparous and ovoviviparous types the whole of the food material for the development of the embryo is provided by the egg yolk, but in some skinks, xantusiids and geckos there is true viviparity of a simple type; the eggs contain much yolk but the embryo is supplied additionally through a primitive type of placenta.

Classification and Survey.—The number of species of lizards extant today is of the order of 2,500–3,000. They may be grouped into 18 families based on certain anatomical features.

Gekkonidae (*Geckos*).—Most geckos have a soft, granular skin often beset with tubercles, and the vast majority lack movable eyelids. The family has a world-wide tropical and subtropical distribution and shows considerable tolerance of climatic and environmental conditions. Unlike the majority of lizards, which are sun seekers, many geckos are nocturnal, with contractile pupils, like a cat. Most species are climbers and have adhesive pads on the fingers and toes; one genus, the African *Lygodactylus*, also has a similar adhesive pad on the tip of the tail. The tail is extremely fragile in most geckos and is also more variable in shape in this group than in any other family. Geckos are often to be found in and about human dwellings; where sanitary arrangements are defective they may be carriers of pathogenic organisms such as *Salmonella*. (See GECKO.)

Pygopodidae.—This is a small assemblage of lizards, confined to Australia and New Guinea, that have some anatomical features in common with the geckos, but that are all snakelike and without functional limbs. None has movable eyelids nor any external traces of forelimbs, though there are vestiges of a shoulder-girdle; hind limbs are present as small scaly flaps on each side of the vent. They are semiburrowers, to be found in grass, among tangled scrub herbage or in loose soil. In the grass-dwelling forms such as *Lialis* and *Pygopus* the tail is inordinately long, up to twice as long as the body, and fragile.

Iguanidae (*Iguanids*).—This ancient and generalized family is confined in modern times to the new world and Madagascar, with a single form (*Brachylophus*) in the Fiji and Tonga islands. Presumably the family at one time had a world-wide distribution; one fossil genus has been found in Europe. (See IGUANA.)

Agamidae (*Agamids*).—This family is the old-world analogue of the Iguanidae. The two groups are mutually exclusive in their territorial ranges, the agamids being confined to Europe, Africa, Asia and Australia. Each group has invaded the same kinds of environment within its own territory with many strikingly similar evolutions of form. The agamids are mostly insect eaters; they have the teeth differentiated into simple incisors, enlarged canines and laterally compressed more or less tricuspid molars. The scales are relatively small (though they may form spines), there are no enlarged plates on the head (except for the scale under which lies the pineal eye) and there are no bony plates under the scales. Movable eyelids and limbs are always well developed and the tail is not capable of being shed and regenerated. The shape of the body varies considerably, ground-dwelling forms tending to be horizontally flattened and arboreal species to be compressed from side to side.

The genus *Agama* is a generalized, ground-dwelling type common throughout Africa, the near east and southeast Europe; most of the species are cryptically coloured in shades of brown, but the males often develop brilliant red or blue heads and throats, the latter being distended and pulsated in courtship.

Dilatation of the throat, and special structures developed in association with it, is a common habit throughout the family, the gesture being either part of a courtship display or a threat. In the Australian frilled lizard (*Chlamydosaurus*) the neck has an erectile collar, consisting of a fold of skin that, when not in

use, hangs like a cape about the shoulders. When the lizard is angered or frightened this cape is erected so that it stands out like an enormous ruff and at the same time the mouth is opened wide, displaying a saffron-yellow interior. The gesture is impressive but is mostly bluff, and if further molested the animal usually flees, running swiftly on the hind limbs only. This habit of running on the hind legs is shared by other members of the family, including *Physignathus*, found from Australia to Tonkin, some of whose species are semiaquatic, living on the banks of streams and taking to the water readily when disturbed.

It is in the Indo-Malayan region that the greatest diversity and the most bizarre developments are to be found. The extreme among the inexplicable modifications is probably in the East Indian water lizard (*Hydrosaurus amboinensis*), found in the Philippines, Java, Celebes and the Moluccas. This animal reaches 3 to 4 ft. in length, more than half of which is the tail, which has a high sail-like crest supported by enormously developed spines from the vertebrae. Like the iguanid *Basiliscus*, it has fringed toes that enable it to run across water. Horns on the tip of the snout, similar to those of chameleons, are found in genera such as *Ceratophora* of Ceylon and *Harpesaurus* of Java. Parallelism with chameleons extends also to the development of a prehensile tail (*Cophotis* of Ceylon, Sumatra and Java), to bony ridges above the eyes in *Lyriocephalus* (which also has a globular excrescence on the tip of the snout) and to remarkable powers of colour change in genera such as *Calotes*, which, like the American anoles (family Iguanidae), are sometimes erroneously known as chameleons. This phenomenon is associated more with emotional changes and physical conditions than with colour of the background and is most marked at the breeding season, either during courtship or when males fight. *Calotes versicolor*, known in some parts of its range as the bloodsucker, is extremely pugnacious during this period; the males develop a brilliant scarlet or crimson colour that may be restricted to the head and shoulders or may involve almost the whole of the body. The acme of specialization in the family is in the arboreal flying lizards (*Draco*) of the Malayan region.

Most of the forms hitherto mentioned are either insectivorous or have a mixed diet. It is surprising that the most exclusively herbivorous members of the group live in the Saharo-Sindian desert belt. They are the mastigures (*Uromastix*), heavily built lizards with short limbs and a short but heavy tail armed with whorls of strong spines. The presence of spines reaches its maximum in the Australian thorny devil (*Moloch*); this is a small, squat, short-tailed creature, liberally beset all over with spines, the largest being on the snout and above the eyes.

Chamaeleontidae (Chameleons).—These are arboreal lizards with many unique specializations, including the grouping of the fingers and toes to form opposable bundles for grasping twigs and branches and an enormously protractile tongue for catching insect prey. (See CHAMELEON.)

Xantusiidae.—This small Central and western American family comprises lizards with geckolike eyes lacking movable eyelids. The body is covered with small granular scales, with or without some scattered enlarged tubercles on its upper surface, but the lower surfaces and the top of the head have larger, platelike scales; there is no bony armour under the scales. *Xantusia* is found in the arid regions of the southwest of the United States, *Lepidophyma* and *Gaigeia* in Central America and *Cricosaura* in Cuba.

Scincidae (Skinks).—Skinks constitute the largest lizard family. A cosmopolitan group, its members have relatively large overlapping, platelike scales underlain by bony plates, which form a complete armour. Compared with such families as the Iguanidae and Agamidae, the skinks show relatively little diversity of form and scale modifications, nor have they powers of rapid colour change, though the colours are often brilliant. A widespread colour feature in the group is a sky-blue or turquoise tail, particularly in young individuals. In the vast majority, the scales are uniform in size and smoothly polished, but sometimes they have one or more raised longitudinal ridges (keels) that continue beyond their edges to form spines. In the Australian stump-tails (*Trachysaurus*), for example, the keels are wide and blunt and each scale resembles that of a pine cone; in the Australian

genus *Egernia* the keels are enlarged and prolonged to form effective, thornlike spines, particularly on the broad tail.

The family is noteworthy for the extent to which there is limb degeneration in association with burrowing habits. There is every gradation between well-developed limbs, each with five digits, and complete absence of any external traces of limbs. One evolutionary line in Africa culminates in a group of blind, limbless burrowers that is sometimes given family status under the name Feyliniidae. The American genus *Anelytropis*, sometimes placed in a separate family, is probably a parallel development.

Another modification of which gradational stages can be traced is the development of a fixed transparent covering over the eye, similar to that found in some other families and in all snakes. This modification may be associated with burrowing habits but is also found in some nonburrowers. In the most primitive condition the lower eyelid is still movable, but a few scales in the centre of it are enlarged and transparent; in more advanced stages, as for instance in the genera *Leiopisma* and *Emoia*, almost the whole of the lower lid has lost its scaly character and is transparent; the most advanced stages in genera such as *Panaspis*, *Ablepharus* and *Ophiseps*, have the lower lid immovable in the "closed" position and also more or less fused along its edge with the upper lid.

Most skinks lay eggs, but a few species of *Leiopisma*, *Himulia* and *Chalcides* are truly viviparous, the later stages of fetal development being nourished through a simple placenta (this phenomenon occurs also in two New Zealand geckos and in the family Xantusiidae).

The skink, the species that has given its name to the whole family, is a small desert-dwelling lizard of the Sahara and Arabian deserts. When dried, powdered and swallowed this lizard was formerly regarded as a panacea for many ills, and as an aphrodisiac, and is still esteemed by primitive tribes both as a food and a drug. It shares with a few close relatives from the same region the ability to "swim" through loose sand by modifications similar to the moles among mammals: it has a pointed, wedge-shaped snout, tiny eyes and short, broad, paddlelike limbs with broadly fringed fingers and toes.

Dibamidae.—This family comprises a single genus (*Dibamus*) of degraded, blind, burrowing lizards, of unknown ancestry, found from New Guinea to Annam and the Nicobar Islands. In females both the forelimbs and the hind limbs are absent; in males the hind limbs are represented by a pair of small scaly flaps. The general appearance is wormlike, both head and tail being of the same diameter as the elongate body and there being no recognizable neck. The snout is covered with a thickened shield and the eyes are minute and concealed beneath the skin. The body is covered with smooth overlapping scales with no bony armour beneath them. Reproduction is by eggs that, like those of the geckos, have a brittle calcareous shell.

Lacertidae.—These are the true lizards of the old world exclusive of Madagascar and Australasia; their northern limits coincide approximately with the southern edge of the permafrost zone (i.e., where the subsoil remains frozen even through the summer). They are the dominant lizards of Europe. All are terrestrial, and the family shows relatively little diversity of form and no tendencies toward limb degeneration. The head is covered by enlarged symmetrically disposed plates, each with a corresponding bony plate beneath it; the body scales, on the other hand, lack any such bones and are generally small and granular on the back, but enlarged to form rectangular plates on the under surfaces. The tail, almost always long and slender, is fragile.

The common or viviparous lizard (*Lacerta vivipara*), which occurs over a large area of northern Europe, is plentiful throughout Great Britain and also occurs in Ireland, though scattered there. The scientific name is slightly misleading since the species is really ovoviviparous and not viviparous; i.e., the eggs are retained within the mother's body until they hatch but the embryos obtain their nutriment solely from the yolk material in the egg; in the Pyrenees it has been reported that eggs may be laid before the young are ready to emerge.

The sand lizard (*L. agilis*) always lays eggs and, despite its scientific name, is a more heavily built and less nimble species.

Although common enough in north central Europe, this species is relatively rare in Britain and is restricted to a few areas of sand dunes or sandy subsoil. Females of the species are inconspicuously coloured, being gray-brown with longitudinal rows of large darker blotches enclosing white spots. Males, in the breeding season, are a beautiful dark emerald green, with a row of conspicuous black-bordered white circles on the sides of the neck and the flanks. Their colour sometimes leads to erroneous records of another species, the true green lizard (*L. viridis*), which is a much larger species common throughout western and southern Europe.

It is especially in the Mediterranean region that the genus *Lacerta* is dominant. Everywhere wall lizards are to be found, showing great variability, particularly in colour and pattern. Almost every small island has a recognizably different form; on the mainland, too, there are almost endless variations from place to place. Some of the colour forms are associated with special environmental conditions, and, in fact, may be caused by them; for instance, on small barren rocky islands where there is little or no vegetational cover, the lizards are almost always black or nearly so. But in most cases there is no obvious cause and effect relationship. Circular sky-blue spots on the flanks are of common occurrence in the family, and the handsomest of the European lizards, the eyed lizard (*L. lepida*), has rows of such spots, each one black bordered, on a green ground colour.

In Africa and the near east, lacertids show great tolerance of arid climatic conditions. *Acanthodactylus* has the area of the fingers and toes increased by fringes of elongate scales and is thereby enabled to run over soft sand. Probably in connection with life in desert and semidesert conditions the eyelids of lacertids have undergone the same modifications as those of other families, namely the development of a transparent window in the lower lid and, where the window is perfect, fusion of the lower lid with the upper so that the delicate cornea is completely covered. This condition is found in the Indian *Cabrita* and in *Ophiops*, a genus that ranges from Algeria to India.

Cordylidae.—The plated lizards and zonures from southern Africa and Madagascar resemble the skinks and lacertids. The head is covered with enlarged scales having bony plates beneath them; both the back and belly have relatively large, almost rectangular scales, which form linear series longitudinally and transversely over a bony armour. The result is a somewhat rigid shield on the back and a similar one covering the belly. Flexibility is provided in several of the genera by an inverted box pleat along each flank; this inturned fold of skin is covered with small granules and is devoid of bony plates. Most of the group have well-developed limbs, but *Chamaesaura* and *Tetradactylus* of South Africa show various stages in limb reduction, the most degenerate species being snakelike with limbs represented by mere stumps devoid of recognizable digits. *Chamaesaura* dwells in dense herbage and possesses to a marked degree the elongate tail often found in association with that environment; the tail is four times as long as the rest of the animal. *Cordylus* (*Zonurus*), on the other hand, is a rock dweller, and has a short tail with enlarged scales forming whorls of large spikes. These structures must surely deter would-be predators trying to extract the lizard from a cranny in which it has taken refuge.

Teiidae.—The typical members of this American family superficially resemble the Lacertidae of the old world, the head being covered with large symmetrical plates, the back usually with small granules and the belly with rectangular plates in regular transverse series. Genera such as *Kentropyx*, *Ameiva* and *Cnemidophorus* (race runners in the United States) found from the south and west of the United States and the West Indies to Patagonia, resemble the old-world genus *Lacerta* not only in general appearance but in the multiplicity of local races or subspecies.

The family as a whole, however, shows a much greater range of form and adaptability than the lacertids. The tegus (*Tupia nambis*), found from the Guianas to tropical Argentina, resemble the monitors (see *Varanidae* below) in size (up to 4 ft. or more), form and habits; they are general predators and scavengers. *Crocodilurus*, of the Amazon basin, is probably semiaquatic, and has a flattened tail with a double crest, like that of a crocodile.

Dracaena, another large species of the same region, has large oval crushing teeth in connection with its diet of mollusks. In the smaller forms there is progressive reduction of the limbs and development of a window in the lower eyelid: *Alopoglossus* of Ecuador and Peru has a few enlarged semitransparent scales on the lower eyelid; *Pantodactylus* of southern Brazil and northern Argentina is a rather elongate form with an undivided transparent disc; and *Gymnophthalmus* and *Micrablepharus* have, like some skinks and lacertids, the transparent lower eyelid fused with the upper. *Anadia* of Central America and Ecuador is elongate and has five digits on its limbs. *Scolecocaurus* is serpentine, with three or four clawed fingers and toes, and burrows in humus and rotten wood, feeding principally on termites.

Bachia and *Iphisa*, of northern South America, exhibit the greatest degree of degeneration in the family: the body is elongate and serpentine, the eye minute but still equipped with functional eyelids, the scales no longer granular or overlapping but squarish and arranged in regular longitudinal and transverse rows like those of the amphisbaenids (see below), the fingers reduced to clawless tubercles or quite absent and the hind limbs having perhaps a single toe. One of the most remarkable modifications is in the Trinidad species (*Protoporus shrevei*) that lives in the half-light of caves on Mt. Aripo. The males have a series of white spots along their flanks, each being a transparent area of thickened skin. These appear to be crude lenses, for it is reported that if a beam of light strikes the animal, each spot reflects it weakly.

Amphisbaenidae.—These wormlike creatures are highly specialized for subterranean life and they are probably not closely related to any other lizards. Only one genus, *Bipes* of western Mexico and Lower California, has any external trace of limbs; in it the forelimb alone persists and, though short, it has five, four or three digits. The head is always small, no wider than the body, and the bones of the skull are much stouter than in other lizards. Eyes are minute and completely covered by the skin though they may be visible through the scales. The conducting apparatus of the ear, instead of being connected to an ear drum to pick up sound waves, is connected with the lower jaw and chin to transmit soil vibrations. The head is covered by a few enlarged plates, but the outer covering of both head and body, though of the same horny material as normal reptilian scales, is a thin sheet. The skin on the body and tail is divided into small rectangular segments, which form transverse rings, and usually contains no pigment; in consequence the animals are always somewhat pink because of the blood colour showing through. The right lung is vestigial or absent.

The name, derived from Greek words meaning "both go," arises from the ability of these lizards to progress either backward or forward and from the fact that the tail is so short and blunt that, at a glance, it is scarcely distinguishable from the head. All the species are completely subterranean in habits and are predators on burrowing invertebrates, particularly ants and termites. They are found in the Iberian peninsula southward and across north Africa to southwestern Asia, and from the southern U.S. southward to Argentina. (See AMPHISBAENA.)

Helodermatidae.—This family contains the only known poisonous lizards, the Gila monster (*Heloderma suspectum*) of Arizona, New Mexico and Utah, and the beaded lizard or Escorpión (*Heloderma horridum*) of Mexico. These are sluggish, heavy-bodied creatures with weak limbs and short stumpy tails. The skin is beset with tubercles and presents a warning coloration of alternating rings of blackish-brown and yellow or pinkish-orange. The poison apparatus consists of a row of glands along the inside of the lower lip whose openings lie near the bases of the recurved, grooved teeth. When the animal bites, it deliberately chews the object; in this way a considerable amount of venom is worked into the wounds through the channels of the teeth. The food consists chiefly of small lizards on which the poison acts fairly rapidly. The bite is not, as a rule, fatal to man. (See GILA MONSTER.)

Lanthanotidae.—The rare Bornean lizard *Lanthanotus* was for a long time regarded as a close relative of the Gila monster, but has been shown to be allied to the monitors and even more closely to some of their extinct relatives, the mosasaurs and dolichosaurs.

Although it is by no means snakelike in general appearance, it possesses many of the structural features to be expected in an ancestor of the snakes, a fact that supports the hypothesis that the snakes are derived from some monitorlike lizard.

Anguidae.—This small family is chiefly American, but with a few species in Europe and the Indian region. All the species have large, overlapping scales with bony plates beneath them. *Gerrhonotus*, of North and Central America, and *Celestus*, of the West Indies, Central and South America, are genera with well-developed, pentadactyle limbs. *Ophisaurus*, which has the limbs reduced to a pair of small stylets on each side of the vent, has a peculiar distribution, species occurring in the United States, Mexico, India and Burma and in southern Europe and Morocco. The European species (*O. apodus*) is the "Scheltopusik" or glass snake, the latter name bestowed because of the extreme fragility of its tail, which, if the creature is roughly handled, breaks into several fragments. The American species have similar habits. *Anguis*, another genus, has no external rudiments of limbs. Its sole species, *A. fragilis*, known in England as the slowworm or blindworm, is a snakelike creature, frequenting grassy banks and ditches, and is one of the few animals that preys largely on slugs.

Xenosauridae.—This family comprises two montane lizard genera, one Mexican (*Xenosaurus*) and one Chinese (*Shinisaurus*). These forms resemble the Anguidae in many features, but differ, among other things, in a reduction of the subsurface armour. On the head the bony plates are consolidated with the underlying bones but elsewhere they are reduced to small isolated nodules. *Shinisaurus* looks like a miniature, foot-long crocodile and is semiaquatic. It frequents the banks of streams into which it plunges when disturbed, seeking refuge at the bottom under rocks and stones.

Anniellidae.—This family contains a single genus (*Anniella*) of elongate and limbless burrowing lizards related to the Anguidae. These wormlike lizards from California have no external vestiges of limbs and have the minute eyes covered by scales. The scales are soft and without bony plates. The colour is silvery, each scale edged with brown, and a narrow dark line courses down the middle of the back.

Varanidae (Monitors).—This old-world family of large lizards shows little diversity of form despite the fact that its members are successful in many different habitats. All are typically lizardlike in general appearance, with heavy bodies, slender tails that are not fragile, and with well-developed pentadactyle limbs armed with powerful claws. The neck is longer and more flexible than in most other lizards, and the tongue is snakelike, forked and protrusible. The head and body are covered with small granular scales and there is either no bony armour or the plates are small and widely separated.

The family is an old one, fossils as old as the Cretaceous being known, and it is closely allied to the extinct semiaquatic dolichosaurs and marine mosasaurs. The living varanids are found in Africa, Arabia, southern Asia and Australia. Some, such as the Nile monitor (*Varanus niloticus*) and the Indo-Malayan water monitor (*V. salvator*) frequent the vicinity of rivers and streams and take readily to the water, swimming by lateral undulations of their vertically flattened tails, the limbs being held close to the sides. Others, such as the desert monitor (*V. griseus*), which ranges from north Africa to the Caspian sea and northwestern India, are restricted to arid country. Others again are semi-arboreal. Most are adaptable and are not inseparably associated with any restricted environment. All monitors are carnivorous, most of them indiscriminately so, with no objection to carrion, and are active predators. Some will eat fruits, several regularly prey on the eggs of crocodiles and turtles, digging out the nests, and the semiaquatic forms often feed on fresh-water mussels.

Monitors are the largest lizards of the present time. The largest species is the Komodo dragon (*V. komodoensis*), found on the two small East Indian islands of Rincha and Komodo and on the adjacent part of Flores. Exaggerated and sensational stories accumulated around this creature, until it was studied in the field by E. R. Dunn in 1926. It has the heaviest build of any of the monitors, but it also has a relatively short tail so that a specimen

9 ft. long has a body three or four times as heavy and bulky as that of, say, a water monitor of the same over-all length. This led, by inapplicable arithmetic, to stories of 30-ft. specimens; the maximum size is probably about 10 ft. It is a diurnal animal that preys mainly on small wild pigs.

The largest number of forms is found in Australia, where the rare Queensland species (*V. giganteus*) closely rivals the Komodo dragon in size. Monitors can run at a considerable speed, though this, again, is often exaggerated and probably does not exceed 10 m.p.h., and that for only a short distance. When angered they inflate themselves, hissing violently, lashing the tail and threatening with widely opened mouth. The threat may be no idle one since both the bite and the tail slap can be effective. In some cases, however, this behaviour is mere bluff: the African savanna monitor (*V. exanthematicus*) will sometimes, after threatening, sham death, rolling over on its back and remaining inert until the danger is past. All monitors lay large oval, soft-shelled eggs, which are deposited in holes in the ground or in termite nests.

LIZARD PENINSULA (THE LIZARD), terminates in Lizard point or Lizard head, Cornwall, Eng., the southernmost point of Great Britain, in 49° 56' 30" N., 5° 12' W. The beam from the Lizard lighthouse is visible for 21 mi. The cliff scenery is magnificent; the coast is fretted into small bays, caves pierce the cliffs and bold isolated rocks fringe the shore; Kynance and Mullion coves are particularly beautiful. The dark green and purple colouring of the serpentine rock, of which most of the peninsula is formed, is remarkable; it is used for building and worked into ornaments. Most of the peninsula is 200–300 ft. above sea level and on the thin soil Cornish heath is a characteristic plant. Lizard Town, at the southernmost extremity, is a straggling village. The nearest town of importance is Helston (q.v.), 11 mi. N. by road from Lizard point. At Poldhu, 2 mi. N. of Mullion, a monument marks the spot where Marchese Guglielmo Marconi sent and received the first transatlantic radio messages in 1901. There are remains of ancient settlements. The name (Lis-ard) means "high court."

LJUBLJANA (Ger. LAIBACH; Ital. LYBIANA), the capital city of the People's Republic of Slovenia, Yugos., in the Ljubljana *stet* (district), lies on the Ljubljana river 153 km. (95 mi.) W.N.W. of Zagreb by road. Pop. (1961) 133,386. It is dominated by the medieval fortress of Grad, from which a magnificent view is obtained of the Slovene mountains. Below Grad is the oldest part of Ljubljana. In 1895 the town suffered severely from an earthquake but some parts built in baroque style were preserved. Buildings of interest include the Franciscan church and those of St. Florian and St. James (all 17th century), St. Nicholas cathedral and the Knights of the Cross and Ursuline churches (all 18th century). There are a national museum, a national gallery, an opera house and a university. Ljubljana is an important communications centre with rail and road connections with other parts of Yugoslavia and central Europe. The main industries include the manufacture of machines, cotton, wool, porcelain, paper, furniture, boots, tobacco, soap, pottery, fire hose, matches and chemicals; there is also brewing, distilling, tanning and brickmaking. The town is a tourist centre.

The Roman city of Aemona was founded on the site in 34 B.C. An important crossroad on the route to Pannonia (the Ljubljana gap), it was probably destroyed by Attila. In 900 it suffered much from the Magyars, who were defeated there in 914. In the 12th

century the city passed into the hands of the dukes of Carinthia. It was taken by Otakar II of Bohemia in 1270 and in 1277 it came under the Habsburgs. In 1320 it obtained town rights. Ljubljana was a Roman Catholic see from 1461. In 1809 the city was twice taken by the French and from that year to 1813 it became the general seat of the government of the Illyrian provinces. In 1821 the congress of members of the Holy alliance, known as the congress of Laibach, was held there. When the southern railway from Vienna was built in 1849, Ljubljana began to prosper. While under Austrian rule, it became a centre of the Slovene national movement, the first Slovene newspaper having been published there in 1797. It became part of Yugoslavia in 1918. (V. DE.)

LJUSNAN, a river of Sweden, flows from Härjedalen province on the Norwegian frontier east to Hälsingland province and then turns southeast to enter the sea at Ljusne. Its total length is 430 km. (267 mi.). There are no lakes in the headstreams but near Ljusdal are lakes Norra and Södra Dellen. The river lacks important tributaries; Voxnan enters near Bollnäs (created a town in 1942).

In its middle and lower courses Ljusnan is one of the major timber-floating routes of Sweden and Ljusne has important saw-mills; there are pulp mills at Mama, Bergvik and Ljusne. Ljusnan is not important for hydroelectricity. (A. C. O'D.)

LLAMA (*Lama glama*) and the smaller alpaca (*q.v.*), the two domesticated species of the camel family indigenous to South America, are thought by some authorities to be derived from the guanaco (*q.v.*). Fossils from Pleistocene deposits in Argentina indicate that the llama forms a distinct species. Apparently it was a vanishing relict during postglacial time and was saved from extinction only through domestication by aborigines. The achievement of the Incas in llama husbandry was a marvel to Spanish conquerors. Incas used llamas to carry burdens, as food for sacrifice in religious ceremonies, for their wool and hide and as a source of fuel (dried dung). No wild populations exist today. Llamas are still in common use by highland natives from Peru to northern Chile and Argentina. Only males over three years old are used as pack animals. A 200-lb. llama can carry 100 to 130 lb. for a three-week trip, averaging 15 to 20 mi. a day. High thirst tolerance, endurance and ability to subsist on a wide variety of forage are important advantages in crossing bleak Andean plateaus.

Loyalty and affection reach their limits, however, when llamas are overloaded or exhausted, at which time they lie down, hiss, spit and kick, refusing to move until relieved of some of the weight or until rested sufficiently to continue the journey. Although usually white, the animals vary in colour to solid black, with any combination of brown or black spotting between these extremes. The coarse fleece is inferior to the wool of the alpaca. Sheep have largely replaced the llama as a source of wool.

See also references under "Llama" in the Index. (H. K. B.)

LLANBERIS, a small town of Caernarvonshire, Wales, $7\frac{1}{2}$ mi. E.S.E. of Caernarvon by road. Pop. of civil parish (1961) 2,110. It is a favourite tourist centre, being situated between two lakes, Llyn Padarn and Llyn Peris, the latter of which lies at the foot of the fine Llanberis pass (1,169 ft.), and being also the starting point for the easiest ascent of Snowdon (*q.v.*), which rises to the southeast. At Llanberis is the station of the Snowdon railway. Nant Peris, the old village, is about 2 mi. S. at the foot of the pass. Near Llyn Peris are the ruins of the 13th-century Dolbadarn castle. Although picturesquely situated, slate quarrying has spoiled the appearance of Llanberis, but the great Dinorwic quarries export fine slate to all parts of the world. A road over Llanberis pass leads through Nant Gwynant to Beddgelert.

LLANDAFF (LLANDAF), a ward (since 1922) in the county borough of Cardiff, Wales, lies on the west bank of the Taff 2 mi. N.W. of Cardiff. Pop. (1961) 22,164. It contains the cathedral church of one of the six dioceses of the Church in Wales, embracing the populous region of Monmouthshire and a great part of Glamorgan. Traditionally Llandaff was claimed to have been founded as an episcopal see by St. Teilo in the latter half of the 6th century, but it came into existence as a see in the diocesan sense only after the Norman conquest when the delimitation of the boundaries of the diocese was the subject of acute controversy during the time of Bishop Urban (1107-34), who visited Rome in 1128-29 to press his case in the Roman Curia. It was in support of these claims that *Llyfr Teilo* (the *Book of Llan Dâf*) was compiled as a record of grants and privileges made to the see in earlier times in recognition of its ecclesiastical status. Urban began building the present cathedral structure on the site of an earlier one and the Norman chancel arch is of this period. The Early English west front is of later date, and was not completed until about the time of Bishop Henry of Abergavenny (1193-1215).

After the Reformation and during the English Civil War the cathedral, deprived of much of its revenues, became a prey to the weather. The southwest tower and a large part of the roof of the nave collapsed in 1703 and again in 1722-23. Later in the same century a small church in debased Italian style was built within the ruins, but it was not until the mid-19th century that the original church was restored to reveal much of its former dignity and grandeur.

The restored cathedral was almost totally destroyed in World War II during an air raid in which St. Michael's Theological college also suffered. Since then the cathedral has again been restored and now contains the figure of "Christ in Majesty" by Sir Jacob Epstein.

Geoffrey of Monmouth, the chronicler, died at Llandaff in 1155. The castle, which during the middle ages served as the residence of the bishops, was destroyed by Owen Glendower about 1403-04, leaving only the ruined gatehouse, which still stands. In the mid-19th century Llandaff court was acquired by Bishop Ollivant (1849-82) as the bishop's residence.

Among the educational institutions at Llandaff are the Cathedral school and the grammar school for girls, the latter maintained by money bequeathed by Thomas Howell, a merchant who died in Spain in 1540, and now managed by the Drapers' company as trustees of the charity. (W. RE.)

LLANDOVERY (LLANYMDDYFRI), a municipal borough in Carmarthenshire, Wales, lies 27 mi. E.N.E. of Carmarthen by road. Pop. (1961) 1,911. Situated on the river Towy, it is a market town serving the surrounding agricultural area. In the cobbled Market square stands the town hall (1857) and adjoining is the Market hall, with its clock tower listed as an ancient

LLAMA (LAMA GLAMA) AND YOUNG

monument. The church of Llandinat has a 15th-century tower, and one of its vicars was Rhys Prichard (c. 1579–1644), author of *Canwyll y Cymry* (*The Welshman's Candle*), a collection of religious poems marking the rise of popular poetry in Wales. The church of Llanfair-ar-y-bryn, mainly Early English, is built on the site of a Roman fort (probably called Alabum). The town has developed round the 12th-century Norman castle, bounded by the river Bran, and its remains overlook the cattle market and the Castle sports ground. Llandovery college, a public school for boys founded in 1848, is in Queensway. The town is served by the Western region of British railways line and is on the main London-Fishguard road. While mainly dependent on agricultural industry and a railway depot, it is the centre of a developing forestry area and has its own sawmills. Situated on the edge of the Brecon Beacons National park and in an area of great natural beauty, it is also increasingly a tourist centre. In 1485 Llandovery was incorporated by a charter from Richard III, a privilege confirmed by Henry VIII and by Elizabeth I, whose charter is still held by the corporation. (V. M. W.)

LLANDRINDOD WELLS (LLANDRINDOD), an urban district of Radnorshire, Wales, lies in a delightful setting on a plateau surrounded by hills, about 700 ft. above sea level, east of the river Wye and west of Radnor forest. Pop. (1961) 3,248.

The town is well laid out with broad streets, open spaces, including the Rock park with its international bowling greens, the recreation ground and the common with its beautiful 14-ac. lake providing boating and fishing. There is a free library (1911) and a small museum. The medicinal waters for which Llandrindod Wells is famous first became known about 1696. Its fame spread rapidly in the next 50 years, and many people came to take the waters, staying at farm houses nearby. The town developed slowly, most of it being built in the first half of the 20th century. It is now a popular health and tourist resort and is affiliated with the British Spas federation. It is the seat of county administration, and the inhabitants are mostly occupied in administrative and professional offices, shops, garages and personal service. There are good road and rail communications with the principal towns in south Wales and the Midlands. (W. E. PE.)

LLANDUDNO, a seaside town and urban district in the Conway parliamentary division of Caernarvonshire, Wales, is situated 47 mi. W.N.W. of Chester by road. Pop. (1961) 17,852. It lies between the limestone headlands of Great Orme (northwest) and Little Orme (east), on a peninsula formed by the Irish sea and the Conway river, and has two sandy shores. On Great Orme are prehistoric sites, including a camp and a burial chamber; copper mines, now disused, that were worked by the Romans; and the old parish church of St. Tudno, believed to occupy the site of an oratory erected by its patron saint in the 7th century. Llandudno has grown from a fishing village into a health and resort town with two golf courses, Alpine displays in the Happy Valley park, magnificent views from a marine drive encircling the Orme, and steamers operating from Llandudno pier to Liverpool, the Isle of Man and Anglesey in the summer.

Charles Lutwidge Dodgson (Lewis Carroll) frequently visited Dean Liddell and his daughter Alice at their residence in the town and a memorial to him stands on the west shore.

LLANELLY (LLANELLI), a seaport and municipal borough of Carmarthenshire, Wales, is situated on the Burry inlet (Carmarthen bay) at the mouth of the Loughor river, 19 mi. S.S.E. of Carmarthen by road. Pop. (1961) 29,994. The town derives its name from the dedication of the parish church to the Celtic saint Elli or Elli. With the beginning of the Industrial Revolution, Llanelly became important for its lead-smelting works, shipbuilding and flannel industries. In 1804 copperworks were established, but gradually the old industries were superseded by the manufacture of tin plate. The first tinworks opened in 1847, and others followed in 1852–53, until, in 1888, 92 mills were in operation. This industry declined when the Ebbw Vale strip mill was set up, and the town became a colliery centre and collecting ground for the anthracite from the Gwendraeth valley. Secondary industries, including potteries, iron foundries and chemical works, also grew up. The tin-plate industry was revived in the mid-20th cen-

tury by the opening of a cold reduction plant at Trostre, on the outskirts of Llanelly, to work with the huge Margam strip mills in Glamorgan. Other steelworks have also been built. In 1955 the Towy water scheme was opened. The port, which exported many tons of coal in the 19th century, ceased operating for trading purposes in 1951, but the north dock was let to the admiralty for the laying up of reserve fleet vessels.

Llanelly was a borough by prescription in the old lordship of Kidwelly; by royal charter granted by George V, it was incorporated in 1913. In the same year its first mayor presented Parr Howard to the town, the grounds of which are used for recreation and the house for a museum, art gallery and tearooms. The town also has a mining and technical institute, a junior technical school and a school of art. There are two miles of sand along the shore.

LLANGOLLEN, a market town and urban district of Denbighshire, Wales, lies 23 mi. S.W. of Chester by road. Pop. (1961) 3,050. The Welsh Dee winds through the town and is crossed by a 14th-century bridge. Plas Newydd, now a museum, was the residence from 1780 of the "Ladies of Llangollen," Lady Eleanor Butler (d. 1829) and Sarah Ponsonby (d. 1831), two eccentric spinsters of well-known Irish families. The remains of Castell Dinas Brân, built early in the 13th century, stand on a hill 1,000 ft. above sea level. The Cistercian Valle Crucis abbey, 1½ mi. N.N.W., was founded by Madog ap Gruffydd Maelor, in the year 1200. Eliseg's pillar, north of the abbey, is a remarkable 9th-century stone cross.

Llangollen is the home of the international musical Eisteddfod (q.v.), founded in 1946 and supported entirely by voluntary workers for the promotion of international peace and good will.

The town's industries include the manufacture of leather, woollen goods (especially flannel) and sheet metal; farming, forestry, seed packing, lithography and colour printing are also carried on. There is also a considerable tourist trade. (E. E. Ro.)

LLANIDLOES, a market town and municipal borough in the Montgomery parliamentary division of Montgomeryshire, Wales, lies in the Severn valley, 30 mi. E. of Aberystwyth by road. Pop. (1961) 2,375. The parish church of St. Idloes (a 7th-century saint) has a 14th-century tower capped with a wooden belfry of Welsh border type, and a fine early 13th-century arcade, transferred from Cwmhir abbey (Radnorshire) in 1542. The town grew up under the protection of its motte and bailey castle, and in 1280 Owen of Arwystli, prince of Powys, obtained a charter establishing the fairs and Saturday markets of Llanidloes. Full civic privileges, granted about 1300, are still retained. The half-timbered market hall, standing on oaken legs at the town centre, is the only surviving example in Wales. It still possesses its ancient curfew bell and now houses a museum of local history and industry. Flannel weaving and lead mining flourished in the 19th century but after 1918 both industries declined and are now extinct. The present interests of the town are mainly agricultural but there is a foundry (established 1850), and a tannery for sheep and goatskin leathers (1908). There is a weekly market and a monthly fair and a cattle market was opened in 1955. Llanidloes was an active centre of Chartism, and for five days was in the hands of the rebels when the weavers rose in arms in 1839. The eastern slopes of Plynlimon, 10 mi. E., are now part of the Hafren state forest, covering several thousand acres.

LLANO ESTACADO (STAKED PLAINS), a portion of the high plains of the United States, covers an area of approximately 30,000 sq. mi. in western Texas and eastern New Mexico; the northern half is known as the Panhandle. The "break of the plains" bounds the area on the east; the Mescalero ridge overlooking the Pecos valley is the western margin; the Canadian river valley is at the northern edge; while in the south the region grades imperceptibly into the Edwards plateau. The present surface is composed of a mantle of silts, sands and gravels. Porosity of surface materials, levelness of terrain and semiaridity have combined to eliminate nearly all water erosion. The flatness of the surface is striking. Locally, small saucerlike depressions, varying in diameter from a few feet to almost a mile, and in depth from a few inches to several tens of feet, partially break the surface monotony. These hollows retain water for a short

time after rains and a few contain permanent though varying amounts of water.

Soils of high inherent fertility have evolved in the region, but their usefulness is restricted by meagre rainfall, high evaporation rates and periodic droughts. Blistering summers are succeeded by cool winters, strong winds are omnipresent, and weather extremes are commonplace. "Short grass," largely grama and buffalo grass, cloaks the uncultivated portions of the region.

Extensive grazing, dry-land farming of wheat and grain sorghums, localized irrigated cotton production, and the pumping of natural gas and petroleum are the principal economic pursuits of the area. Lubbock and Amarillo, Tex. (*q.v.*), are the most important cities of the region, but a less than salubrious climate, monotonous landscape and isolation combine to restrict population densities.

See also TEXAS: *Physical Features*; UNITED STATES (OF AMERICA): *Physiography: Interior Plains*. (A. H. Dr.)

LLANOS, Spanish American name for the vast plains or prairies of northern South America, extending from the Atlantic ocean to the Andes, and bounded by the coastal ranges in the north and by the Orinoco river (*q.v.*) and its Guaviare tributary on the south. The region, which covers about 125,000 sq.mi. in Venezuela and 100,000 sq.mi. in eastern Colombia, has a hot climate, supports little wild life and is sparsely populated.

The plains slope gently from a few hundred feet elevation at the base of the mountains toward the Orinoco and are broken here and there by low mesas. Many tributaries of the Orinoco drain the plains and flow in relatively straight courses. The largest of these are the Apure river (*q.v.*), the Arauca and the Meta, which rise in the far western part of the llanos.

The llanos are alternately flooded and dry in response to conditions of weather and terrain. The rainy season begins in May and reaches a peak between June and October when much of the area becomes flooded. The swollen rivers slowly recede during the dry season (December–March) and the land becomes parched and baked, the grass becoming brown and brittle for lack of moisture. Dense forests are confined to the stream courses and near the base of the mountains. The typical vegetation is tall, coarse grass with some dry, scrubby forests and scattered palms. Soils are chiefly infertile laterites, though fertile alluvial soils are fairly extensive.

Cattle were introduced into the llanos in 1548 and have been the mainstay since colonial days. The plains are Venezuela's most important stockbreeding region, accounting for two-thirds of the nation's cattle. Although plagues of insects make life difficult and herds must be driven to higher land during flood, several million head range widely in a region where fences are rare. Because of distance, much of the beef is shipped by air from such centres as San Fernando de Apure, the largest town in the central llanos, to Caracas. Irrigated agriculture has been developed in several places in the upper llanos since the eradication of malaria and the construction of large dams.

The *llanero*, the tough, hard-riding herdsman and skilled horseman of the plains, played an important role during the Venezuelan war of independence and has been an ardent supporter of successive revolutionary *caudillos*. See also VENEZUELA and COLOMBIA.

(D. R. D.)

LLANQUIHUE, province of southern Chile bordering the northern shores of Ancud gulf, bounded on the north by Osorno province, and extending from the Pacific to Argentina. Area 7,029 sq.mi. Pop. (1960) 165,959. The western half of Llanquihue is a rolling country of forests and pastoral and farm land; the east is a rough, volcano-studded, cordilleran landscape of deep glaciated valleys, lakes and virgin forest. It is noted for sports fishing. Chile's largest lake, Llanquihue (marginal to the mountains), and Lake Todos los Santos mark a scenic trans-Andean route to Argentina which draws sizable summer tourist traffic to Puerto Varas, Ensenada, Petrohué and Peulla. The provincial capital, Puerto Montt (*q.v.*), pop. (1960) 41,681, affords road access to the scenic southern coast line of the province and air and water service to island and mainland points extending from the Gulf of Ancud to Punta Arenas (*q.v.*). Rail, air, road and sea

communications are available to Santiago and Valparaíso. Summers are comfortable; winters are cool and very wet.

The province was formed in 1937 by dismembering Chiloé province. Less than 15% of its area is considered arable but about 50% of its gainfully employed people are in agriculture. Beef, dairy products, potatoes, wheat, fruit and wool are important. The increasing significance of sugar beets results from the construction of a beet sugar factory at Llanquihue in 1958. Lumbering, farm product processing, tourism, shipbuilding, fishing and the canning of seafood support large segments of the population. Since 1853 German pioneers and their descendants have played an important economic role. (J. T.)

LLANTWIT MAJOR (LLANILTUD FAWR), a small town in the Cowbridge rural district of Glamorgan, Wales, lies 1 mi. from the coast and 16 mi. W.S.W. of Cardiff by road. Pop. (1961) 4,243. Weapons and implements of the Bronze Age were discovered in a tumulus in the town. Castle Ditches, a triple line of earthworks, commands the entrance to the creek of Colhugh, once the port of Llantwit. At Caermead (1 mi. N.N.W.) lie the remains of a large Roman villa. Llantwit Major castle is now ruined.

The town derives its name from St. Illtyd or Iltutus (c. 500), a native of Brittany who established there a monastic college which became a famous seat of learning, associated with the Celtic saint movement in Wales. The monastery later became a cell of Tewkesbury abbey and was finally destroyed at the Dissolution, only the gatehouse and dovehouse remaining. The present church of St. Illtyd, dating from the 12th and 15th centuries, is divided into the old (western) part, probably the parish church, which houses Celtic crosses, effigies, etc., and the new, probably the monks' chapel, which has a Jesse niche and is now used as the parish church. The ruined chantry was finally destroyed by an air raid in 1940. The town hall is 15th century. Llantwit lies in a fertile district; its people depend to some extent upon agriculture, but most of them are employed at a nearby Royal Air Force station. (W. A. L. S.; P. Cr.)

LLEWELYN, the name of two Welsh princes.

LLEWELYN AP IORWERTH (d. 1240), known as the Great, was the most outstanding ruler to appear in Wales before the Edwardian conquest. A patrimony in Gwynedd having been denied him as a child, he was brought up by his mother's family in the neighbouring principality of Powys. Returning to Gwynedd about 1190, he had eliminated rival kinsmen, restored the unity of Gwynedd, and brought the greater part of north Wales under his sole rule by 1202. King John's acquiescence was secured and Llewelyn married John's illegitimate daughter, Joan. Llewelyn's subsequent attempts to dominate other Welsh states alarmed the king, who invaded Wales in 1211 and brought temporary disaster to the prince's ambitions. John's political embarrassments, culminating in the Magna Carta crisis in 1215, gave Llewelyn an ideal opportunity to reassert his supremacy and in 1218 he wrested very favourable terms at Worcester from the regency that followed John's death. The treaty recognized the prince's mastery over territories lying roughly west of a line from Carmarthen to Montgomery, including control of those two strongholds. Checked only once after Worcester, by William Marshal, earl of Pembroke, in 1223, Llewelyn was obliged, to his ultimate advantage, to move back to the more restricted Cardigan-Builth boundary. Henceforth Llewelyn concentrated on preserving this position, striving to secure the interests of his dynasty through marriages arranged for David, his younger son, by his marriage with Joan, and four of his daughters with the Anglo-Norman aristocracy in south Wales. He also explored every avenue whereby David should be recognized as sole heir to a feudal principality of Wales. This was a new concept which was realized through Llewelyn's insistence on homage from the other Welsh princes, although this did not mean their withdrawal from direct allegiance to the crown. When he died in April 1240 at the Cistercian abbey of Aberconwy, where he was buried, the chronicler described him as prince of Wales, which he was in fact, if not in law.

LLEWELYN AP GRUFFYDD (d. 1282), grandson of Llewelyn the Great, and the only Welsh ruler to be officially recognized as

prince of Wales, was given a share of Snowdonia by the treaty of Woodstock in 1247 when the kingdom of Gwynedd collapsed after the death in 1246 of David II (see DAVID). Llewelyn, establishing an ascendancy over his brothers by 1254, and taking full advantage of renewed civil disturbance in England, proclaimed himself prince of Wales and received the homage of the Welsh princes (1258). The defeat of the prince's ally, Simon de Montfort, and the cessation of civil war in England still left Llewelyn strong enough to be offered most advantageous terms in the Montgomery settlement (1267). In addition to confirmation of territorial conquests, which included several marcher lordships in mid-Wales, Henry III conceded to Llewelyn the homage of native lords, permitting Llewelyn alone to do homage and fealty for the entire principality of Wales. With the accession of Edward I in 1272, Llewelyn, apparently unaware of how things had now changed in England, defied the new king and brought upon himself a signal humiliation in the war of 1277. When hostilities were renewed in 1282 the prince was mortally wounded in a skirmish near Builth on Dec. 11, and his death marked the end of Welsh political independence. Shortly before Llewelyn's death his wife, Eleanor de Montfort, gave birth to a daughter, Gwenllïan, who spent the remainder of her life in an English nunnery. See also WALES: *History*. (T. J. P.)

LLIVIA, a town and enclave of Spanish territory in the French *département* of Pyrénées Orientales, a part of the ancient district of Cerdagne or Cerdania. Llivia is included in the Spanish province of Gerona. Pop. (1960) 755. The Cerdagne comprises the upper basin of the Segre on the southern flank of the Spanish Pyrenees. A faulted basin at about 3,300 ft., formerly a lake floor, it is surrounded by such high mountains as Carlitè (9,583 ft.), Campeardas (9,560 ft.) and Puigmal (4,540 ft.). The irrigated meadows of the Cerdagne are important for winter pasturage—the Canal de Puigmal was constructed in 1310. The Roman Julia Livia, the town was capital of the Cerdagne until the 11th century. In 1659, by the treaty of the Pyrenees, 33 Cerdagne villages were ceded to France and the political enclave was created.

LLOYD, GEORGE AMBROSE LLOYD, 1ST BARON (1879–1941), British statesman and colonial administrator, was born at Olton hall, Warwickshire, on Sept. 19, 1879. He was educated at Eton and Trinity college, Cambridge. After traveling widely in Asia and north Africa Lloyd was appointed attaché to the British embassy at Constantinople in 1905. During World War I he saw service in Russia and the middle east and was with the sheriff of Mecca's forces in the Hejaz and was decorated in 1917. He was Conservative member of parliament for West Staffordshire (1910–18) and for Eastbourne (1924–25). He was governor of Bombay from 1918 to 1923 and in May 1925 was appointed high commissioner of Egypt and the Sudan, where he was notable for refusing concessions to nationalist agitation. On this account he was recalled by the Labour government in 1929. In the 1930s he was one of Winston Churchill's staunchest supporters. In 1940 he entered Churchill's cabinet as colonial secretary and was appointed leader of the house of lords shortly before his death in London on Feb. 4, 1941.

(H. G. N.)

LLOYD, HENRY DEMAREST (1847–1903), U.S. author and social reformer, was born in New York city, May 1, 1847. After graduating from Columbia college and Columbia law school, he spent three years practising law and engaging in reform activities. In 1872 he left New York to accept a position on the staff of the *Chicago Tribune*. He served on that paper for the next 13 years at its literary, financial and editorial desks and then retired to devote full time to public affairs.

During the remainder of his life, Lloyd was an outstanding advocate of the rights of labour and a severe critic of the abuses by private monopoly. His most publicized work was *Wealth Against Commonwealth* (1894), a carefully documented study of the methods used by the Standard Oil company in ridding itself of its competitors. In the late 1890s Lloyd made several trips to Europe and New Zealand to study experiments in the fields of voluntary co-operation, public ownership and social legislation. On returning home he wrote a series of books on these experiments and urged

the adoption of a number of them in the United States. In his last years he regarded himself as a socialist and was on the verge of joining the Socialist party when, in the midst of a traction fight in Chicago, he died (Sept. 28, 1903). His life and writings profoundly affected the social reform movement of the late 19th and early 20th centuries.

See Caro Lloyd, *Henry Demarest Lloyd, 1847–1903*, 2 vol. (1912). (H. W. L.)

LLOYD, MARIE (MATILDA ALICE VICTORIA WOOD) (1870–1922), English music-hall artist, who made her name in the particular kind of London or cockney low comedy which attained great popularity in the 19th century, was born on Feb. 12, 1870, the daughter of John and Matilda Wood. She first appeared at the Eagle music hall in 1885 under the stage name of Bella Delmore. Six weeks later she adopted the stage name of Marie Lloyd, which she retained. She was responsible for a series of music-hall entertainments, songs, sketches, etc., which placed her in the front rank among artistes of her day. She introduced to the British public a series of studies in cockney humour, e.g., "Everything in the garden's lovely," "Oh, Mr. Porter" and "One of the Ruins that Cromwell knocked about a bit." She was married to Percy Courtney; to Alec Hurley, a singer of coster songs (d. 1913); and to Bernard Dillon, a jockey. She died in London on Oct. 7, 1922.

(E. I. J.)

LLOYD, WILLIAM (1627–1717), English bishop, politician and writer, was one of the seven bishops arrested in 1688 for refusing to have the Declaration of Indulgence read in their dioceses. He was born at Tilehurst, Berkshire, on Aug. 18, 1627, and educated at Oriel and Jesus colleges, Oxford. He was successively bishop of St. Asaph (1680), Lichfield and Coventry (1692) and Worcester (1699). His anti-Romanist outlook made Lloyd a bitter opponent of James II, and he strongly supported the Revolution. His chief publication was *An Historical Account of Church Government as It Was in Great Britain and Ireland When They First Received the Christian Religion* (1684). He died at Hartlebury castle, Worcestershire, on Aug. 30, 1717.

See A. Tindal Hart, *William Lloyd, 1627–1717* (1952). (G. Hu)

LLOYD GEORGE OF DWYFOR, DAVID LLOYD GEORGE, 1ST EARL (1863–1945), radical reformer, leader of Britain in World War I, and one of the most brilliant statesmen in British history, was born in Manchester on Jan. 17, 1863. His father was of Welsh yeoman extraction from Pembrokeshire and had become headmaster of an elementary school in Manchester. His mother was the daughter of David Lloyd, a Baptist minister. His father died in June 1864, leaving Mrs. George in poverty. She moved to Llanystumdwy in Caernarvonshire where her brother Richard was a shoemaker and pastor of the Campbellite Baptists in that area. He supported her and her children, and it was from him that David Lloyd George imbibed many of his formative beliefs. It was thanks to his uncle that he was able to embark at the age of 14 on the career of a solicitor, and became articled (1879) to a firm at Portmadoc, passing his final examination in 1884. The atmosphere in which he was brought up was one of intense Liberalism combined with Welsh nationalist enthusiasm. In Wales, as in Ireland, an anglicized and Anglican Tory "ascendancy" class of landed gentry dominated a Celtic people of different race and religion. The cause of the Liberal party, the Welsh nation and Nonconformity were inseparable and Lloyd George made his name by a successful battle in the courts to establish the right of Nonconformists to burial in the churchyard of their parish. By a curious irony, he who came to be the standard-bearer of the oppressed religious sects had lost his faith even as a boy. But the habits and way of thought, the emotions, the eloquence and the biblical fervour of Welsh Nonconformity remained with him to the end of his days. As a young man he had the romantic good looks which ensured success with women. After numerous love affairs he married in 1888 Margaret Owen, the daughter of a Methodist farmer near Criccieth. She bore him five children, two sons and three daughters. It cannot be described as a happy marriage. Lloyd George was incapable of fidelity and his affairs with other women were notorious throughout his life. His wife stood by him on many critical occasions but in the end his behaviour was

too much for even her long-suffering tolerance.

Member of Parliament.—In 1890 a by-election took place at Caernarvon Boroughs. Lloyd George was the Liberal candidate and after a recount he was declared victor by 18 votes. He retained the seat for 55 years. He soon made a name for himself in the house of commons by his audacity, his almost poetical command of language, his extraordinary charm, his mordant wit and his mastery of the art of debate. During the ten years of Liberal opposition which followed the election of 1895 he established himself as a leading figure in the radical wing of the party. He bitterly opposed the South African War and one of his most famous exploits was his attempt in 1901 to penetrate that stronghold of Conservative imperialism, Joseph Chamberlain's Birmingham. He had frequently accused Chamberlain of personal profiteering from the war—a wholly unwarranted charge. It was not surprising that he was nearly lynched. He had to leave the town hall disguised as a policeman. With the arrival of peace Lloyd George fiercely attacked Balfour's Education act (1902), and worked up a great agitation in Wales against rate-aided grants to church schools. This period saw him at the height of his reputation as the leader of Welsh nationalism. Cabinet office somewhat reduced his fervour in this field and, although he succeeded in achieving one of the objects of the movement, the disestablishment of the Anglican church in Wales, which finally, after many vicissitudes, became law in 1920, he ceased to press the case for federal home rule. With the passage of time his nationalism became cultural rather than political.

A. J. Balfour resigned in Dec. 1905 and Sir Henry Campbell-Bannerman formed a Liberal administration which was confirmed in office a few weeks later by a crushing electoral victory. Lloyd George walked straight into the cabinet as president of the board of trade. He was responsible for important legislation—the Merchant Shipping act (1906), which laid down minimum conditions of decent living for seamen; the Patents and Designs act (1907), which stopped foreign exploitation of loopholes in the British law; and the Port of London act (1908), which set up the Port of London authority. He also earned a high reputation by his patient work in settling strikes. He suffered a cruel bereavement in Nov. 1907: his second child and eldest daughter, Mair, to whom he was devoted, died of appendicitis at the age of 17. For a time he plumbed the depths of despair and for years afterward the sight of her portrait could plunge him into tears.

CHANCELLOR OF THE EXCHEQUER

Campbell-Bannerman's health broke down in 1908. He was succeeded as prime minister by the chancellor of the exchequer, Herbert Henry Asquith, who promptly appointed Lloyd George to take his own place. This was a notable promotion and made him, if not second man in the cabinet, at least a very strong competitor for the premiership after Asquith. By this time the Liberal party's fortunes were beginning to languish. The house of lords had blocked much of their social reform legislation, and the radical wing was beginning to show impatience at the danger of their thunder being stolen by the nascent Labour party unless the deadlock could be broken. At the same time the demand for more battleships to match the German naval program threatened the finances available for social reform. It was to meet these difficulties that Lloyd George framed the famous "people's budget" of 1909. New methods of raising money, by taxes upon unearned increment on the sale of land and on land values, by higher death duties and by a super tax on incomes above £3,000, solved the problem of means. Moreover it seemed for a time that the house of lords' veto on progressive legislation would be bypassed, since the custom, though not the law, of the constitution forbade the upper house from interfering with the budget. In fact, however, the Conservative majority in the house of lords decided to reject it. It is sometimes said that Lloyd George deliberately trapped them, but there is no evidence to support this view. His conciliatory method of presenting the budget suggests on the contrary that he never expected such a foolish reaction. The consequences of this rejection were two general elections, a major constitutional crisis and the ultimate passage of the Parliament act of 1911,

which severely curtailed the powers of the upper house. The principal burden of all this fell upon Asquith, but Lloyd George, ably seconded by Winston Churchill, gave him vigorous support in a series of notable philippics against the aristocracy and the rich. The most famous of all was his speech at Limehouse where he denounced the rapacity of the landlord class, particularly the dukes, in unforgettable language. Intense passion was aroused, King Edward VII expressed strong disapprobation, and the duke of Beaufort declared that there was nothing that he would like to see so much as "Winston Churchill and Lloyd George in the middle of 20 couple of dog-hounds." Lloyd George was one of the greatest platform orators of his time—perhaps of any time—and he rose to his highest during the budget campaign. At Caernarvon he uttered his most splendid peroration. He described how as a child he never attempted to gather sticks for firewood except after some great storm:

We are in for rough weather; we may even be in for a winter of storms which will rock the forest, break many a withered branch, and leave many a rotten tree torn up by the roots. But when the weather clears, you may depend upon it there will be something brought within the reach of the people that will give warmth and glow to their gray lives, something that will help to dispel the hunger, the despair, the oppression and the wrong which now chill so many of their hearts.

Yet in spite of his, at times, extremist language, Lloyd George was not averse to compromise. During the summer of 1910 he was a leader of those—Balfour, Churchill and F. E. Smith (later Lord Birkenhead) among others—who favoured a coalition with the Conservatives, based upon agreed solutions of the problems of Irish home rule, tariffs and conscription. Nothing came of these negotiations, although they were prophetic of subsequent events.

In 1913 he faced one of the gravest personal crises in his career. In April 1912, along with Rufus Isaacs (later marquess of Reading), the attorney general, he had purchased shares in the American Marconi company through Isaacs' brother, Godfrey, who was managing director, at a preferential rate well below that available to the general public. The American Marconi company was legally independent of the British concern, but the fortunes of the two companies were closely connected, and the latter's shares had recently boomed as a result of the government's decision to accept its proposal to construct a chain of radio stations throughout the empire. Rumours of corruption were widespread and were only stilled by a libel action brought by Lloyd George and Isaacs against a French newspaper. But unluckily they had already denied, in somewhat ambiguous language, any transactions in the shares of "the Marconi company," a denial which technically referred only to the British company but was generally assumed to cover the American as well. The select committee of the house of commons appointed to investigate the matter revealed the facts and, although by a party majority it acquitted the ministers of blame, Lloyd George's reputation for integrity was damaged.

Social Reform and the Outbreak of War.—Lloyd George's major achievement during the years immediately before the war was in the field of social insurance. Old-age pensions had already been introduced, though on a noncontributory basis, by Asquith in 1908. Inspired by a visit to Germany (1908), where he studied the Bismarckian scheme of compulsory contributory insurance benefits, Lloyd George decided to introduce health and unemployment insurance on a similar basis in Britain. This he did in the National Insurance act of 1911. The measure inspired bitter opposition. It was unpopular with the working class who were not convinced by Lloyd George's own slogan "ninepence for fourpence," the difference in these two figures being the employer's and the state's contribution. Naturally the employers were against it, and the doctors were up in arms at a threat to their private practices. Lloyd George was undeterred, and piloted his measure through parliament with great skill and determination. He thus laid the foundations of the modern welfare state and, if he had done nothing else, would deserve fame for that achievement.

Much of the government's time during these years was occupied by the Irish question. Lloyd George was not in the forefront here. Nor was he normally much concerned with the grave issues of foreign policy which increasingly dominated the minds of his

leading colleagues. On the whole he inclined to the "little Englander" side of the party. It was, therefore, something of a sensation when, in July 1911, after careful consultation with Asquith and Sir Edward Grey, he chose the occasion of the chancellor of the exchequer's traditional Mansion house speech to utter a formidable warning to Germany as to the limits of British endurance over the Agadir crisis. When the question of intervention on the side of France convulsed the cabinet in late July and early August 1914 he seemed at first to incline to the isolationist section. For a brief moment he contemplated retirement. But the tide of events swept him to the other side. As chancellor he plunged into the financial problems posed by the war. Less than two months after its outbreak he made one of his most eloquent speeches; referring to the comfortable existence in "a sheltered valley" led by most of his compatriots, he urged them to remember "the everlasting things that matter for a nation—the great peaks we had forgotten, of Honour, Duty, Patriotism, and, clad in glittering white, the great pinnacle of Sacrifice pointing like a rugged finger to Heaven."

Minister of Munitions and Secretary of State for War.—Throughout the remainder of 1914 and the early months of 1915, Lloyd George was a vigorous advocate of increased munitions production. Here he came into sharp conflict with Earl Kitchener, for he pressed again and again the case for removing the whole field of supply from the war office. The resignation of Admiral Fisher in 1915 forced Asquith to reconstruct the government on a coalition basis and admit the Conservatives. In the new administration Lloyd George became minister of munitions. In this capacity he made one of the most notable contributions to the victory of the Allies. His methods were unorthodox and shocked the civil service, but his energy was immense, and it is to be doubted whether any other person could have produced the tremendous expansion needed. He imported able assistants from the world of big business, and he used his persuasive eloquence to induce the co-operation of organized labour. When in the summer of 1916 the great battle of the Somme began, supplies were adequate, though not lavish. On war strategy Lloyd George acquired definite views at an early stage. He was an "easterner," one of those who doubted the possibility of breaking through on the western front and advocated instead a flank attack from the near east. He was thus at loggerheads, almost from the beginning, with the view of the official military hierarchy, cogently pressed by Sir Douglas Haig and Sir William Robertson, that the war could only be won in the west. On June 5, 1916, Kitchener was drowned on his way to Russia. A last-minute accident—acute developments in the Irish situation—alone prevented Lloyd George from traveling with him and suffering the same fate. After some hesitation Asquith appointed him to the vacant position at the war office.

Lloyd George held the post for five months. Robertson as chief of the imperial general staff possessed, under a concordat arranged at the end of 1915, nearly all the really important powers of the war minister. Lloyd George chafed under these restrictions, the more so since he profoundly disagreed with Robertson on the vital issues of strategy. Thus frustrated he began to survey the whole direction of the war with increasing skepticism, and he did not conceal his doubts from his friends, Sir Edward Carson, Andrew Bonar Law, and above all Sir William Maxwell Aitken (afterward Lord Beaverbrook), who played an important role as an intermediary in the crisis that ensued. By the end of November Lloyd George and his friends had become convinced that Asquith should delegate the day-to-day running of the war to a small committee whose chairman should be Lloyd George. There was undoubtedly widespread uneasiness at Asquith's conduct of affairs, particularly in the Conservative party. A series of maneuvers, too complicated to describe here, resulted in Asquith's resignation on Dec. 5 and his replacement on Dec. 7 by Lloyd George. He was supported by the leading Conservatives, Bonar Law becoming chancellor of the exchequer, leader of the house and second in command of the government, and Balfour becoming foreign secretary. But the most prominent Liberal ministers, Reginald McKenna, Grey, Lord Crewe and Sir Herbert (later Viscount) Samuel, resigned with Asquith, and, although about half the rank

and file of the party supported the new government, Lloyd George was never forgiven by the old guard of his party for having, as it seemed to them, jockeyed Asquith out of office.

PRIME MINISTER

Lloyd George was now 54 and at the height of his powers. His energy, eloquence and ability had already made him the leading statesman of the day, and his accession to the premiership was highly popular in the country generally. A sense of renewed vigour, of "push and go," was given to the whole war effort. Lloyd George immediately substituted a small war cabinet of 5, which was to be in constant session, for the unwieldy body of 23 which had hitherto conducted affairs. He instituted a cabinet secretariat headed by Sir Maurice (later Lord) Hankey, and for the first time decisions were properly recorded and minutes kept. The result of these changes at the top was a general speeding up of decisions and the disappearance of the procrastination which from time to time seemed to have marred the activities of the previous government. Among Lloyd George's earliest actions was his resolve to associate organized labour with the government. Another early and important decision was to secure the closer co-operation of the dominion prime ministers and other leaders in the empire by the creation of an imperial war cabinet and the holding of regular imperial war conferences.

One of Lloyd George's most notable achievements was in combating the submarine menace which in the early months of 1917 threatened to starve Britain into submission. Not only did he force the adoption of the convoy system upon a very reluctant admiralty, but he also succeeded in greatly increasing the construction of merchant shipping to replace losses—his instrument being a great shipowner, Sir Joseph (afterward Lord) Maclay whom he appointed as director of shipping. Another acute problem which arose from the submarine threat was the food shortage. Drastic action had to be taken to step up agricultural production, and eventually a system of food rationing had to be introduced (1918). In all these matters Lloyd George was at his best, contemptuous of red tape and official obstruction, determined to take action and to make his will prevail.

It was in the field of grand strategy that he was least successful. By the time of his accession it was too late, even if it ever had been possible, to launch an effective "eastern" strategy. But Lloyd George remained profoundly skeptical of the ability of the British high command to conduct even a "western" strategy successfully. Without warning Haig or Robertson in advance he confronted them at the Calais conference of Feb. 1917 with a plan concerted with Aristide Briand, the French prime minister, to place the British army under French command for Gen. Robert Nivelle's forthcoming offensive. Although the plan was somewhat modified as a result of protests from Haig and Robertson, the two generals deeply distrusted Lloyd George from that moment onward. The Nivelle offensive was a total failure and Lloyd George was, as a result, on slightly shaky ground when he endeavoured to resist Haig's proposals for a major British campaign in Flanders in the summer. After much hesitation he gave way, and on July 31, 1917, the ill-fated Passchendaele offensive began. Although there can be argument as to whether on balance the German or the British army was the more devastated at the end of the campaign and, although the offensive may have forestalled a possible German attack on the French, Passchendaele achieved none of its main objectives. In November mud and rain brought it to a final halt. Lloyd George was now convinced of the incompetence of Haig and Robertson.

He still dared not take action against them openly. Instead he began what Sir Winston Churchill calls "a series of extremely laborious and mystifying maneuvers" with the object of creating a unified command whose generalissimo would be someone other than Haig. In Feb. 1918 Robertson offered his resignation, which Lloyd George accepted. It was tantamount to dismissal. Haig, however, remained as commander in chief while Sir Henry Wilson was promoted to fill Robertson's place. Such was Lloyd George's distrust of Haig that during the winter of 1917-18 he had deliberately kept him short of troops for fear that he might renew the

attack. The result was that Ludendorff's March offensive broke the British line, came near to splitting the French and British armies, and threatened to drive the latter into the sea. The emergency caused a unified command under Marshal Foch to be established (April) and by May the situation became stabilized. Out of these events arose the famous Maurice debate. Maj. Gen. Sir Frederick Maurice, who was in the war office, published a letter claiming that Lloyd George had given incorrect figures in reply to a question about manpower on the western front. Lloyd George made a brilliant speech at the subsequent debate, though later evidence shows that Maurice was undoubtedly right. But the Asquithian Liberals pressed the matter to a division and were heavily beaten.

The tide now turned in the west. Haig launched a series of successful attacks upon an exhausted German army that had shot its last bolt. The Armistice of Nov. 1918 faced Lloyd George with a dilemma. Should he allow a return to peacetime party politics or continue the coalition? There was little doubt of the answer. Bonar Law was willing to co-operate. A somewhat perfunctory offer to include Asquith was declined. The ensuing election in December gave the coalitionists an overwhelming victory. Those who followed Asquith at the Maurice debate were not granted the "coupon," the joint letter from Lloyd George and Bonar Law which certified the candidate as a coalitionist. Nearly all, Asquith included, lost their seats. The rift in the Liberal party became wider than ever and Lloyd George was now largely dependent on Conservative support. It is sometimes said that he handicapped himself at the peace conference by having pandered to ill-informed public demand for a Carthaginian peace during the "coupon" election. Examination of his speeches does not bear out the charge. He never ceased to utter cautionary warnings about Germany's capacity to pay, although he did not fail to emphasize the Germans' moral obligation to pay all they could.

Postwar Policy.—As one of the three great statesmen at Versailles, Lloyd George must bear a major responsibility for the peace settlement. He pursued a middle course between that of Georges Clemenceau, who was determined to keep Germany as weak as possible in the interest of France, and President Wilson, who aimed at a peace based upon international justice, self-determination and the League of Nations. But, throughout, Lloyd George was under strong pressure at home to pursue the more draconian policy. Lord Northcliffe, one of the few press proprietors whom he had failed to placate, was foremost in advocating harsh terms. It is to Lloyd George's credit that the final settlement was not far worse, and many of the bad features of Versailles arose from later developments which he could not have foreseen. The treaty was well-received in Britain, and in Aug. 1919 the king conferred on him the Order of Merit.

Meanwhile at home Lloyd George had reconstructed his cabinet, restoring it to its peacetime size. Bonar Law remained leader of the house, but gave up the exchequer to Austen Chamberlain. Lord Curzon had the foreign office, Churchill the war office, and F. E. Smith, the lord chancellorship. There was much industrial discontent, and the difficulties of adjusting Britain's economy from war to peace were formidable. Lloyd George played an important part once again as arbitrator and conciliator in numerous strikes.

A major domestic problem was Ireland where the Sinn Fein refused to recognize the British parliament and from 1919 to 1920 a civil war of massacre and reprisal raged. The temporary retirement of Bonar Law in March 1921 indirectly weakened Lloyd George's position, for the former's successor as leader of the Conservative party, Austen Chamberlain, was less in touch with the rank and file of the party and less capable of stating disagreeable home truths to the prime minister. In the summer of 1921 Lloyd George, with full agreement of his Conservative colleagues, reversed the policy of repression in Ireland and initiated the negotiations with Arthur Griffith and Michael Collins that culminated in the Irish treaty of Dec. 1921. The more rigid Tories never forgave this "surrender," as they deemed it. In 1922 Lloyd George ran into further trouble over the so-called honours scandal when accusations were made in both houses of parliament that

peerages and other honours were being regularly sold for large sums of money. There seems to have been some truth in the allegation. Lloyd George lacked the funds to finance a party machine of his own, the Liberal organization being in Asquith's hands. It is certain that he raised a very large sum, and probable that he was not overscrupulous about the character of the contributors. Tory discontent was rife when from a wholly unexpected quarter a crisis occurred that drove Lloyd George from power forever. This was the Chanak incident (*see TURKEY: History*), when it seemed to critics that the reckless foreign policy of the government had led Britain to the verge of an unnecessary war with the Turkish dictator, Mustafa Kemal Atatürk. These criticisms were not warranted. Lloyd George's firm line in fact preserved peace and was not the act of a warmonger. But when the Conservative leaders decided to appeal to the country on a coalition basis once again, a party revolt ensued. Bonar Law returned to the political scene and on Oct. 19 a 2 to 1 majority of Conservative M.P.s endorsed his and Stanley Baldwin's plea to fight as an independent party. Lloyd George at once resigned, and was succeeded by Bonar Law who won an easy victory at the general election that followed.

POLITICAL ECLIPSE

The long twilight of Lloyd George's career was a melancholy anticlimax, and can be but briefly told here. The feud with the Asquithians was never healed. There was a temporary *rapprochement* for the 1923 election, and the united party won 158 seats, but in 1924 the number slumped to 40. In 1926 Lloyd George expressed opinions on the general strike which conflicted with those of Asquith (now Lord Oxford and Asquith) and the latter resigned his leadership. Lloyd George was elected in his place but his personal control over the immense political fund that he had acquired as prime minister caused endless discontent, for he firmly declined to hand it over to the party whips and doled it out as he saw fit. In the election of 1929 the party's fortunes slightly revived, numbers rising to 59, but the economic crisis of 1931 saw the end of Lloyd George's leadership. He was ill at the time and subsequently denounced the decision of Samuel and Sir John Simon to join the national government. Thereafter he was a lonely political figure, and, although there was from time to time talk of his joining the government, nothing came of it. He devoted himself to writing his *War Memoirs* (1933-36) and *The Truth About the Peace Treaties* (1938). Of vast length, yet supremely readable and interspersed with many brilliant pen portraits, these volumes are an exercise in the forensic rather than the historian's art. He seldom admits error and the endless diatribes against his opponents carry little conviction. His memoirs lack the Gibbonian majesty and the genuine detachment of Churchill's. In 1936 he visited Germany and met Hitler. Like many others he was temporarily taken in by him, but he soon saw his error, and in 1938 and 1939 he was a leading opponent of appeasement. In 1940 Churchill invited him to join his war cabinet, but Lloyd George, who had become something of a defeatist, declined, ostensibly on grounds of age and health. On Jan. 1, 1945, he was elevated to the peerage as Earl Lloyd George of Dwyfor. He died on March 26, 1945.

Lloyd George's first wife died in 1941 and in 1943 he married Frances Louise Stevenson, who had been his private secretary since 1913. Of the four surviving children of his first marriage, two entered politics. Gwilym (1894-1967) entered parliament as a Liberal in 1922 and as Liberal and Conservative member for Newcastle upon Tyne was home secretary and minister for Welsh affairs from 1954 to 1957, when he was created Viscount Tenby of Bulford. Megan (1902-1966) was a Liberal member of parliament from 1929 to 1951 and deputy leader of the party (1949-51), but subsequently joined the Labour party and became Labour M.P. for Carmarthen in 1957.

CHARACTER AND ACHIEVEMENTS

"What is this glittering whirl at the centre of our public life?" asked one of Lloyd George's many critics. It is not an easy question to answer. His personality is something of an enigma to the historian. It is easy to list his qualities: his eloquence; his

extraordinary charm and persuasiveness; his sense of wit and fun; his capacity to see to the heart of problems whose complexity baffled lesser men; his profound sympathy with oppressed classes and races; his genuine hatred of those who abused power, whether that power was based on wealth or caste or military might. But there was an obverse side to these virtues: his love of devious methods; his remarkable, albeit temporary, gullibility in the face of Hitler and the Nazis; his carelessness and want of discretion—some would use severer words—over appointments and honours; his defeatism in World War II, which contrasted so sadly with his earlier courage.

The truth is that Lloyd George, for all his greatness, aroused in many people a profound sense of mistrust. "England, a country subject to fogs and possessing a powerful middle class, needs grave statesmen," wrote Disraeli. Lloyd George, like Disraeli himself, was never a grave statesman. Like Disraeli, too, he was not even English, and it was in the English middle class, represented in politics by Stanley Baldwin and Neville Chamberlain, that he inspired the acutest misgivings. They were both determined to exclude him from office, and it would be wrong to ascribe his long years in the political wilderness solely to the declining fortunes of the Liberal party. It is perhaps significant of his defects that Lloyd George, though possessing a host of acquaintances and a number of sycophants, never had a really intimate friend. Winston Churchill was the only political personage who habitually addressed him in letters as "My dear David." There was in him a streak of ruthlessness which left little room for the cultivation of personal friendship. Lord Beaverbrook, who knew him well, wrote: "Once he is estranged there is none of that lingering afterglow which makes us still cherish memory and hesitate to strike the sometime companion."

For these and other reasons he was never able to recover the position he had lost in 1922. It was one of the tragedies of the interwar years that in an era not notable for political talent the one man of genius in politics, who might have found some solution for Britain's economic malaise, should have been condemned to remain an impotent spectator on the sidelines. But his earlier achievements make his place in history secure. He laid the foundations of the welfare state. He led Britain to victory in what seemed then the greatest of all wars. For 16 years from 1906 to 1922 he dominated the political scene. In the words of Churchill addressing the house of commons after Lloyd George's death: "When the English history of the first quarter of the twentieth century is written it will be found that the greater part of our fortunes in peace and in war were shaped by this one man." See LIBERAL PARTY (BRITISH); see also references under "Lloyd George of Dwyfor, David Lloyd George" in the Index.

LLOYD'S, an international insurance market in London and the world centre of shipping intelligence, is known throughout the world as "Lloyd's of London." Its origins date from the 17th century. The corporation of Lloyd's is the governing body of the market but does not itself transact insurance business: this is done by individuals, known as underwriting members of Lloyd's, who accept insurance for their own account and risk and in competition with each other.

Only underwriting members are eligible to accept insurance at Lloyd's. The corporation of Lloyd's lays down very strict financial rules and other regulations for membership designed to insure the maximum security behind Lloyd's policies. Candidates for membership must be supported by six existing members and are elected by ballot only after they have proved to the satisfaction of the committee of Lloyd's that their resources are sufficient to meet any liabilities likely to be incurred. Underwriting members must make deposits in cash or approved securities with the corporation of a minimum of £15,000 where marine and nonmarine business

is to be transacted. They must also pay their annual premium income into trust funds from which only amounts for the payment of claims, expenses and ascertained profits may be released; submit to a searching annual audit; and carry on their underwriting with unlimited liability.

There were in the mid-1960s approximately 5,500 underwriting members of Lloyd's, not all of whom were actively engaged in insurance. They were formed into about 300 syndicates comprising from a few to several hundred members. These syndicates are represented at Lloyd's by underwriting agents and it is they who accept insurance business on behalf of the members of their syndicates. This syndicate system was developed to handle the greatly increased insured values of the 20th century and to enable underwriters to give much larger insurance cover than they would be able to do if they accepted risks on behalf of themselves alone. Members of syndicates not underwriting personally are known as "names" but are still responsible with unlimited liability for the business transacted for them by their underwriting agents.

Insurance may be placed with Lloyd's underwriters only through Lloyd's brokers, of which there were more than 200 firms in the early 1960s. Brokers are the representatives of the insured and it is their function to try to obtain from underwriters the most favourable terms possible. When placing insurance, the broker prepares what is known as a "slip," a folded sheet of paper, on which are written the principal facts of the risk to be covered. He takes this slip from underwriter to underwriter in the underwriting room at Lloyd's to obtain competitive quotes of premium. When the broker has reached agreement with an underwriter on a suitable rate of premium, the underwriter writes his initials on the slip and the amount of the risk he is prepared to accept; if the insured value is very large an underwriter may be prepared to accept only a portion of the risk on behalf of his syndicate. In this case the broker must approach other underwriters and persuade them also to accept percentages at the same rate of premium until he has obtained the required cover.

By this system an insurance risk is spread over a number of individuals and should a claim be made each underwriter is responsible only for his portion of it. This practice enables extremely heavy losses to be borne without the dire repercussions that might otherwise be felt.

Lloyd's Coffeehouse.—Lloyd's has an interesting history. In 1688 Edward Lloyd kept a coffeehouse in Tower street. There, as in other similar houses, merchants, bankers and seafarers assembled to drink coffee and transact business informally. The coffeehouse was also the popular meeting place for underwriters—those who would accept insurance on ships for the payment of a premium—and over the years it became recognized by seekers of insurance cover as the most likely place where a number of underwriters could be found.

From this informal beginning Lloyd's gradually grew in repute and influence. It had been the practice of Edward Lloyd to supply his customers with shipping information obtained from the docks by runners and from other sources, and in 1696 he published for a short period *Lloyd's News*, giving details of shipping movements and other matters of interest; this was the forerunner of *Lloyd's List*, first published in 1734.

Lloyd died in 1713 but his coffeehouse, then situated in Lombard street, retained his name and survived two and a half centuries of subsequent development. In 1774 under the guidance of John Julius Angerstein, perhaps the most outstanding personality who has appeared in its history, Lloyd's moved to the royal exchange. It remained there for more than a century and a half during a tenancy broken only by the period of rebuilding after a fire in 1838. In 1928 a new building was opened on the site of the East India house in Leadenhall street, and in 1952 the foundation stone was laid of another new building in Lime street, which was opened in 1957.

The outbreak of war with France in 1793 led to a period of remarkable expansion during which Lloyd's advanced in wealth and importance, although the underwriters were at times subjected to losses that strained their resources. In the year 1794-95, for example, one underwriter, Robert Sheddon, paid out £190,000

to satisfy claims. During 1793–1815 Lloyd's exerted a salutary influence on the admiralty and the direction of naval operations in relation to seaborne trade, especially in regard to the use of convoys. At a time when the state made no provision for war victims, Lloyd's inaugurated many subscriptions for that purpose, culminating in the establishment in 1803 of the patriotic fund, which is still in operation. Gifts of silver plate were made to Lord Nelson and to the captains at Trafalgar. A portion of the Nelson plate and a Trafalgar cup, designed by John Flaxman, later came into the possession of Lloyd's and form part of the society's Nelson collection.

In 1811 under the influence of its chairman, Joseph Marryat, M.P., father of the novelist Frederick Marryat, and himself a man of unusual ability, Lloyd's prepared the way for incorporation by the curious expedient of inducing the subscribers to sign a trust deed vesting the corporate funds in the committee of treasury and imposing bylaws on the subscribers. It was, moreover, in this period that the system of Lloyd's agencies was initiated and the duties defined.

Incorporation, 1871.—In 1871 the control over the affairs of the society by its committee was consolidated by the act of incorporation (Lloyd's act, 1871), which formed the constitution of Lloyd's as it has continued to exist. The society was given power to make its own bylaws, to acquire real and personal property and to do all acts in its corporate name. By the act of 1871 the society was restricted to marine insurance but by an act of 1911 it was empowered to carry on insurance of every description.

Although individual initiative is still a most striking characteristic of Lloyd's, the powers and activities of the corporate body have increased. The measures designed to make the security of a Lloyd's policy unquestionable were taken almost entirely after the act of 1871. Under the Assurance Companies acts, 1909 and 1946, consolidated by the Insurance Companies act, 1958, special provisions are set forth to regulate Lloyd's underwriters. See also **LLOYD'S REGISTER OF SHIPPING**.

Straus, *Lloyd's: a Historical Sketch* (1937); C. E. Golding and D. King-Pagge, *Lloyd's* (1952); D. E. W. Gibb, *Lloyd's of London* (1957). (C. W.; X.)

LLOYD'S REGISTER OF SHIPPING, a society whose main purpose is the survey and classification of merchant shipping and whose standards for the construction and maintenance of ships have been accepted throughout the world. The society is governed solely by the industry it serves and its revenue is devoted to the maintenance and improvement of its services. International in scope, its head office is in London. Like the insurance institution known as the Corporation of Lloyd's (see *LLOYD'S*), it originated in the 17th-century coffeehouse kept in London by Edward Lloyd. Among the men who conducted their business there the need was felt for some guide as to the ships available. To meet this need a group of underwriters combined in 1760 to issue a register, the first known edition of which appeared in 1764. In the first register, ships were graded according to their condition and assigned classes, indicated by letters. The symbol of "A1" for the highest class of ship was introduced in 1775 and has since passed into many languages, either as "A1" or "A1 at Lloyd's," as a connotation of excellence. Nowadays there is only one class, which for ocean-going iron and steel ships is symbolized by "100A1."

In 1834, after some rivalry with the shipowners, issue of the register was placed under the control of a society to be known as Lloyd's Register of British and Foreign Shipping ("British and Foreign" later deleted), and for the first time standard rules for shipbuilding were issued. Management of the society in its new form was vested in a committee composed of merchants, underwriters and shipowners of London; the committee came to include shipbuilders, engineers, steelmakers and representatives from other parts of the U.K. and from 13 other maritime countries. In addition to an international technical committee, which deals with the formulation of rules, there are local committees at Liverpool and in Scotland, and national committees in Australia, Canada, Denmark, Finland, France, Greece, India, Italy, the Netherlands, New Zealand, Spain, Sweden and the United States. The first

volume of the register's book contains particulars of all known sea-going merchant ships of 100 or more tons gross, while the second, third and fourth volumes contain additional technical information and lists of shipowners, shipbuilders, dry and wet docks throughout the world, harbours, etc. Registers of British and American yachts, and quarterly and annual statistics regarding ships under construction and ship casualties, are also published. The society's main activity is the supervision of the construction of ships and their machinery, from the examination of plans and testing of materials, through the various stages of building to the trial trip, and the holding of regular periodical surveys throughout the ship's life to ensure that it is fit to retain the society's class. The society publishes comprehensive rules providing standards of construction for ships and for their propelling, electrical and refrigerating machinery. A staff of over 1,100 surveyors, stationed at all principal ports and at engineering centres throughout the world, is employed to carry out the highly specialized duties, which include the calculation and fixing of load lines on behalf of 49 different nations in accordance with the International Load Line convention, 1930, and the issue of safety certificates under the International Convention on the Safety of Life at Sea, 1948. A comparatively new aspect of the society's work is the inspection of material for land installations such as oil refineries, hydroelectric and atomic power stations, railways and chemical plants. This work, increasing steadily, is performed by a special nonmarine department.

(E. E. PA.)

LLULL, RAMON (Castilian, RAIMUNDO LULIO; English, RAYMOND LULL or LULLY) (c. 1234–1316), Catalan author, lay missionary, philosopher in the Augustinian tradition, the first great mystic of the Iberian peninsula. He wrote some 292 works in Catalan, Arabic and Latin, most of which survive, although no Arabic manuscripts are known. The creator of literary Catalan, which he used not only in poetry, novels and mystical works, but also to discuss theological, philosophical, moral and scientific subjects before any other romance vernacular had been used professionally in this way, he is best known in the history of ideas as the inventor of an "art of finding truth" (*ars inveniendi veritatis*) primarily intended to support the Catholic faith in missionary work but also designed to unify all branches of knowledge.

Born in Majorca (Mallorca), shortly after its reconquest from the Moors, Lull grew up in a kingdom with large non-Christian minorities, and the national preoccupation with their conversion had a decisive effect on his life and writings. On his entering upon a religious way of life (c. 1263), after seeing five visions of Christ on the cross, he made a threefold resolution: to seek martyrdom; to found schools of oriental languages for missionaries; and to write "the best book in the world against the errors of the infidel." He then spent some nine years in preparation for his mission, during which he composed his longest book (*Llibre de contemplació*, a meditative work with an elaborate symbolic structure containing numerous separate opuscula, written first in Arabic and then in Catalan), and the *Llibre del gentil e los tres savis*—an account of a fictitious theological discussion between a Jew, a Christian and a Muslim which influenced the *Libro de los estados* of Don Juan Manuel (q.v.). Neither of these, however, was the "best book in the world" contemplated in his third resolution, which first took shape as the first version of his "Art," written c. 1272, after a mystical "illumination" on Mt. Randa in which he saw how everything in the universe could be related to the Godhead through the divine attributes (goodness, greatness, etc.), which he called "Dignities." The rest of his life was spent in constant traveling, writing, preaching and lecturing on the "Art"; in missions (Tunis 1292, Bougie 1307, Tunis 1315) and disputations; and in pleading with kings and successive popes for support, especially in connection with the colleges envisaged in his second resolution. Only King James II of Majorca could be persuaded to establish one (at Miramar, 1276, apparently abandoned soon after 1292), but the Council of Vienne (1311–12) endorsed Lull's proposals, and a number of schools of oriental languages were founded in the years after his death. According to pious tradition, this came in the form of the martyrdom he had so long desired, by stoning in Bougie (? Jan. 1316). His last three works were un-

doubtedly written in Tunis in Dec. 1315. He had never taken holy orders (though long attracted by both the Dominicans and Franciscans), but there is a late tradition that he joined the Third Order of St. Francis in 1295. He is revered by Franciscans as "*Doctor Illuminatus*," and his feast day is kept throughout the Order on July 3. Traditionally regarded as a saint in Majorca and elsewhere, he has never been officially canonized, though in 1858 his *cultus* was confirmed by Pius IX.

In his mystical writings he belongs to the Franciscan tradition, though his best-known mystical work, *Llibre d'amic e amat* (*Book of the Lover and the Beloved*; included in book v of *Blanquerna*), is strongly influenced by Muslim Sufi mysticism (see *SUFISM*), and his longer mystical treatises—*Art amativa*, 1290; *Arbre de filosofia d'amor* (*Tree of Love*), 1298—are so dependent on the methods of his "Art" as to stand outside the main stream of that tradition. His didactic allegorical novels, the *Llibre d'Evast e Blanquerna* (?1284) and the *Llibre de meravelles*, or *Felix* (c. 1288), occupy a prominent place in the rise of prose fiction, the former being a well-developed utopian romance, the latter including the famous *Llibre de les besties* (*Book of the Beasts*), a collection of animal apologues in imitation of the Arabic *Kalila wa Dimna* (see *ARABIC LITERATURE: Belles-lettres*). His *Llibre qui és de l'orde de cavalleria* (between 1275 and 1281), a manual of chivalry, was widely translated, an English version (made from the French) being among the books published by William Caxton (q.v.); and his *Arbre de sciència* (1295) was one of the last great medieval compendia of universal knowledge. His lyrical poetry combines great simplicity with sublimity of thought.

Most of Lull's nonliterary writings are connected with his "Art," which was (like the *Summa contra gentiles* of St. Thomas Aquinas completed in 1264, only a few years before Lull's "Illumination") an attempt to place Christian apologetics on the level of rational discussion, mainly to meet the needs of disputation with the Muslims—against whom "arguments from authority" based on Scripture (the basic approach in Dominican disputations with Jewish theologians during the previous generation) were inapplicable. Its use of complex semimechanical techniques involving symbolic notation and combinatory diagrams justifies its classification among the antecedents of both "logic machines" and modern symbolic logic, but these techniques are purely ancillary, and should not be allowed to obscure its fundamental nature. Basically the "Art" works by relating all forms of knowledge (including religious belief) to the manifestation of God's "Dignities" in the universe, taking for its point of departure the monotheistic vision common to Judaism, Islam and Christianity, and their acceptance of a broadly Neoplatonic exemplarist world-picture, and arguing its way analogically up and down the "ladder of being." Lull uses it in apologetics to draw specifically Christian conclusions concerning the Trinity and the Incarnation from generally accepted views regarding the active nature of the divine attributes. It seems probable that his combinatory techniques were modeled on those developed in the medical field to deal with combinations of the "four elements" in connection with humoral pathology, and that Lull hoped that the analogy of the elements would provide, as it were, a "scientific" basis for argumentation at higher levels of the "ladder"—since all levels were analogically related to each other, being reflections of the same divine exemplar, their Creator. The more "elemental" features of the "Art" were, however, dropped when the "Dignities" were reduced (c. 1289) from 16 to 9, and it is in its ternary—or more obviously Trinitarian—form that the "Art" was known to later thinkers, most of whom used its final version: the *Ars Magna* [*Generalis Ultima*] of 1305–08. Its apologetic application also receded into the background after Lull's death, and it was as a universal system of knowledge that the "Art" remained influential until long after the Renaissance, ultimately inspiring Leibniz' dream of a "universal algebra." See *LOGIC, HISTORY OF: Modern Logic: Leibniz*.

LLWCHWR, an urban district in the Gower parliamentary division of Glamorgan, Wales, is situated 5 mi. N.W. of Swansea and bounded on the west by the Loughor river. Pop. (1961) 25,013.

The district comprises four small towns: Gorseinon, the administrative and business centre, with steel and tinplate works; Loughor, the old borough which gives its name to the district and contains the ruins of a 13th- to 14th-century castle, a Perpendicular church and a fine modern bridge; Gowerton, a modern steel town where a "Flannel and Pleasure" fair has been held annually from early times; and Pontardulais, a modern tinplate manufacturing and coal-mining town, possessing the 12th-century church of St. Teilo, isolated on the river plain a little way out of the town. Pontardulais has gained a reputation for its music.

LOACH, any of the small but elongate carplike fishes of the fresh-water family Cobitidae. More than 200 species are known, mostly from mountain streams in central and southern Asia; 3 species occur in Europe and 1 in Ethiopia. Few species attain a length of 12 in. The typical loach has very small scales; three to six pairs of barbels; the air bladder reduced and wholly or partly enclosed in a bony capsule; and the pharyngeal teeth in a single series. In low and stagnant ponds, loaches come to the surface and swallow air, the intestine serving as an organ of respiration.

The stone loach (*Nemachilus barbatula*) and the spined loach (*Cobitis taenia*) range through Europe and northern Asia to Japan. One species of European loach, *Misgurnus fossilis*, is called weatherfish because of its heightened activity during periods of rapid change in barometric pressure, as occurs prior to a storm.

LOANGO, a region of the west coast of Africa, extending north from the mouth of the Congo. In the 17th and 18th centuries it formed a kingdom of that name (also known as *Brama*) but after 1885 the country was divided between French Equatorial Africa, the Portuguese district of Cabinda and the Belgian Congo. The inhabitants belong to the Bantu group of Vili (subgroup of the Kongo [q.v.]), formerly known as the Fiote. Loango town is now an insignificant coastal place having been superseded by the port of Pointe-Noire.

The early history of Loango is unknown. During the 15th and 16th centuries Portuguese merchants visited the kingdom which appears to have belonged to the kingdom of Congo, located south of the Congo river. It achieved independence toward the end of the 16th century. The kingdom was bounded to the north by Mayombe, east by the Mayombe plateau, and south by the Kikongo kingdom. It was divided into four provinces. During the 17th and 18th centuries the country was an important source of slaves for the new world. Loango was visited by Portuguese and Dutch ships and later principally by French and English. Roman Catholic attempts at missionary work were unsuccessful. By the middle of the 19th century the kingdom had been reduced in influence.

In 1883 the king of Loango signed a treaty placing his country under the protection of France; it became part of the Middle Congo (Moyen-Congo) territory and, since 1958, of the Republic of Congo (Brazzaville).

(H. A. Wf.; Hu. Ds.)

LOBACHEVSKI, NIKOLAI IVANOVICH (1792–1856), Russian mathematician, the founder of a system of non-Euclidean geometry, was born in Nizhni-Novgorod (now Gorki) on Dec. 2 (new style; Nov. 21, old style), 1792. He studied in Kazan university, began teaching there in 1812, and was professor from 1822 to 1846. Lobachevski was one of the first mathemati-

ticians to become convinced of the possibility of a geometry different from that of Euclid and the first to publish, in 1829, such a system (*see* GEOMETRY, NON-EUCLIDEAN). Presented in a form hard to understand, it was met in the beginning with derision. Some recognition came during his lifetime (election to the Göttingen Scientific society in 1842) but full appreciation of his work came only at the end of the century, when the non-Euclidean geometries, by suggesting a new way of looking at space, had important implications for theoretical physics and the development of the theory of relativity. In addition to his work in geometry, Lobachevski proved an excellent administrator. At Kazan university, where he was rector from 1827 to 1846, he helped organize the teaching staff and arranged and enriched its library. He also furnished instruments for its observatory, collected specimens for its museums and provided it with proper buildings. In order to be able to supervise the erection of the buildings, he studied architecture. Efficient measures taken by Lobachevski during an outbreak of cholera in 1830 and a disastrous conflagration in 1842 prevented great losses in personnel and equipment of the university. He died at Kazan on Feb. 24 (N.S.; 12, O.S.), 1856.

Geometrische Untersuchungen, first published in 1840, was translated into English by G. B. Halsted (1891; new ed., 1914).

See F. Engel, *N. I. Lobatchewsky* (1899); A. Vucinich, "Nicolai Ivanovich Lobachevskii: the Man Behind the First Non-Euclidean Geometry," *Isis*, vol. 53 (1962). (G. V. R.)

LOBANOV-ROSTOVSKI, ALEKSEI BORISOVICH, PRINCE (1824–1896), Russian diplomat and statesman, minister of foreign affairs from March 1895 to his death, was born on Dec. 30 (new style; 18, old style), 1824. He began his career in the diplomatic service in 1844 and later held posts in Berlin, Paris and Istanbul, where he became minister in 1859. He retired in 1863 but resumed his career in 1878, when he became ambassador at Istanbul before being transferred to London in 1879. He was sent to Vienna in 1882 and to Berlin in 1895. During this time he was one of the most influential of Russian foreign representatives. On March 10 (N.S.; Feb. 26, O.S.), 1895, he succeeded N. K. Giers as foreign minister.

In European affairs Lobanov was a firm supporter of the Franco-Russian alliance, but he sought amicable relations with Austria-Hungary and Germany. He was also able to settle the long-standing quarrel with Bulgaria in 1896. In regard to the crucial question of the Turkish straits, Lobanov believed that under the existing circumstances the Ottoman empire was best suited to play the role of guardian; and, not wishing to compromise Russo-Turkish relations, he refused to co-operate with Great Britain over the issue of the Armenian massacres. Lobanov's chief efforts, however, were directed toward the far east, where Japan had imposed the treaty of Shimonoseki on China. In co-operation with France and Germany, Russia induced Japan to surrender its acquisitions on the Chinese mainland (1895); and on June 3, 1896, Russia signed a defensive alliance with China directed against Japan. In return, China agreed to allow Russia to extend the Trans-Siberian railway across Manchuria to Vladivostok. On Aug. 30 (N.S.; 18, O.S.), 1896, traveling from Kiev to meet the German emperor William II in Silesia, Lobanov died suddenly at Shepetovka, on the Russo-Austrian frontier. (B. J.)

LOBBYING. In its original meaning, "lobbying" referred to the efforts of individuals to influence the votes of legislators, generally in the lobby outside the legislative chamber. In its broadest modern sense it means any attempt by individuals or groups to influence the decisions of government. It is most commonly associated with the activities of private interest groups, often called pressure groups, although even public officials may be said to lobby when they attempt to influence the making of public policy by other officials.

Lobbying in some form is inevitable in any political system, for politics is a struggle for power. Any group that makes claims upon other groups or upon society finds it well-nigh impossible to stay out of politics, for even in a simple society the power of government to say who gets what is too important to ignore. Even in a strictly laissez-faire system—assuming such a system to be possible—the government still would have to provide the

legal framework within which social action would take place. In a modern industrial society, where regulation extends in some degree to almost all human activities and relationships, the decisions of public officials may be of crucial importance; they are and must be subject to the close and continuous attention of the groups they affect. Conversely, the government must heed the pressures of group demands. Even the most authoritarian rulers must take into account the army, the priesthood or some other politically influential elements. In a free society, the government's obligation to consult the governed is recognized and institutionalized through guarantees of freedom of speech, press and assembly, and the right of people to petition the government for a redress of grievances. Lobbying occupies a preferred position in the constitutional system because it is necessary to the preservation of self-government.

United States.—If lobbying is necessary for self-government, why does it have such a bad reputation in the United States? In the 19th century its poor reputation was deserved and much of it has hung on. Lobbying was then largely a matter of personal influence in which many lobbyists plied legislators with wine, women and money. Moreover, the moral climate of public life was low. U.S. senators were not chosen by the people but by state legislators and many of them virtually belonged to the interests that engineered their selection. This situation has changed. Lobbying never will be wholly above suspicion, but several congressional investigations in the 20th century have made it clear that modern pressure activities are rarely corrupt; they have become increasingly indirect and are largely group efforts rather than individual efforts.

Several reasons for these trends may be suggested. Exposure of corruption by muckraking writers at the turn of the century undoubtedly had some effect. Direct election of senators and the opening of legislative hearings to the public diminished the influence of interest groups enjoying favoured access to officials. But most important, perhaps, has been the growth of giant associations. The typical national association is a federation of state and local units, capable of operating at every level of government. Representative examples of this kind of association are the National Association of Manufacturers, the Chamber of Commerce of the United States, the American Medical association, the American Federation of Labor-Congress of Industrial Organizations, the American Farm Bureau federation and the National Farmers union. With their large memberships and resources the associations have found it more effective to lobby through their members and to create a sympathetic public opinion than to court individual officials. Besides, the associations have too large a stake in their reputations to risk scandal.

One of the reasons for the frequent criticism of lobbying in the United States is to be found in the fact that lobbies can easily be seen. The group struggle is brought out into the open by the structure of government and the character of political representation. Because they were more concerned with protecting minority rights than with effectuating majority will the makers of the federal constitution deliberately set obstructions in the way of control by a temporary majority. They provided a separation of powers that institutionalized conflict between president and congress and not even the unifying influence of party has been able to overcome it. They gave to each branch of the government some power to check the action of the other branches, thus making obstruction easy and co-operation difficult. There are, moreover, not 1 but 51 governments in the United States, each exercising powers guaranteed to it by a hard-to-amend constitution. In this framework the national parties are merely federations of state and local parties, incapable of carrying out a promised program of action. Power is further dispersed in congress among standing committees, and localism is strengthened by the individual member's dependence on his constituency. With political power so fragmented the group struggle is bound to be public. This makes it easy for participants to denounce the lobbying of the other side; as Sen. Jim Reed once said, "a lobbyist is anyone who opposes legislation I want."

Lobbying in the United States takes many forms. Group in-

terests may be represented openly before legislative committees and administrative tribunals. Public officials may be "button-holed" in legislative lobbies, offices, hotels, bars, restaurants or private homes. Letters may be written or telephone calls made to public officials, and "grass-roots" campaigns may be organized for this purpose. Organizations seeking to influence public policy may provide favoured candidates with money and services—including radio-television coverage for public speeches and friendly mention or outright endorsement in the publications of the organization. Research and writing services may be made available to public officials. Massive public relations campaigns employing all the techniques of modern communication may be launched to influence public opinion. The persons who lobby in these ways may be full-time officials of a powerful association, individual lobbyists with many clients who pay for their services, or ordinary citizens who take the time to state their hopes or grievances. Some of the most effective lobbyists are former congressmen or administrative officials whose principal asset is that they "know their way around."

The regulation of lobbying poses difficult problems. It is necessary somehow to curb the excesses of pressure groups without restricting their right to represent their members. The national government and more than half the states regulate lobbying. Most laws relating to lobbying, such as the Federal Regulation of Lobbying act (1946), which requires that lobbyists register and report contributions and expenditures and that groups they represent must make similar reports, are based on the assumption that lobbyists cannot do much harm if their activities are publicized. The efficacy of these laws is doubtful; the 1946 federal law, for instance, is poorly written, has no provision for proper administration or enforcement or even for effective publicity, and requires only summary and superficial information. Moreover, indirect lobbying—group activity designed to influence government by shaping public opinion—has proved almost impossible to regulate. Campaigns addressed to the public through newspapers, magazines, television, radio, books, pamphlets and public speeches are protected by constitutional safeguards. The supreme court of the United States has made clear its intention not to permit laws for the regulation of lobbies to infringe upon freedom of speech or of the press. Although the Federal Regulation of Lobbying act covers efforts made "directly or indirectly" to influence the passage or defeat of any legislation by congress, the supreme court in 1953 (*United States v. Rumely*, 345 U.S. 41) said that "lobbying" should be construed in its commonly accepted sense as "representations made directly to the Congress, its members or its committees." The next year, in upholding the constitutionality of the lobbying law (*United States v. Harriss*, 347 U.S. 612), the court re-enforced its interpretation of the narrow scope of the law.

Great Britain.—Lobbying flourishes in Great Britain as it does in the United States, but not in the same political environment. Different procedures are required in Great Britain to deal with disciplined political parties and a governmental structure that concentrates power in a cabinet that is able to control both legislature and administration. British interest groups show a coherence and concentration of power similar to that of the parties and government. For example, about 90% of British farmers are members of the National Farmers union, while only about 30% of U.S. farmers are thus organized; about half of all British workers belong to labour (trade) unions, compared with 25% of U.S. workers; and the Federation of British Industries represents directly or indirectly about 85% of all manufacturing concerns employing ten or more workers, far more than any U.S. business association. The leaders of these giant organizations exercise such authority that they may bargain directly with party leaders who control the government; indeed, their co-operation is indispensable to the success of the detailed and technical regulations imposed by government on most aspects of British economic life. In addition to such organizations representing economic interests, many groups promote causes reflecting the diversity of British society. They rarely sponsor American-style public relations campaigns, however; their appeals are made directly to party and administration leaders rather than to the electorate and to individual legis-

lators. The vigour and effectiveness of lobbying in Great Britain, where it was formerly assumed there was little, suggest that comparative analyses will document similar activity in all relatively well-developed systems.

Ehrmann (ed.), *Interest Groups on Four Continents* (1958); S. H. Beer, "The Future of British Politics," *Political Quarterly*, 26: 33-43 (1955); "Pressure Groups and Parties in Britain," *American Political Science Review*, 50:1-23 (1956). (R. K. H.)

LOBE, any round projecting part, specifically the lower part of the external ear, one of the parts into which the liver or lung is divided, also one of several parts of the brain, divided by marked fissures. (See **RESPIRATORY SYSTEM**, **ANATOMY OF**; **BRAIN: Anatomy of the Brain**.) The diminutive "lobule" is applied to a similarly shaped portion of a gland, e.g., breast, liver, when of microscopic size.

LOBELIA, the common and scientific name of the typical genus of the family *Lobeliaceae*, refers to about 250 species of plants, natives of nearly all the temperate and warmer regions of the world, excepting central and eastern Europe and western Asia. They are annual or perennial herbs or undershrubs, rarely shrubby, although the "tree" lobelias found at high elevations on the mountains of tropical Africa are remarkable arborescent forms. *L. dortmanna* (water lobelia) occurs throughout the north temperate zone. *L. urens* (acid lobelia) is found locally in damp pastures in England and western Europe. The genus is distinguished from *Campanula* by the irregular corolla and completely united anthers, and by the excessive acidity of the milky juice.

The species earliest described and figured appears to be the North American *L. cardinalis*, under the name *Trachelium americanum sive cardinalis planta*, "the rich crimson cardinal's flower"; Parkinson (1629) says, "it groweth neere the riuer of Canada, where the French plantation in America is seated." It is a native of the eastern United States (see **CARDINAL FLOWER**). This and several other species are cultivated as ornamental garden plants, e.g., dwarf blue *L. erinus* from south Africa, which, with its numerous varieties, forms a familiar bedding plant, much used for edging. *L. splendens* and *L. fulgens*, growing from one to two feet high, from Texas and Mexico, have scarlet flowers; *L. tupa*, a Chilean perennial six to eight feet high, has reddish or scarlet flowers; *L. tenuior*, with blue flowers, is Australian and grown in the greenhouse, while *L. georgiana*, from North America, as well as *L. siphilitica* and its hybrids, also have blue flowers. The hybrids

raised by crossing *cardinalis*, *fulgens*, *splendens* and *siphilitica* constitute a fine group of fairly hardy and showy garden plants.

The species *Lobelia inflata*, the Indian or wild tobacco of North America, has been used in medicine, the entire herb, dried and in flower, being employed as an expectorant. The species derives its specific name from its characteristic inflated capsules. It is somewhat irritating to the nostrils, and is possessed of a burning, acrid taste. The chief constituent is a volatile liquid alkaloid named lobeline, which occurs to the extent of about 0.3%; it is similar in physiological action to nicotine. Lobeline is pungent, with a tobacco-like odour, and is very poisonous. From it is made

JOHN H. GERARD

FLOWER SPIKE OF BLUE LOBELIA
(LOBELIA SIPHILITICA)

a medicinal tincture of lobelia, used in treating spasmodic asthma and chronic bronchitis. Fatal cases of poisoning are not uncommon, even if only a few leaves or capsules and their seeds are ingested. Milder manifestations include vomiting, nausea, coma or convulsions. The drug has also been incorporated in compounds used to discourage the smoking of tobacco products.

(N. Tr.; X.)

LOBITO, a town on the west coast of Africa, is situated in the Benguela district of the Portuguese overseas province of Angola, 240 mi. S. of Luanda. The mean annual temperature is 18°–24° C. (65°–75° F.) and the average rainfall, 1½–1¾ in. The hottest and wettest months are February and March. In 1955 the population was estimated to be 31,630, made up of 6,390 whites, 420 mestizos and 24,820 Africans. By 1960 it was probably about 9,000 Europeans, 700 mestizos and 31,000 Africans. There are seven primary schools and four secondary schools. Roman Catholicism is the predominant religion.

Lobito is served by a municipal bus service and has an all-season airport. It is the starting point by road for the Huíla and Huambo uplands and for the whole of Angola up to the frontier with the Republic of the Congo; and it is linked by rail with the other principal cities of Angola and with the Republic of the Congo (Katanga), Rhodesia and the east coast of Africa. There are regular sailings of passenger-carrying cargo ships to all parts of the world. The bay of Lobito is one of the finest natural harbours on the whole west African coast, being protected by a natural mole of sand about 3 mi. long and 220 yd. wide. The quays, accommodating vessels with a draft of 34 ft., extend for 1,230 yd. There are about 5½ ac. of covered storage space.

The main industries are metalworking, shipbuilding, the manufacture of cement, building materials, food and clothing. The principal agricultural products are sisal, peanuts, castor oil, coconuts, maize, beans and potatoes. Citrus fruit, pineapples and mangoes are grown. The main exports are minerals and various agricultural products, such as maize, beans and sisal.

Lobito was founded in 1843 as the result of a royal order of Maria II, made in response to the repeated requests of the inhabitants of Benguela for a healthier and geographically and strategically more favoured place to live. Very little in the way of development occurred, however, before the building of railways in the early 20th century.

LOBO, FRANCISCO RODRIGUES (1579–1622), Portuguese poet, best known for his pastoral eclogues, was born in 1579 at Leiria, where he lived until he went to the University of Coimbra to study law. After taking his degree he entered the service of the duke of Braganza. Lobo was drowned in the Tagus, probably before the end of 1622. Some biographers have traced his Jewish descent and possible noble birth, but this is uncertain.

His first book of poems—*Romances* (1596)—reveals a refined sensibility and skill in describing the moods of nature. At this time he was deeply influenced by Luis de Góngora y Argote, and 57 of the 61 poems were in Spanish, which remained a second language for Portuguese writers until the end of the 17th century.

Lobo's last work, *Jornada* (published posthumously, 1623), a series of short poems welcoming Philip III to Lisbon, was written in pure Castilian. Although Lobo preferred writing pastoral poems—e.g., *Églogas* (1605)—he also wrote an epic in 20 cantos on Dom Nuno Álvares Pereira, *O Condestabre de Portugal* (1609), but the narrative is monotonous and lacks Camões' vigour and inspiration. Lobo's pastoral trilogy—*A Primavera* (1601), *O Pastor Peregrino* (1608) and *O Desencantado* (1614)—contains his best eclogues. In the countryside where he was brought up, on the banks of the rivers Lis and Lena, his shepherds and shepherdesses discourse wittily on the wiles and whims of love and the weariness of life. A similar pessimism, tempered with philosophical resignation, informs the prose dialogue *Corte na Aldeia* (1619), in which the author discusses, through his characters, such subjects as the harm resulting from the extinction of the Portuguese court under Spanish rule, the best system of education and the new theories of literary expression. Lobo has won a high place in Portuguese literature for his vivid descriptions of the countryside and for the sincerity of his lyrics.

See R. Jorge, *Francisco Rodrigues Lobo* (1920); C. A. Ferreira, "Francisco Rodrigues Lobo—Fontes inéditas para o estudo da sua vida e obra," in *Biblos*, vol. xix (1943). (L. DE S. R.)

LOBSTER, an edible crustacean found on the coasts of the north Atlantic and the Mediterranean. The name is sometimes applied to any of the larger Crustacea (*q.v.*) of the shrimplike Decapoda used for food.

True Lobsters.—The true lobsters (family Nephropsidae) are distinguished by having the first three pairs of legs terminating in chelae or pincers, the anteriormost pair being the largest. The dark greenish common lobster (*Homarus gammarus*) is found on the European coasts from Norway to the Mediterranean. The closely related American or northern lobster (*H. americanus*), generally treated as a separate species, ranges from Labrador to North Carolina. Although uncommon, giant American lobsters measuring about 2 ft. long and weighing more than 30 lb. have been taken; a weight of 44½ lb. has been recorded. The average-sized lobster in a catch is about 9 in. in total length (from tip of rostrum to end of tail) or 3½ in. in carapace length (from eye socket to end of dorsal shield along the centre line). Although conservation laws vary considerably, most regulations require that a lobster of carapace length less than 3½ in. (determined quickly by the use of a simple measuring device) be returned to the sea. The European lobster rarely reaches 10 lb. in weight, though individuals of 15 lb. have been found. A third species (*H. capensis*), 4–5 in. long, from the Cape of Good Hope, is of no economic importance.

The principal foods of the omnivorous and scavenging adult are fish, alive or dead, and bottom-dwelling invertebrates, especially small mollusks and such larger ones as can be crushed. Vegetable matter is eaten occasionally. Cannibalism is not unknown.

The true lobsters are the basis of important fisheries. They are generally fished in relatively shallow water, 5 to 50 fathoms, from more or less rocky bottoms by means of lobster pots or creels,

FROM F. H. HERRICK, "THE NATURAL HISTORY OF THE AMERICAN LOBSTER," BUREAU OF FISHERIES BULLETIN, VOL. 29
FIG. 1.—LARVAL STAGES OF THE AMERICAN OR NORTHERN LOBSTER (*HOMARUS AMERICANUS*): (A) SECOND, "SWIMMING OR" "MYSTIC" STAGE, 9 MM.; (B) SIXTH STAGE, 16 MM.

rectangular traps of wooden slats, or frames covered with netting and provided with a funnel or two permitting entrance but preventing escape. Oily fish, fresh, salted or partially decomposed, are the greatest attraction as bait. Lobsters constitute a multi-million-dollar industry in the United States, where more than 30,000,000 lb. are caught annually; they are marketed fresh, frozen or canned.

The Norway, or Dublin, lobster, the Italian scampo (*Nephrops norvegicus*), also called maiden lobster because of its slender shape as compared with that of the common lobster, averages about 6 in. in length; 8½- to 10-in. specimens are rare. Found in the Faeroes and off Iceland, it ranges from the coasts of Norway, Scotland and Ireland to the Mediterranean.

Spiny Lobsters.—The names spiny lobster, rock lobster, sea-crawfish, langouste, langosta and kreef refer to members of the family Palinuridae, readily distinguished from the Nephropsidae by the lack of prominent pincers and the presence of a more or less spiny carapace or shield. Their distribution is world-wide in tropic and subtropic latitudes and in certain temperate regions. Several species are of major economic importance. Preferring coral reefs or rocky areas, palinurids may also be found over smoother sandy bottoms, if sheltered niches or even brush piles are available; muddy grounds are avoided. Like the true lobsters, all are omnivorous and scavenging and consume considerable invertebrate food; fish heads are the favoured bait.

The European *Palinurus elephas* (formerly, *P. vulgaris*) ranges from Great Britain and France to the Mediterranean. Along the Atlantic and Gulf coasts of the Americas, from Bermuda, the Bahamas and Florida southward through the Caribbean to Rio de Janeiro, *Palinurus argus* is the important species. On the west coast from Monterey to the Gulf of Tehuantepec *P. interruptus* is fished.

Most widely distributed is *Jasus lalandei*, believed to be a complex of several closely related species that range along the coasts of western and southern Africa, Australia, New Zealand, Tasmania and about the islands of Juan Fernandez (off Chile), Tristan da Cunha (south Atlantic) and St. Paul (south Indian Ocean); some specimens attain a length of 20 in. and a reputed weight of 10½ lb. Various other spiny lobsters are fished throughout the Indo-Pacific area, including Japanese waters. The Florida and western American spiny lobsters, taken principally by trapping, average only a few pounds in weight because of heavy fishing; however, 6½ pounders, 18 in. long, are caught occasionally, and a few weighing more than 15 lb. have been reported from Mexican and Central American waters.

Traps similar to the New England lobster pots, and occasionally spears and a modification of the dip net ("bully-net"), are used in American fishery, but South African fishery, because of the abundance of *Jasus lalandei*, employs almost exclusively the simple hoop net between the low-water mark and the 25-fathom line.

The bulk of the catch, frozen or canned, is exported as lobster tails, chiefly to the United States.

Other "Lobsters."—The Murray lobster, of Victoria, New South Wales and South Australia, is a large species of fresh-water crayfish (*Euastacus armatus*) of the family Parastacidae, about 7-10 in. long, much used for food in Australia.

Some of the larger-clawed true shrimp (family Palaemonidae) are also loosely called lobsters. They are fished in baskets, nets or traps in tropic and subtropic fresh and occasionally brackish waters in many parts of the world.

Natural History.—A true lobster is hatched from the egg in a shrimplike, free-swimming form (naupliosoma). With the eighth molt, it becomes quite definitely a bottom-dwelling, juvenile lobster. In the spiny lobsters the naupliosoma hatched from the egg soon molts into a phyllosoma. This unique larva is quite transparent except for the pigmented eyes. Several phyllosome stages later, the puerulus, almost a young spiny lobster, develops.

Larval molts appear to succeed one another with considerable rapidity and without much difficulty; growth in the adult is a much more serious proceeding. The stout exoskeleton prevents increase in body size until there is a literal bursting at the seams. In *Homarus* the "seam" that gives is the chitinous articulating membrane between the hinder margin of the carapace and the fore edge of the tergum of the first abdominal somite. Through that narrow opening passes the entire soft body of the animal, including the relatively huge chelae. The chitinous lining of the foregut (masticatory stomach and esophagus), the hindgut (the intestine) and the endophragmal skeleton are also shed. The latter consists of a series of infoldings of the external skeleton of the thoracic somites for the attachment of muscles.

The body, and the soft cuticle that in the premolt period (endysis) was forming beneath the old shell, in the next few hours expands rapidly in size by the absorption of water. When this periodic increase (about 11%-12%) has reached its maximum, the cuticle begins to harden with a deposition of lime salts. Within an hour the new shell perceptibly hardens; in six to eight weeks it has the rigidity and strength of the old one. In the soft condition the lobster remains in hiding, for it is at this time easy prey for its enemies. For each successive increase in size, the operation must be repeated. F. H. Herrick (1911) described a large *H. americanus* that weighed 34 lb. and measured about 2 ft. in length. The crushing claw of its pincer was 15 in. long and had a 20½ in. girth; the more slender, half-inch longer toothed, or cutting, claw had a girth of 15½ in. Herrick has estimated that such giants are possibly 50 or more years old.

Food Value.—Lobster flesh is relatively rich in protein; it has almost 62% of the nutritive value of beef. Canadian researchers found that the flesh of the lobster stimulates the stomach glands to a greater secretion of digestive enzymes and acid; it is therefore especially valuable in overcoming functional depression of gastric juice.

LOCAL EDUCATION AUTHORITY: see EDUCATION HISTORY OF.

LOCAL GOVERNMENT. Some degree of local government characterizes every state in the world: the degree is all significant. Local government means authority to determine and execute measures within a restricted area inside and smaller than the whole state. The variant, local self-government, is important for its emphasis upon the freedom of the locality to decide and act.

There is more than a technical importance in the difference be-

FROM C. VON BONDE AND J. M. MARCHAND, "UNION OF SOUTH AFRICA FISHERY BULLETIN" NO. 1
FIG. 2.—STAGES OF THE SOUTH AFRICAN SPINY LOBSTER (*JASUS LALANDEI*):
(A) PHYLLOSOMA, 1.7 MM.; (B) PUERULUS, 22.0 MM.

tween the two terms, because they are related to the distinction sometimes drawn between deconcentration and decentralization. Local government is often, but not necessarily, related to the former; local self-government to the latter. That distinctions have been made is important, even if they are blurred. By deconcentration some have meant that for the mere convenience of a congested central government some functions have been devolved to administration on the spot, rather than from the centre, but still administered through officials appointed by and responsible to the centre. Authority and discretion are vested in the centre. On the other hand, decentralization represents local government in areas where the authority to decide has been devolved to a council of locally elected persons acting in their own discretion with officials they themselves freely appoint and discipline.

The term local self-government has been traditionally used of local government in Great Britain and Germany. Thus the constitution of the Federal Republic of Germany says, "The *Gemeinden* (that is, local authorities) must be safeguarded in their right to regulate, under their own responsibility, all the affairs of local community within the limits of the laws." On the other hand, the constitution of the French fourth republic said, "The French Republic, one and indivisible, recognizes the existence of local administrative units. . . . The local administrative units shall be governed freely by councils elected by universal suffrage." This expresses the spirit of deconcentration. The Union of Soviet Socialist Republics constitution (chap. VII) makes provision for "the local organs of state power," but offers no breath of decentralization.

However tightly bound to the central office's authority and regulations, a degree of discretion in its local officials is unavoidable. Often, again, the fairly pure organs of local self-government, e.g., a British county borough council, are obliged to execute the purposes of the central government. Primarily units of local self-government, they are simultaneously units of local obligation acting as ordered by the central government, for services, e.g., education and police, willed and imposed by it.

Thus modern local government has a twofold aspect—it is a mixture of both deconcentration and decentralization, of central convenience and an acknowledgment that not all authority ought to be exerted by the centre. The mixture is revealed by the extent to which some of the powers exercised by local government units are exercised compulsorily and under fairly strict control by central authority with financial assistance, while others are not. This mixture produces the high complexity of modern local government. Further, local government is a departmentalization of the state's work, based on the territorial distribution of services, as contrasted with (1) division into departments at the centre, or, (2) as in the decentralization of functions to public corporations, such as the British Coal board or the metallurgical trust (*Glavki*) in the U.S.S.R. In local government, territorial distribution of power is the essence.

The history of local government in western Europe, Great Britain, the United States and Russia exhibits the growing awareness of its significance. This awareness is a product of a development of parochial and town life which began long before the modern state emerged between the 15th and 17th centuries. Any central control over these and other areas was, until the 18th century, rather scanty, though sometimes, as under Jean Baptiste Colbert in France or in 17th century Prussia already overlaid by the heavy hand of the central *Intendants* in the former and the war commissariat in the latter. Many Germanic states were nothing but cities; e.g., the Hanse towns. In England and especially New England, the local units, parishes, towns, cities emerged from their origins as spontaneous self-governing units; so also in Russia, although there the tsars took strict control of the cities through their provincial governors and over the *Mir*—the village-cum-agricultural unit—through taxes, the police and the *boyars*; the state colonized some cities from the beginning. The various local units were gradually integrated by the state which exacted obligations from them regarding peace, crime and police duties, taxes, military supplies, assistance to the poor and highways. By ordinances or statutes or judicial decisions local units were subordinated, so that the idea

of an inherent right to self-government was extinguished. By the 19th century all local units were legal creatures of the state, subsidiary in authority on principle and acting independently by suffrage alone.

Indeed, the battle for the continuance of local self-government is desperate though not hopeless. The local freedoms of the 19th century were challenged by (1) speed of communications which has reduced administrative space time; (2) demands of a planned economy; (3) growth of nationwide parties with social welfare programs uniform for all parts of the nation; (4) growth of a consciousness favouring a national minimum of services; (5) realization that the best technical administration of modern utilities requires areas knitted together by a central plan and different from the traditional ones; (6) needs of civil defense against air attack. These are powerful forces working against claims to purely self-regarding government.

More than ever, on the other hand, local freedom is supported by need for (1) intimate local knowledge and variation; (2) intensity of local interest and enlistment of loyalty and co-operation; (3) small areas for easy impact of the citizen-consumers upon officials-producers; (4) an accessible area of political education; (5) counterweight to the abuse of central power; (6) the democratic value of a plurality of political experience and confidence. In all plans, decentralization, whether to a regional corporation such as the Tennessee Valley authority in the U.S., or to reformed traditional units, is pressing, necessary and fruitful.

COMPARATIVE STUDY OF CHARACTERISTICS

The chief characteristics of local government, which may be studied by comparison of Great Britain, France, Germany, the U.S. and the U.S.S.R., are (1) constitutional status; (2) areas and authorities; (3) powers; (4) finance and local freedom; (5) organization; (6) central controls.

Constitutional Status.—In Great Britain, the local authorities are subordinate corporations formed by acts of parliament or charters. Their powers and immunities derive from statute and judicial interpretation. They have many obligatory duties and a vast field of permissive powers. Each authority is independent within the sphere of power authorized by the central government; there is no hierarchy of authorities. Slight tutelary control over the health and roads services of the urban and rural districts has been given to the counties. Local councilors are freely elected and constitute the local executive as well as the legislature. There is no appointment or ratification of local executives by the central government, though certain important local officials require qualifications stipulated thereby. The local authorities combine many functions, and are not, like the school or sanitary districts so frequent in the U.S., single function or authorities created for a specific purpose. The local finances—rates—are locally raised in amount and appropriated in detail with practically no interference by the centre. Though local authorities have considerable freedom to use their permissive powers, and even their obligatory ones, they operate within judicial controls lest they act beyond their powers or are negligent, and are under continuous central administrative controls. A condition of local central partnership characterizes the system. Though the central controls have increased markedly in the last 30 years, local powers have also greatly increased. The local units are powerful. They exercise an important influence over the central administration through their members of parliament, and through their increasingly large representation on advisory councils and committees officially attached to the several departments. The nationwide associations of the different classes of local authorities exercise an advisory and representative influence on the centre and sustain the standard of local administration, as, similarly, the German association, the *Deutscher Städtetag*, does.

French local government differs from the English in being both hierarchical and centralized. Though the municipal code of 1884 gives the municipalities a wide general scope of activity, these communes and *départements* are limited by strong central controls over their budgets, modified for the bigger cities by political influence. The inspectorial system, strong in Great Britain because

the relationship of government to the localities is direct, is of less consequence in the French, where hierarchical control seeps down through the *préfet* of the *département*. Obligatory functions which must be carried out by the municipalities can be inscribed by both the *maire* and the *préfet*. The *préfet* may be removed by the central authority at its discretion—he is appointed by it; the *maire*, until 1884 appointed by the central government, since elected by the local council, is removable by the central government for default in acting as the law requires, and is suspendible by order of the *préfet* for similar cause for from one to three months. Judicial control over the activities of local government is very heavy, culminating in the supreme administrative court, the *conseil d'état*. The rather severe centralization of French local government, a legacy of the *ancien régime*, jolted by the Revolution but radically re-established by Napoleon, is considerably criticized, but decentralization is very unlikely. The rural nature of France, despite many cities, and the fear of the divisive political passions of the people, most recently of the Communist party, militate against local freedom.

German local government (omitting the Nazi interlude) attempted to unite the age-long pride in free and enterprising civic life with the full popular enfranchisement that came first only in 1919. Its hierarchical system, with strong central surveillance reaching back to the 18th century, was a little eased during the Weimar period. The position of the local executives, *Bürgermeister* or *Magistrat*, ratifiable by the central government, was much troubled by the universal suffrage of 1919 which replaced the oligarchic three-class system. A very wide scope of authority was accorded to the *Gemeinde*, whether rural or urban, by the basic laws, such as the Prussian *Stadteordnung* of 1808, the *Kreisordnung* of 1872 and the *Provinzialordnung* of 1873. Though this authority came to be limited by financial stringency, German cities showed great enterprise and developed many utilities. The Nazi system in general kept the framework of areas and authorities but abolished all elections and substituted appointed councilors and executives dominated by Nazi *Gauleiters*. After World War II, the several states were glad to revive local self-government and the constitution guaranteed it.

In the U.S. the main features of the constitutional status of local authorities are the variety of arrangements in the various states and the large degree of freedom of the local units deriving from early English township forms reinforced by migration into new lands. Nevertheless, that freedom is subordinate and defined by state statutes and charters giving corporate status. The special charter, referring to individual cities; the general charter, which is a state-wide municipal code; the charter which confers status by classifying the local units for privileges—these are various means of trying to give the local units a status which relieves them of the need for repeated application to the legislature, while subjecting them to a firm pattern of permissions and limits. Amendments, however, still require suppliancy to the legislature; and growth requires powers in addition to the general grant.

In 26 states home rule charters, granted by the legislature, allow the city to draft its own charter by a local convention, sometimes requiring legislative ratification, sometimes not. Another system allows the local units to choose from among several forms of charter provided in a state general law. There is much independence and vigour, no hierarchy, little central administrative control and much judicial control to hold the units within their charter and statutory position. There are increasing direct relations between federal government and local units.

The local government system of tsarist Russia was one of absolute centralized hierarchy, executed through the governors of the 78 *guberniya*, with police, military and taxation powers, and the scantiest recognition of rights of local government. Provincial and village governments were dominated by the landlords who had an ex officio right to chairmanship of local administration, especially of the *zemstvo*, set up in 1864 to govern the provinces under strict control of the imperial governors. The *zemstvo* (with an indirect and unequal class franchise), nevertheless, made progress in educational, health, welfare and agricultural development in spite of the tsarist techniques of tyranny. The Soviet con-

stitution of 1936 and the decree on the city soviets (1933) and specific economic and social planning decrees give extraordinarily wide specified powers to the local units, but very rigorously subject them to hierarchical control of the next higher authorities upward to the central government of the various republics, and in some cases to the union itself. Authority and direction are heavily centralized and animated in the last resort by the All-Union Ministry of State Administration and the public prosecutors. All units from lowest to highest are manipulated in unity by the ubiquitous activities of the Communist party, the members of which are required by the rules to form cells for administrative "fulfillment."

Generally speaking, then, local government as local self-government is discernible more fully in the British and American environment than elsewhere, rather more in the German than in the French and hardly at all in the U.S.S.R. Yet centralization and control of units originally holding authority themselves are not inconsistent with vigorous first-line activity by the local units in the matters entrusted to them.

Areas and Authorities.—Local authorities in England and Wales are (from smaller units upward): 13,000 parishes (of minimal importance even in rural areas); 1,047 rural and urban districts (mainly health and minor roads authorities and some water supply); 317 noncounty boroughs like the districts, some of which, however, have police forces and elementary education and housing authorities—both about to disappear; 83 county boroughs, being great towns of 50,000 population and above, with the widest scope of local services including the public utilities; and 62 county councils, being mixed urban and rural areas. The county boroughs are independent of the counties; all other units have some of the services in their area rendered by the county council in whose area they fall.

In addition to these authorities, there are 2,000 joint authorities, councils, committees or boards, established to administer burials, water and electricity, sewerage and hospitals. There is a tendency in all countries to rely more upon such unions where the services are of a large-scale nature compared with the traditional units having responsibility. Local authorities are mutually independent: unanimity is required for joint schemes, which are amply permitted in the statutes. Even some counties are far too small for large-scale administration, while extremes of size in area and population may be encountered in each of the above-named classes of authorities.

Areas can be reformed after a procedure of local inquiry conducted by the central ministry of local government followed by the case of the creation and extension of county boroughs by legislation, and in the other cases by central administrative sanction. For the districts a maximum decennial review of areas is called for. In 1926 the creation of county boroughs was set back by the stipulation that the minimum population must be 75,000 in place of 50,000, as the counties suffered from the subtraction of area and taxable capacity. The movement for technically more justifiable regions is strong, but cannot prevail against local inertia and the claim that small areas are needed to activate democratic vitality. Nationalization of the electric and gas utilities facilitated the reform of the local units of production and distribution.

The French local government units are, in a downward order: 90 *départements*; 311 *arrondissements*; 3,031 *cantons*; and 38,000 *communes*. The first and the last are genuine units of local government; the middle two are only convenient administrative subdivisions and electoral, tax and *gendarmérie* districts. The *départements* vary in size from 185 sq.mi. to more than 4,000 sq.mi. with an average population of 500,000. This framework, which serves the centralizing authority of the state, was established in 1790 to unify France by abolishing the traditional 35 *généralités* which partly coincided with and partly cut across the ancient provinces. The *communes* are the basic roots of local government. The name applies to units from the smallest village up to the capital. The span is from several acres to 400 sq.mi.; and from fewer than 100 people to the 3,000,000 people of Paris. Two-thirds have fewer than 500 inhabitants. Powers and practical hierarchical control vary accordingly, within the uniform pattern of the law. Alterations can be made only by parliamentary statute, preceded

by local vote, inquiry and acceptance by the *département* and *conseil d'état*. There is a regionalist movement which has been unsuccessful.

Indeed civil disruption fomented by the Communists in 1947 led to further centralization; France was divided into eight regions centring in the army commands in which all governmental power may instantaneously at need be transferred to the regional super-prefects in emergencies; they are called inspectors general of administration on mission extraordinary, or I.G.A.M.E.

The German areas of local government are (in Germany as a whole): more than 50,000 *Gemeinden* (like the communes) divisible into *Stadt* and *Land*, urban and rural (one-third of the population live in the latter). Then, upward, the *Kreis* (equivalent roughly to county in England and the U.S.); above this again, the *Regierungsbezirk* (government district), a unit of central government control and police authority; and above, the *Provinz* (only in Prussia, which was disintegrated after World War II).

There are also numerous joint authorities for roads, schools, health, fire, agriculture, water, gas and electricity. The *Gemeinden* exhibit an enormous diversity of area and population. There are *Stadtkreis* and *Landkreis*; the former, where the population is above 25,000, is a city-county (like the English county borough). There is a rather special kind of holding company local authority, the *Amt*, to administer the common affairs of some contiguous villages while they still remain separate *Gemeinden*. More important area changes require parliamentary statute. Free agreement among the local authorities is practically unobtainable. The impetus toward city-countyship is enormous, for the same reasons as toward county boroughship in England. The Nazi municipal order of 1935 gave wide powers of areal change to the national cabinet.

Whereas all other nations combine most local government functions in single compendious areas, the U.S. has distributed many of these, especially education, health and parks, to special authorities. The area structure of local government in the U.S. has a different foundation according to the historic settlements. In the south and south central region the chief unit is the county (or parish in Louisiana); in the north central, the combined county and township; in New England, the town. The constitution of Alaska vests powers of local government in boroughs and cities. In some states, the people of each county may vote to divide the county into townships. In the 1960s there were approximately 3,000 counties and parishes. The smallest had 208 inhabitants, the largest (Los Angeles county, Calif.) more than 6,000,000. The average was 45,000.

Some of the functions such as taxation, judicial registrations and records, first instance judicial action through the county court and justices of the peace and elections are those of modern central rather than local authorities. Others such as education, highways and bridges, social welfare, poor law, hospitals, pensions, health, and defectives and delinquents are serious burdens on nonpopulous areas. Services remain inefficient or the state takes them over, for consolidation of counties is resisted. Some unions of counties have been formed for hospital and poorhouse administration.

Inset in the county is the city, with its own powers, and in direct relationship with the state government. Sometimes both city and county conduct for two concentric areas many similar services with substantial duplication of staff and organization. The cities are the areas of the heaviest integration of local government services. As elsewhere, there is antagonism between city and county, and the federal authority after the 1930s became an important direct supporter of city unemployment, public works, municipal utility and housing schemes. Towns, which are mostly but not exclusively semirural communities and are fairly populous in New England, New York, Pennsylvania and the north central states, play the part of the counties elsewhere and have city functions and sometimes city status also. As a part of a township or a county, there are inhabited centres, called villages or boroughs. The state legislature usually requires that such a subdivision reach a certain level of population before it may become self-governing. Area problems in the U.S. revolve around the adjustment of county and city, and the problem of metropolitan areas. Here also, political vested interests and simple inertia obstruct modernization by the legislatures.

In the Soviet Union the tsarist areas were replaced by territories, regions and *oblasts*, and include districts (*raion*), cities and boroughs (within cities), settlements and villages. At the top of the pyramid is the supreme soviet of the union republic. The upward relationship may be expressed in Lenin's phrase, "centralized supervision with decentralized activity." Within the cities of 100,000 there are subordinate soviets, of which Moscow has 240. Cities of more than 50,000 and especially important places of lesser population receive a status independent of the *raion* hierarchy and are directly subordinate to the republics. Attached to these cities are surrounding rural settlements which fully participate in the city government but possess village soviets also. The republics enact these connections. A marked reduction of the local middle units of government has occurred since 1917.

Powers.—Broadly speaking, the large geographic units in the hierarchy are concerned with financial and administrative supervision of the primary units, the provision of environmental and institutional and police services, and technical and financial supplements and assistance to the smaller authorities. Authority to act is always a combination of specific grant and general grant by the central authority, sometimes with modifications by the administrative supervisory authorities and the courts.

In Great Britain, the specific grant of power is supreme. Powers are granted to the various classes of local authorities by general statutes, and by special addition to individual local authorities in private or local acts. The powers granted by general statute are either permissive; e.g., libraries, or compulsory; e.g., education or hospitals for infectious disease. The powers appear in the great statutes such as the Municipal Corporations act (1835) and the Local Government act (1933), which may be termed constitutive, or in acts on education or police, which may be called functional. The permissive powers offer remarkably wide opportunities for initiative. Where local authorities petition parliament for private acts, they may obtain the opportunity to pioneer, if they prove desirability and financial capacity, and successful administration is sometimes followed by granting extension of powers to all authorities. The merit of the system of specific grants is the addition of the good sense of the central authority to that of the local electorate in determining new services, which necessarily involve controls over local citizens and power to raise taxes. All the bigger authorities have a rather restricted power to make by-laws.

In France and the Federal Republic of Germany the municipalities are given by the constituent statutes a general authority to do whatever is proper for the good of the municipality. But what is proper is legally challengeable by citizens, and administratively by the central departments. Initiative is limited by the claims of other communities, private enterprise and the state organs. Also there are functions obligatory on the local units—from 50% to 80% measured in expenditures—prior to the discretionary ones. The approval of the higher administrative authorities and the administrative courts is needed for utilities so that not very much is accomplished. In Germany from 1890 on, the cities proceeded remarkably with municipal enterprise. Despite specific grant in Great Britain, that country was probably unmatched in the extent of municipal management of utilities until the nationalization referred to.

In the United States counties have specific grants. The cities receive their powers in the charters. These are stated specifically, but in broad outline, while additional powers are granted from time to time.

The Russian republic constitution grants to all local authorities the power to "direct the cultural, political and economic construction of their respective territories," and the power to make decrees within the laws of the union and the republic, and then specifies further by requiring the local soviets to set up executive departments. The local soviets are generically unbounded in these powers, but in all are minutely subject to central plans.

The powers actually exercised by modern local authorities in the middle of the 20th century were immensely in advance of anything known in the early 19th century. Then the main services were

highways, police, public assistance, the removal of health nuisances, perhaps fire fighting, perhaps infectious diseases, here and there public education. In Great Britain about 80% of the work of the local authorities came to include the modern social services and municipal enterprise: in other countries the situation was similar or was becoming so. The powers usually exercised by local authorities included education up to high school and technical schools (in the U.S. sometimes colleges and universities); public health in a variety of environmental and personal services; mental diseases; housing provision and management; town planning, zoning, building regulation; poor relief and, in the U.S., local administration of social security services; small holdings, allotments; parks and open spaces and playgrounds; agricultural improvement and land drainage, agricultural education; roads and bridges; streets; public lighting; fire fighting; police (larger authorities only, except in the U.S.); lower instance justice; foods and drugs, and weights and measures inspection; enterprises of gas, electric power, public transportation, water supply (in the German cities, laundries, milk supply, bakeries, theatres, concerts); and land purchase. In the soviet system, the local soviets are subordinate units in the vast industrial and agricultural plans, the local soviets in their turn bringing the collective farms under especially stringent tutelage.

The tendency was toward more local powers, because all government was getting more power, but the development of planned economy, social security, public medical care and civil defense transferred the decision making and higher direction to the bigger authorities, though not excluding the smaller from direct local execution with much latitude therein.

Finance and Local Freedom.—The finances of local authorities have a bearing upon their administrative freedom. Two of the crucial points are: (1) their authority to raise revenue and (2) freedom of budget making.

1. Revenue may be raised by authority of general codes or special statutes. In France, tax freedom is limited by the need of superior authorization of the budget. In the Soviet Union the fully planned economy limits tax freedom, and the constitution itself requires that all local soviet budgets fit into, and be previously sanctioned by, the budgets of the republics.

In Great Britain and the United States, the principal financial limitations are on loans. In the former, previous administrative authority is required; in some states of the United States, limitations of total indebtedness are prescribed. German cities have wide financial freedom, though loans require higher sanction.

2. Local budgets need no superior approval, either in Great Britain or the U.S. In France, the *maire's* and the *préfet's* approval is required and they may require balancing and inscribe mandatory expenditures or invalidate optional expenditures. The Federal Republic of Germany also requires compulsory appropriations when higher authorities consider that provision is inadequate. In the soviet government, the higher authorities exercise penetrating control over revenue raising, appropriations and budgets.

In Great Britain grants-in-aid from the central authority play a very important financial and administrative role; in the U.S., rather less so, but with growing importance. In France and Germany the sharing of taxes with the central government was more important relatively than grants-in-aid. Grants and the form they take are instruments of superior control, regulation and stimulation. In the Soviet Union, the local soviets draw revenue from the communized property allotted to them as public corporations. They may add to the state turnover tax a percentage sanctioned by the superior local authorities to meet expenditure on functions authorized by them, these higher levels controlling their budgets in minute detail.

Organization.—The local government statutes of all the countries concerned prescribe certain kinds of internal organization—mayor, chairman, aldermen, committees and commissions for executive and legislative operations and management of the permanent staffs. Some significant differences deserve notice. The English form of internal organization is that of all-party committees each in touch with the technical or expert directors of departments. The only co-ordinator is the town or county clerk, in collaboration with the mayor or chairman who is annually elected

from the council. The committees have a very large degree of delegated authority, subject to ratification by the council, but not to tax, raise a loan or make a contract. The French system has the centrally appointed *préfet* dominating the *département* council; in the municipalities, the council elects the mayor. The former works with a secretary-general appointed by the central government. A small standing committee of the council, called the *commission départementale*, controls and co-operates with the *préfet* as regards the budget, the audit of expenditures and civic property. It has further delegated powers from the council, but not to tax or spend. The *maire* is served by a number of *adjoints* chosen from the council by seniority and value of services to the commune, who supervise the various departments of municipal activity, and jointly act as an advisory body to the *maire* and draw up the budget.

In the German system, in the county, the chief executive is the *Landrat*, appointed by the central government, who co-operates with a small executive committee of the county council. In the rural communes, a chairman or *Bürgermeister* is elected by the council, and works with assistants or aldermen chosen by the councilors. The various states of Germany have diverse practices. In some there is a kind of bicameral system, called *Magistrat*. The elected council co-operates with the *Magistrat*, which is an administrative board of officials and some laymen chosen by the council led by the *Bürgermeister*, the principal official—but since World War II, the *Magistrat's* power has been reduced to a suspensive veto only. In the *stadtrat* system, the elected council is singly the supreme authority, and works with an elected first *Bürgermeister*, but has an appointed second *Bürgermeister* as its administrative officer. The system prevails in Bavaria. There is also the *bürgermeister* system, as in North Rhine-Westphalia, where the elected council has supreme authority, chooses its *Bürgermeister* who has a suspensive veto over the council's resolutions, and then a professional *Stadtdirektor* like a U.S. city manager, appointed for 12 years, as chief of administration.

In the U.S. system there are four conspicuous forms of organization: the town meeting, the commission system, the council and mayor system, the city manager system. In the first, the meeting of taxpayers settles main lines of policy, chooses selectmen and officials, accepts the budget, controls administration and checks expenditures. It is unwieldy for large cities. These then may be administered by a small number of commissioners elected simultaneously as heads of the executive departments and are collectively the general government of the city. The system encourages disintegration of leadership, and is on the decline. Elsewhere a council and some officials and the mayor are elected at the same time. There is a separation of legislative and executive authority at an enormous cost of energy which produces some but not all of the desirable progress.

From the mid-1910s to the early 1960s the city manager system developed strongly until it applied to about 1,275 cities, towns and counties, a great part of the increase coming after World War II. The elected council appoints an executive, a career official to energize, manage and appoint the officials, and to co-ordinate and make the budget—this official operating side by side with the elected mayor. The city manager is no tsar; he serves the council, and the local statutes give him a strong status, but it cannot be stronger than the authority of the council. His indefinite tenure may be cut short. (See CITY MANAGER.) In general, the United States system is distinguished by its use of the initiative and referendum, especially necessary in the commission form.

In the soviet system the local soviet elects a presidium or executive committee from its members. This body is the formulator of policy as well as the executive—the council discusses and ratifies. The presidium is assisted by experts or interested citizens co-opted onto its committees. This practice of co-option was originated in Britain; many countries now practice it. The Soviet Union and some German states require of councilors an annual or semiannual "open house" to the public. Soviet councilors may be recalled by dissatisfied constituents, but this happens very rarely.

During the 19th century, local administration had little power

and was a field of much unpaid service, patronage and spoils, but the merit and career system advanced. Appointments are made by the chief executive officials in the French and German systems, but according to general statutory qualifications and tests. In England, the central government by law prescribes the basic qualifications of some officials—the medical officer of health, the sanitary inspector, the police, teachers, etc., but appointment and management are fully by the local authorities, though since 1946 a nationwide examination and appointment and salary code has been fashioned and introduced by the local authorities' associations. Some officers have the right of appeal to the central authority against dismissal; e.g., medical officers of health. In practically all large authorities and most small, a career service prevails. In the U.S. it has been estimated that civil service appointments total about 55% in the cities, and about 30% in the counties.

Central Control.—The intensity and techniques of administrative control by the central authorities are indexes of the limitation of local self-government. General tutelage, characteristic of France, Germany and the U.S.S.R., operates through continuous organized hierarchical vigilance and intervention downward from the designated central department to the lower levels of local authorities. In Great Britain statutory rules and orders made by the designated central department administering the statutes relating to local functions, advice, admonition, exhortation, preparation of scientific memoranda and reports of experience are parts of tutelage.

The sanction of administrative schemes is a more severe and specific form of central control: it is strong though not fully comprehensive in England. In France and Germany it is more comprehensive and in the Soviet Union it is total through the agencies already mentioned. In the U.S., higher sanction is rare and applies to welfare and public works schemes assisted by the federal authority, and occasionally to highways, education and hospitals financially assisted by the states.

Submission of periodic reports is universal, but applies in the U.S. mainly to the services already mentioned, and in some states to the local accounts. The growth of standards, scientific definition, forms and statistical analysis after the middle of the 19th century was a powerful instrument of centralization, since both local and central officials can be of one mind in reporting and deciding answers to governmental problems.

Audit of local accounts by central officials is severe and important in England; in France and Germany it is hierarchical, going finally in each case to the special courts of accounts. In the U.S., though accounting and fiscal practices are in some cases state regulated and the election of local auditors required, external and compulsory audit hardly exists. Inspection by central officers is the most distinctive feature of the English system, having been carried to a highly comprehensive and efficient stage in which the inspectors are not only investigating and enforcement-assisting agents, but counselors on good practices, and flexible intermediaries between the capital and the localities. There is also inspection in the French and German systems, but it is overshadowed by the centralist form of the system. In the U.S. the small amount of inspection is related only to the services already mentioned. Action in default is very limited and rare in England; practically nonexistent in the U.S.; has been practised in Germany; is unnecessary in France because previous sanction (*tutelle*) and obligatory expenditure prevent local default. The central power to remove the French *maire* or the *préfet* may be borne in mind. Stern hierarchical and party and newspaper criticism is designed to obviate local default in the U.S.S.R., but self-seeking and inefficiency often produce defects punished by recall.

Finally, personnel rules are laid down by the English central authority for some key officials; the office of *préfet* in France in 1945 was made a career service, intermingled with service in the central administration, following successful graduation from the government-sponsored École Nationale d'Administration. A few states in the U.S. exert some small influence on the civil service conditions of the localities; in Russia, the local soviets use the graduates of technical schools as screened by the Communist party. The payment or withholding of grants constitutes a sanction of

these various instruments of central control. This is especially strong though flexible in England; much less so in France and Germany; firm over its small field in the U.S.; while the soviet system relies on other incentives, mainly fear or revolutionary zeal. In France and Germany, local authorities are subject to control by appeal to the administrative courts; in Britain, to the ordinary courts; in the U.S.S.R. no such appeals to a judiciary are entertainable, and the only recourse is to the hierarchy or the prosecutor's office.

Variety and development are marks of contemporary local government. Larger areas for local government with more central direction are on the way. Many new functions are impending. The feeling of attachment to the old areas is a retarding factor; the recognition that the small area has continuous human values and certain long-run technical advantages in assisting consumer control over administrators will force centralization to assume accommodating forms. The great associations of municipalities and the professional officials already contribute considerably to the efficiency of the localities, and their services are destined to be even more valuable as moderators of centralization. Yet the forces of modern large-scale economic organization and civil defense weaken the scope and independence of local self-government.

LOCAL OPTION. The term local option has been used to refer to a variety of permissive laws effective locally only after affirmative vote by the local electorate; for example, laws allowing political subdivisions a choice between forms of government or methods of representation.

It has particular significance, however, in alcoholic beverage control. In this context local option refers to a liquor control system under which each locality is permitted to vote upon the existence of legal dispensaries within its boundaries.

Early History.—Local option was a natural outgrowth of earlier licensing plans. As early as the 16th century English ale-houses were licensed by the sessions of the peace and in the American colonies, though the licensing authority was first exercised by the governor, the advent of the American Revolution found the tradition of local licensing firmly established. The history of Massachusetts is typical; in 1633 it was provided that none should sell wine or strong water without leave of the governor or deputy governor. In 1645 the licensing authority was shifted to the quarter courts and two years later to the county courts. In 1680 a provision was adopted prohibiting the court from issuing licences without the prior approval of the selectmen of the town in which the licensee sought permission to operate.

These provisions, and similar ones in the other colonies, were directed at policing the propriety and good morals of public houses and were not designed to implement total prohibition. The birth of the vigorous temperance movement of the 19th century coincided, however, with a trend toward the popular election of the county courts and their successors, and it was natural that the pressures of the early prohibition movement should be focused upon these officers. The reasoning of the prohibitionists ran thus: if the local governing body can deny one licence, it can deny all licences and local prohibition will be a reality. The problem became one of electing officials committed to a policy of "no licence."

The "no licence" movement met with several legal and practical obstacles. In 1844 the supreme court of North Carolina held that the discretion vested in the county court was not broad enough to sustain a policy of denying all applicants for retail liquor licences as "injurious to good morals" (*Attorney General v. Justices of Guilford*, 27 N.C. 315). In those states in which no legal objection was raised, although results in the rural areas were gratifying to the prohibitionists, temperance leaders were generally disappointed at their inability to carry the larger cities and towns and turned their attention to pressure for state-wide prohibition.

Local option in the sense of direct vote by locality on the question of prohibition came into vogue as a grudging concession to these pressures. The democratic flavour of local choice was never accepted by temperance workers. Theirs was a moral fight with a single ultimate goal. The *Cyclopedia of Temperance and Prohibition*, p. 394 (New York, 1881) frames the issue with candour: "By far the greatest of local option's defects is its rotten basis as to morals, where its presumptuous elective system appears most audacious. With its majority rule set up as an origin of right, the results are most destructive to all proper conceptions of divine law." Within this ultimate objective, however, prohibitionists were willing to carry on their fight at all levels, adhering to the slogan provided by Judge Robert Pitman of Massachusetts: "Wherever license prevails, wrest every inch of territory you can for prohibition; wherever prohibition prevails, never surrender an inch to license, except from dire necessity" (*Alcohol and the State*, New York, 1877). By 1906, 30 states were operating under local option and more than half of all the counties, 60% of all the incorporated towns and villages and 70% of all the townships in the United States were dry.

Later History.—Local option in the United States disappeared, of course, with national prohibition. With repeal, though the older system of local licensing generally gave way to some form of central regulation, typically U.S. states returned to local option.

The plans varied greatly both as to voting unit and as to the alternatives placed before the electorate. In the typical state, cities and counties (incorporated towns often voting separately) may choose between total prohibition, sale of wine and malt beverages, package sale of distilled spirits and sale by the drink. Initiative in such elections is customarily left to petition by a fixed percentage of the qualified electors and elections may be held every year or two years.

In some communities elections may be held in a single precinct constituting at times not more than a few square blocks. Where precinct elections are permitted, however, they are usually considered as a device for protecting residential neighbourhoods from the influx of taverns, rather than an opportunity for an expression of wet or dry sentiment.

By the second half of the century, only two states in the United States still had state-wide prohibition, Mississippi and Oklahoma: in both of these dry states, however, alcoholic beverages could be sold providing they did not contain more than 4% (Mississippi) or 3.2% (Oklahoma) of alcohol by weight. In 1959 the constitution and statutes of Oklahoma were amended to provide for licensed sale. Mississippi, which had been the first state to ratify the national prohibition amendment in 1919, became the last to repeal state prohibition, in 1966.

There were provisions for local option in approximately three-fourths of the states in the 1960s.

Local Option in the United Kingdom.—The principle of local option is embodied in s. 6 of the Licensing act, 1961. This provides for the holding of a poll at requisition in any county or county borough in Wales or Monmouthshire by not less than 500 local government electors to determine whether or not s. 111 of the Licensing act, 1953, shall apply to the area in question. This section of the 1953 Licensing act directs in effect that there shall be no opening of licensed premises in Wales and Monmouthshire on any Sunday. As a result of polls held in accordance with the 1961 act, all four county boroughs, Swansea, Newport, Cardiff and Merthyr, declared in favour of Sunday opening. Of the counties five declared in favour of opening and eight against.

(J. D. Ls.; X)

LOCARNO (Ger. LUGGARUS), a town in Ticino canton, Switzerland, is picturesquely situated at the northern end of Lake Maggiore near the mouth of the Maggia river, 18 km. (11 mi.) W. of Bellinzona by rail. Pop. (1960) 10,155. Favoured by a warm Mediterranean climate, Locarno is an Italianate city, chiefly noted as a health and tourist resort. It contains numerous hotels and other tourist facilities, and the nearby shores of the lake are studded with villas. The city's gardens are famous. The principal shopping centre is in the arcaded Piazza Grande. In the Pretorio or law court the pact of Locarno was signed in 1925 (see LOCARNO, PACT).

OF). On a rock above the town, in the suburb of Orselina, is the convent church of Madonna del Sasso, containing a "Flight Into Egypt" by Bramantino and an "Entombment" by Antonio Ciseri. A magnificent view of the city and of Lake Maggiore can be obtained from its terrace. Locarno was taken by the Swiss from Milan in 1512. From 1815 to 1878 it was one of the three capitals of Ticino canton.

LOCARNO, PACT OF, a series of agreements made in 1925 whereby Germany, Belgium, France, Great Britain and Italy mutually guaranteed the peace in western Europe, and Germany undertook to arbitrate disputes with Belgium, France, Czechoslovakia and Poland. The treaties were initialed at Locarno, Switz., on Oct. 16 and signed in London on Dec. 1.

The pact was significant because it marked a break from the atmosphere of World War I, and former enemies committed themselves to a peaceful policy among themselves. The pact was, in a sense, a substitute for the Geneva protocol negotiated by the League of Nations in 1924 but never ratified.

The agreements consisted of (1) a treaty of mutual guarantee between Germany, Belgium, France, Great Britain and Italy; (2) arbitration agreements between Germany and Belgium and Germany and France; (3) a note from the former Allies to Germany explaining the use of sanctions against a covenant-breaking state as outlined in art. 16 of the League of Nations covenant; (4) treaties of guarantee between France and Poland and France and Czechoslovakia.

The treaty of guarantee provided that the German-Belgian and Franco-German frontiers as fixed by the treaty of Versailles (*q.v.*) were inviolable; that Germany, Belgium and France would never attack, invade or wage war against each other except in "legitimate defense" or in consequence of a League of Nations obligation; that they would settle their disputes by pacific means; and that in case of an alleged breach of these undertakings, the signatories would come to the defense of the party adjudged by the League to be the party attacked and also in case of a "flagrant violation." The treaties between France and Poland or Czechoslovakia provided for mutual support against unprovoked attack.

To allay Soviet suspicions, Germany in April 1926 concluded a neutrality pact with the Soviet Union and reaffirmed the treaty of Rapallo (*q.v.*), but this did not prevent Germany from joining the League in Sept. 1926. A further consequence of the pact was the evacuation of the Rhineland in 1930 five years ahead of schedule.

The clear meaning of Locarno was that Germany renounced the use of force to change its western frontiers, but agreed only to arbitration as regards its eastern frontiers, and that Great Britain promised to defend Belgium or France but not Poland and Czechoslovakia.

In March 1936 Germany sent troops into the Rhineland, which had been demilitarized by the treaty of Versailles, declaring that the situation envisaged at Locarno had been changed by the Franco-Soviet alliance of 1935. France regarded the German move as a "flagrant violation" of Locarno, but Great Britain declined to do so, and no action was taken. Germany made no effort to arbitrate its dispute with Czechoslovakia in 1938 or with Poland in 1939.

LOCATELLI, PIETRO (1695-1764), Italian violinist and composer, was born at Bergamo on Sept. 3, 1695. A pupil of Corelli, Locatelli was the first of the great violinists who practised virtuosity for virtuosity's sake, thereby extending the vocabulary of the instrument. Some of the *bravura* effects in his studies and caprices, which anticipate those of Paganini in their concentration on technical feats, overstep the legitimate bounds of music. But these are ostensibly exercises, and in his sonatas and concertos, of which he composed several sets, Locatelli proves himself to be a serious musician capable of elegant and expressive melody. He died on March 30, 1764, at Amsterdam, where he had settled about 1721 and where he gave regular public concerts. (Dy. H.)

LOCH, HENRY BROUGHAM LOCH, 1st BARON (1827-1900), British soldier and colonial governor, chiefly remembered as governor of the Cape colony and high commissioner in South Africa in the period before the Jameson raid (1895). Loch was born on May 23, 1827, the son of James Loch, a Midlothian economist and estate manager. After a brief period as midshipman in the Royal Navy he served in the army in India between 1845 and 1853. When the Crimean War broke out Loch was sent to Bulgaria to help raise an irregular Turkish cavalry force. He accompanied the earl of Elgin's special embassy to China (1857-58) and was attached to the headquarters of the commander in chief during operations in the second Chinese War. While in China again in 1860, as secretary to Elgin's second embassy, he was captured by the Chinese when negotiating under a flag of truce and during two or three weeks in prison was most cruelly treated. Loch's appointments after 1860 were in the civil rather than the military sphere. After a brief period as private secretary to Sir George Grey, home secretary, he became lieutenant governor of the Isle of Man in 1863, for the next 19 years earning the devotion of Manxmen for his sympathetic administration of the island. Knighted in 1880, he was appointed governor of Victoria, Austr., in 1884.

In 1889 Loch was sent to the Cape to succeed Sir Hercules Robinson. He believed in vigorous imperial rule in all its plenitude, and, as high commissioner, his attention was inevitably directed mainly toward the Transvaal where President Kruger's policy was threatening British paramountcy in South Africa. Attempts on the part of the colonial office to act indirectly through the Cape parliament having failed, Loch wanted the imperial government to assert itself much more directly to maintain British supremacy in South Africa. He was also dubious about the wisdom of entrusting British expansion in southern Africa to a group of financiers such as the British South Africa company; and he only reluctantly agreed to the use of British forces by the company in the Matabele War of 1893. Sir Henry was inevitably involved with the grievances of the "Uitlanders," British subjects resident in the Transvaal who were suffering a number of serious disabilities under the Kruger regime. He paid official visits to the Transvaal in 1893 and 1894, his enthusiastic reception on each occasion leading him to underestimate the support which existed for President Kruger, and to exaggerate the ease with which the republic might be obtained for Britain as a prelude to South African federation under the Union Jack. After his first visit he decided to intervene should disturbances occur in the Transvaal, and he evolved the "Loch Plan" for the rapid use of imperial police from the Bechuanaland border, should the opportunity occur, a scheme which, with the imperial factor eliminated from it, Rhodes seems eagerly to have adopted after the return of Loch to England in April 1895, at the end of his term.

Created Baron Loch of Drylaw in the peerage of the United Kingdom (1895), Loch felt obliged to defend himself in the house of lords on May 1, 1896, after the Jameson raid, against press allegations that he had promised the reform committee in Johannesburg armed intervention if insurrection occurred there. Modern South African historians find his explanations not wholly convincing. After the outbreak of the South African War in 1899, Lord Loch raised in England the mounted volunteer force known as "Loch's Horse." He died in London on June 20, 1900. (L. M. Y.)

LOCHABER, a district at the "mouth of the lochs" of southern Inverness-shire, Scot., stretching approximately from Loch Linnhe to Glen Spean and Loch Lochy. The scenery, wild and beautiful, includes Ben Nevis (*q.v.*), through which a 15-mi. tunnel is part of the Lochaber hydroelectric scheme, designed to make use of a catchment area of 303 sq.mi. The powerhouse is close to Fort William.

LOCHES, a town in France, capital of an *arrondissement* of Tours, in the *département* of Indre-et-Loire, 25 mi. S.E. of Tours by road, on the left bank of the Indre river. Pop. (1962) 4,526. Loches (the Roman *Leucae*) grew up around a monastery founded about 500 A.D. by St. Ours. It belonged to the counts of Anjou from 886 until it was seized from King John of England by Philip

Augustus. From the middle of the 13th century until after the time of Charles IX the castle was a residence of the kings of France.

The picturesque town lies at the foot of the rock on which stands the castle of the Anjou family; the castle is surrounded by an outer wall and consists of the old collegiate church of St. Ours, the royal lodge and the donjon. The church of St. Ours (10th, 12th centuries) has huge stone pyramids surmounting the nave and a beautifully carved west door. The royal lodge, built by Charles VII, contains the tomb of Agnès Sorel, mistress of Charles VII, and the oratory of Anne of Brittany. Besides the ruined keep, the donjon includes the Martelet, celebrated as the prison of Ludovico Sforza, duke of Milan, who died there, and the Tour Ronde, built by Louis XI and which once contained the famous iron cages for the confinement of state prisoners. After 1955 restoration work on both the donjon and the royal lodge was carried on.

LOCHGILPHEAD, a small burgh of Argyll, Scot., lies at the head of Loch Gilp and near the eastern entrance to the Crinan canal, 37 mi. S. of Oban by road. Pop. (1961) 1,208. It is the seat of a county court and the administrative centre for the district of Mid-Argyll. Until the disappearance of the herring from the loch, which is a western inlet of Loch Fyne, the town had a flourishing fishing industry. It is now a tourist resort.

LOCHMABEN, a royal and small burgh of Dumfriesshire, Scot., 8½ mi. N.E. of Dumfries by road. Pop. (1961) 1,280. It is a delightfully situated holiday resort in Annandale, with several lakes and the Waters of Ae, Kinnel and Dryfe in the neighbourhood. The town's charter, originally granted by Robert Bruce, was ratified in 1612 by James VI (James I of England). In the parish church is a bell said to have been presented to the original kirk by Bruce, whose statue stands in front of the town hall. At the southern end of Castle Loch are the ruins of Lochmaben castle, dating from the 13th century, where local tradition declares that Bruce was born. He exempted his followers in the district from feudal service and their descendants—the "kindly tenants of Lochmaben"—were confirmed in their tenure by the court of session in 1824. The Bruces had been closely associated with Lochmaben since David I granted Annandale to the second Robert Bruce.

The Lochmaben vendace, a small kind of whitefish, is found only in a few small lakes round Lochmaben. It is captured in fine nets and is considered a delicacy. Lochmaben is famous for curling, and a team entirely composed of shoemakers (souters) who held their own against all comers once added the phrase "to souther" to the vocabulary of the sport, the word indicating a match in which the winners scored "game" to their opponents' "love."

LOCHNER, STEPHAN (c. 1400–1451), one of the most attractive of German painters, who is often compared to Fra Angelico and is considered to have brought the Cologne school to its peak of achievement, was born about 1400 in Meersburg. His name has come down to us through Albrecht Dürer's diary of his journey through the Netherlands, in which he remarks that at Cologne he has had Master Stephan's tablets unlocked. By this he means the great, well-preserved triptych which presents the "Adoration of the Magi" and, on the wings, SS. Ursula and Gereon and their followers—that is, the patrons of Cologne. Formerly in the chapel of the town hall, it is now in the cathedral. In this work Lochner fills out the idealism of the older painters of the Cologne school with a seemingly inexhaustible wealth of naturalistic observation in the figures and composition, while the splendid plasticity of the draperies lends them a monumental dignity.

Lochner came to Cologne about 1430; he must previously have been in the Netherlands. The earliest work he did in Cologne was an altarpiece for the church of St. Lawrence. Only the centre-piece with the "Last Judgment" is now in Cologne (Wallraf-Richartz museum); the inner sides of the wings with the martyrdom of the apostles are in the Städel in Frankfurt, while the outer sides with "standing saints" are in the Pinakothek in Munich. The disconcertingly impressive posing of the saints and of the damned, with their back views and half-inducted profiles, the precise representation of the overturned tombstones and of the plants—this realistic vision came to Lochner through suggestions from the

circle of the Limburg brothers. But his eye would never have moved beyond individual things if he had not attempted in the central picture to bind the various themes into a unity. In the light and delicate treatment of the objects and the people the work is already masterly.

A little later Lochner painted a small panel with "St. Jerome Meditating in his Study," a "Crucifixion with Saints" (Nürnberg), and for St. Katharine's, the church of the Teutonic order, a two-winged altarpiece painted on both sides, each with three saints. These are in the National gallery in London and the museum in Cologne. In the later 1430s Lochner must have been in the Netherlands again, where he encountered the art of Van Eyck. The first work to reflect this influence is the "Madonna with the Violets," which was done for Elisabeth von Reichenstein, the abbess of the St. Cecilia chapter, about 1443. Van Eyck's influence is noticeable above all, however, in Lochner's chief work, the great town hall altarpiece described above, and in a charming little "Nativity." In 1447 he became a member of the town council, and from the same year dates the splendid "Presentation in the Temple" (Darmstadt museum), which was originally in St. Katharine's. The exquisite "Madonna in the Rose Bower" (Cologne museum) was painted soon afterward.

In 1451 Lochner died, probably being carried off by the plague. He had come to Cologne from afar, but he was in the deepest sense closely related to the city's genius. He became one of the greatest of Cologne's painters, subduing the naturalism of his early works and building up colour and form into a festal solemnity of representation. Lochner must have had a highly productive workshop during all his years in Cologne. From it originated such works as the Gulbenkian collection's "Presentation in the Temple" (1445), Cologne museum's "Madonna in the Garden of Paradise With Saints," two altarpiece wings with St. John and Mary Magdalene now in the Pannwitz collection, and an "Adoration of the Christ Child" painted on canvas in the Diocesan museum in Cologne. Book illumination was also done in the workshop.

LOCK, a device for securing a door, drawers or a box with an inside bolt which cannot be moved except by a key, or by setting a handle or wheel in a way known only to one or a few persons.

Ancient History.—The earliest form of lock appears to be that found in the ruins of the palace of Khorsabad near Nineveh, about 4,000 years old. It is of wood, and the bolt is held in the closed position by several loose wooden pins which fit into holes in it. A long wooden key can be inserted into a slot in the bolt. This key also has pins in it and these pins raise the loose wooden pins to the height that will allow the bolt to be withdrawn (Fig. 1). This type of lock was known to the ancient Egyptians and had

FIG. 1.—ANCIENT EGYPTIAN LOCK

been found in Japan, in the Faeroe Islands and in Norway. The long keys were carried on the shoulder and account for the verse in Isaiah, xxii, 22, "And I will place on his shoulder the key of the house of David." The principle of the loose locking pins is later to be found in the Yale lock.

The Romans invented metal locks and keys, and the system of security provided by wards. This system was, for hundreds of years, the only method of ensuring that only the right key would rotate in the keyhole (fig. 2). The wards are projections around the keyhole (inside the lock) which make it impossible for a plain key to be turned in it. If, however, the key has slots cut in it which correspond with the projections, the slots clear the projections, the key can be turned and the bolt is thrown back. Throughout the centuries immense ingenuity was exercised by locksmiths in the design of the wards, and consequently some keys are very complicated.

FIG. 2.—WARDER LOCK AND KEY

All the same it was not difficult to make an instrument which could be turned in spite of the wards, to achieve what is known as "picking" a lock. The Romans also developed very small keys which were often designed to be worn as finger rings (fig. 3), and they also introduced the padlock (though the Chinese may have invented this independently), which is found throughout the near and the far east.

FIG. 3.—ROMAN FINGER RING KEY

From the Middle Ages to the 18th Century.—The locksmiths of the middle ages, especially in Germany, excelled in the workmanship of their products. The keys and moving parts were beautifully finished, the wards were of extreme complexity and ingenuity, and every art of the designer was lavished on the exteriors (fig. 4). This practice was continued by the French into the 18th century, as shown in the illustrations and descriptions of H. L. Duhamel du Monceau's *Description des Arts et Métiers. Art du Serrurier* (Paris, 1767). Nevertheless, in spite of all this attention and the great need in those lawless days for a secure fastening, little progress was made in the mechanism of the lock; elaborate warding of the key and concealment of the keyhole remained the chief safeguards.

Mechanical Improvements.—In 1778 Robert Barron, in England, patented and manufactured a double-action tumbler lock, which was the first of a series of great advances in lockmaking.

FIG. 4.—THE WROUGHT-IRON BEDDINGTON LOCK, PROBABLY MADE BY HENRY ROMAINE, LOCKMAKER TO HENRY VIII. IN THE VICTORIA AND ALBERT MUSEUM, LONDON

A tumbler (later known in England as a lever and in the U.S. as a lever tumbler) is a pawl which engages the bolt of the lock and makes it impossible for it to be withdrawn until the tumbler is raised. However, as almost any key which the wards allow to be turned will raise the tumbler, it is of little value in its simple form. In Barron's lock there were two tumblers engaging in a slot in the bolt. As shown in the illustration (fig. 5), the key had to lift each tumbler to exactly the right height before the lock would open. This was an enormous improvement in security and in the 1960s it remained the basic principle of all lever locks.

FIG. 5.—BARRON'S TUMBLER LOCK, 1778

In 1818 Jeremiah Chubb improved on the Barron lock by adding a device called a detector which not only made the lock more difficult to pick but also indicated that an attempt had been made to do so. This detector is a lever placed among the other levers so that if any one of them is raised too high (by an incorrect key or an attempt to pick the lock), a spring will maintain it in the raised position. This prevents the bolt from being thrown and also indicates that the lock has been tampered with.

Very important in the progress of lock design is Joseph Bramah's lock, patented in England in 1784 (fig. 6). For more than 50 years it was the most difficult of all locks to pick and in the 1960s many were still in use. It is operated by a cylindrical key in the end of which fine slots are cut. The key, whose smallness is one of the assets of the lock, is pressed into the keyhole and forces thin metal plates down varying distances, thereby clearing a slot and allowing the key to turn.

The machines made by Bramah (*q.v.*) for the fast and accurate manufacture of his locks were probably the first mass-production machinery in the world. Lockmaking reached its heyday in 1851. At that time, manufacturers demonstrated the safety of their locks by challenging others in the trade to pick them, and it was in that year that the Bramah lock was first picked, by an American, A. C. Hobbs.

In 1848 Linus Yale of Middletown, Conn., patented his first pin tumbler lock, employing the same principle as the ancient Egyptian lock. His son, Linus Yale, Jr., improved on this in the 1860s and evolved the familiar Yale cylinder lock (fig. 7) with its thin, convenient key capable of many thousands of variations. The key is made in a number of different cross sections so that only a particular variety of key will fit into a particular keyhole; this, in effect, is a form of ward. The serrations on the edge of the key raise pin tumblers to exactly the correct height, allowing the cylinder of the lock to revolve and withdraw the bolt. Although not impossible to pick, these locks are convenient and compact and offer a reasonable degree of security. In the 1960s they were the most usual form of fastening for an outside door and were made by locksmiths in all parts of the world, being universally known as Yale locks.

FIG. 6.—BRAMAH'S LOCK, 1784: (TOP) KEY ABOUT TO ENTER; (BOTTOM) KEY ABOUT TO TURN LOCK

ARM WHICH OPERATES BOLT
(WHICH IS NOT SHOWN)

F. P. GILLMAN

FIG. 7.—PRESENT-DAY YALE LOCK PATENTED IN THE 1860S: (TOP) CORRECT KEY LIFTS ALL PINS TO PROPER HEIGHT SO KEY CAN BE TURNED; (BOTTOM) WRONG KEY LIFTS PINS TO INCORRECT HEIGHT SO LOCK WILL NOT OPEN

into which an explosive charge can be inserted. The security of this lock depends on the unlikelihood of anyone choosing the right combination by accident and the impossibility of trying all the combinations; for example, in a simple safe lock with four rings and 100 numbers on the dial (*i.e.*, 100 positions for each ring) there are 100,000,000 combinations, of which only one will open the lock. Figure 9 shows how the single knob can set all the wheels; in this case the lock has three rings, giving 1,000,000 possible combinations. Suppose that the combination is 48, 15 and 90. The knob is turned counterclockwise until the 48 comes opposite the arrow for the fourth time, a process which ensures that there is no play between the other wheels. The slot on the first wheel (on the left in the diagram) is then in the correct position for opening and it will not move in subsequent operations. The knob is then turned clockwise until the 15 is opposite the arrow for the third time; this sets the slot of the middle wheel in line with the first. Finally the knob is turned counterclockwise to bring the 90 for the second time to the arrow. All three slots are then in line and another handle can be turned to withdraw the bolts. The

combination can easily be changed from time to time.

Time Locks.—In these locks, a clock inside the safe allows the lock to be opened only after a predetermined number of hours have elapsed. Although the first time lock appears to have been patented as early as 1831 by W. Rutherford in Jedburgh, Scotland, the invention was little used until the 1870s, when an alarming increase in bank robberies in America brought about its reintroduction. These robberies all followed the same pattern: the bandits would kidnap the cashier and force him by torture or threats to give up the key or divulge the combination. However, in 1873 James Sargent of Rochester, N.Y., patented a time lock which ended this form of robbery. The mechanism is placed inside the safe and usually comprises two clocks, for safety, with a five-day running time so that they can be used over weekends and bank holidays. The clocks are set so that the locks may be opened at a specified time, and an indicator shows if the lock is in the locked or unlocked position. Access to vaults and strong rooms is usually controlled by locks requiring two different keys to open the doors, and each key is held by a different official.

Master Keys.—A system incorporating a master key is used when a number of locks, such as those securing bedrooms in a hotel or offices in a building, each has a different key and yet all must be opened by a landlord or caretaker using a single key. Where the only security is by wards, a skeleton key which avoids the wards may be the type of master key chosen. In other cases many methods are employed; for instance, there may be two keyholes (one for the servant key, the other for the master), or two sets of tumblers or levers, or two concentric cylinders in a Yale lock.

Locks and Safes in the Mid-20th Century.—The basic types of lock are the Barron, Bramah, Chubb, Yale and combination locks, but innumerable variations have been made. These include locks which are designed particularly to resist being blown open; locks which shoot or stab intruders or seize their hands; locks whose keys can be altered at will; locks which can be opened or closed by several different keys but can be unlocked only by the particular key which closed them; and so-called "unpickable locks," which are usually devised to prevent the thief from exploring the positions of the lock parts from the keyhole or from sensing with his picking tool slight changes of resistance in the mechanism when pressure is applied to the bolt. Also, electronic devices are used to manipulate combinations or to make it possible to control locks from a distance. However, the importance of security (the degree of difficulty involved in picking a lock) declined greatly after the 1940s, for, except in those thefts which were "inside jobs" and for which keys were available, robbers tended to ignore the lock and to use high explosives to blow open the door of a safe. An attempt to blow up the mechanism of a lock by putting gelignite in the keyhole can be foiled by having a second series of bolts which are not connected to the lock mechanism but which are automatically inserted by springs when an explosion occurs; the safe then cannot be opened except by cutting through the armour. Until recently the plating or hinge of a safe could be burned away by an electric arc or an oxyacetylene flame, though only after many hours' work. In the 1960s the materials used in safe building were so resistant that only prolonged burning by an electric arc whose electrode is supplied with oxygen could make an impression.

LOCKE, DAVID ROSS: see NASBY, PETROLEUM V.

LOCKE, JOHN (1632–1704), English philosopher, the initiator of the Age of Enlightenment and Reason in England and France, an inspirer of the American constitution, and, more than a quarter of a millennium after his death, still a powerful influence on the life and thought of the west, was born at Wrington near Bristol on Aug. 29, 1632. He belonged to a decent and devout

middle-class family, probably Anglicans with Puritan leanings, settled in the Somerset villages near Bristol; his father, John Locke, an attorney, who owned or rented land at Pensford, served for a short time on the Parliamentary side in the Civil War. The father's conduct toward his son was exemplary; as the boy matured he relaxed control and consulted him about his affairs, a course that probably influenced Locke's views on education. In 1647 Locke entered Westminster school. He proceeded to Christ Church, Oxford, in 1652; presumably following the usual arts course, he graduated B.A. in 1656 and M.A. in 1658, and in 1658 was elected a student (equivalent to a fellow in other colleges) of Christ Church.

During the next few years he performed college duties and took pupils. Dissatisfied with the scholastic philosophy still taught in the universities, he was attracted by the scientific studies that flourished in Oxford during the Protectorate, attaching himself to Robert Boyle and applying himself to medicine. From reading Descartes he learned to appreciate philosophy, and he read widely in contemporary English writers. One outcome was his *Essays on the Law of Nature*, written about 1662-63 (in Latin; first published, with English translation, notes, etc., by W. von Leyden, 1954).

In 1661 Locke inherited part of his father's estate, worth, with some additional property, about £60 per annum. He had still to fix on a career. Normally his studentship was not tenable indefinitely unless he took holy orders, which he refused to do. His medical studies brought him the friendship of a doctor, Thomas Sydenham, whose method of treatment, rejection of *a priori* views, and reliance on observation, may have helped Locke to form his philosophical system; but, though he continued his studies, graduating B.M. in 1675 and frequently advising his friends, he was averse to practising medicine. He spent some months in the winter of 1665-66 in Germany at Cleves, as secretary to a diplomatic mission to the elector Frederick William of Brandenburg.

In the summer of 1666 Lord Ashley, the chancellor of the exchequer (Sir Anthony Ashley Cooper, created earl of Shaftesbury in 1672), required some medical attention while visiting Oxford; Locke was introduced by a common friend and immediately won Ashley's friendship. In November he was granted a royal mandate to retain his studentship without further qualification. In 1667 he joined Ashley's household at Exeter house in the Strand in London. He served the family as physician, operating on Ashley in 1668 and attending the birth of the third earl of Shaftesbury in 1671, but was more important as a confidential adviser and secretary. He was concerned in Ashley's colonial ventures and helped him to draft a constitution for the newly established colony of Carolina. While Ashley—now Shaftesbury—was lord chancellor (1672-73) Locke was his secretary for patronage. In 1673-74 Shaftesbury was president and Locke was secretary of the council of trade and plantations.

Partly in response to a controversial pamphlet, Locke wrote in 1660-61 two treatises concerning the powers of the civil magistrate, which stated that, whatever its origin, whether by divine right or by the contract of the members of the community, the magistrate's authority must be supreme; the ruler of the nation must have an absolute and arbitrary power over all indifferent actions; subjects have no right to religious liberty. If these were his views at that time, they had changed radically by 1667, when he wrote an essay on religious toleration: he questions divine right; the magistrate's power is restricted to the preservation of peace among the subjects; everyone is entitled to religious liberty, except when it may endanger the community—an exception especially disqualifying Roman Catholics as they appeared to contemporary Englishmen. Locke was perhaps influenced by Ashley, a champion of civil and religious liberty, who in the constitution of Carolina extended freedom of worship to all comers, atheists alone being inadmissible as colonists.

In London, Locke moved in good intellectual society. He was elected fellow of the Royal society in 1668. At a gathering of some friends in his rooms, probably early in 1671, he writes, when they were discussing a subject not stated:

After we had a while puzzled ourselves, without coming any nearer a resolution of those doubts which perplexed us, it came into my thoughts, that we took a wrong course; and that, before we set ourselves upon enquiries of that nature, it was necessary to examine our own abilities, and see what objects our understandings were or were not fitted to deal with.

This was the starting point of the *Essay Concerning Human Understanding*. Two drafts of it written in 1671 are extant. Locke worked on it, as opportunity offered, during the next 18 years.

By 1675 Shaftesbury had lost all his offices. Locke suffered from asthma. Believing at this time that his ailment was phthisis and hoping to improve his health, he went to France late in the year. He spent his time partly in Montpellier, where there was a good medical school; partly in Paris, where he made friends with several scholars and scientists; partly traveling about France, noting especially the great works of civil engineering, methods of cultivation, and Louis XIV's treatment of his Protestant subjects, whose rights, granted them by the Edict of Nantes, were being diminished legally or by chicanery. So far as is known Locke met neither Malebranche nor the great Antoine Arnauld. While in France he worked on the *Essay* and wrote short essays on various philosophical subjects.

Locke returned to England in 1679, to find Shaftesbury leading the opposition to Charles II in a major political crisis. This had started with the revelation of a fictitious Roman Catholic conspiracy to assassinate Charles II, who would be succeeded by his brother (the future James II), a Roman Catholic; contributory circumstances favoured the acceptance of the revelation. Shaftesbury now proposed the exclusion, by act of parliament, of Roman Catholics from the throne. This raised the issue, whether succession goes by indefeasible hereditary right, and, following on that, whether the king is absolute, with no responsibility to his subjects, or bound by law and obliged to govern in accordance with their wishes. To support the king's side Sir Robert Filmer's *Patriarcha*, a vindication of the divine right of kings written about 40 years earlier, was published in 1680. Locke set out to controvert it, refuting in detail each of Filmer's arguments in turn in a first treatise and describing the foundations of government in a second (for the publication of this work, in Oct. 1689, see below). He also joined with a friend in replying to an Anglican attack on the right of Nonconformists to separate from the Church of England.

The agitation over the Exclusion bill was succeeded in 1681 by a royalist reaction. Charles II wanted to guard against future crises of the kind and to avenge himself for the humiliations that he had undergone. He struck at Shaftesbury and his adherents, who were now called Whigs. Shaftesbury eluded him, but indulged in some wild talk and perhaps projected a rising; he eventually fled to Holland, where he died in 1683. Some of the leading Whigs engaged in a conspiracy, the Rye House plot, which was discovered in June 1683. The treatment of the conspirators, and of other followers of Shaftesbury's who could be associated with them, showed that Charles meant to take full toll. Locke is exceedingly unlikely to have participated in any subversive movement, but his position in royalist Oxford was uncomfortable; as a valetudinarian of timorous character he decided to seek refuge in Holland, going there about Sept. 1683.

In Amsterdam, Locke met a doctor whom he had known in Paris and, through him, Philippus van Limborch, the head of the Remonstrant Church in Amsterdam, a distinguished theologian and an ardent believer in toleration; he became one of Locke's closest friends. He also met Jean Le Clerc, a former Calvinist divine, now turned liberal, and a notable publicist. In 1684 Charles II ordered Locke to be deprived of his studentship at Christ Church, probably as the reputed author of some seditious pamphlets. Locke had, however, an adequate income, not less than £150 per annum, from his paternal inheritance and from an annuity purchased with Shaftesbury's help; he kept a servant and could buy what books he wanted. His English affairs were managed principally by a friend, Edward Clarke of Chipley, Somerset. Money was remitted to him for some time through followers of Shaftesbury who had sought refuge in Holland; but Locke generally avoided them and was not concerned in the preparations for the

duke of Monmouth's rebellion against James II in 1685. In that year, fearing lest the English government should seize him, he lived for a time in concealment. By 1687 he had outgrown his fears and went to live in Rotterdam with an English Quaker, Benjamin Furly.

Until 1686 Locke had published nothing except a few Latin poems contributed to various books. In that year Le Clerc started a periodical for scholars and men of letters, the *Bibliothèque universelle et historique*; he paid great attention to it to English books and ideas. To it Locke contributed (all in French) an account of his method of indexing commonplace books; then abstracts of several new books; then, in Dec. 1687, an abridgment ("abrégé") of his *Essay Concerning Human Understanding*. He sent copies to English friends and sought their criticism. He had already written for Limborch his *Epistola de Tolerantia*, which was published without his name at Gouda in 1689 (for the translation by W. Popple, see below). In it he holds that, in regard to the state, churches are voluntary societies; the state has no right to interfere with them or their members except when they break laws purely secular (e.g., human sacrifice is punishable as murder); where the head of a church is under the control of a foreign government the state may restrict toleration in order to defend itself. Though Locke could not forget England, the *Epistola* was written not so much to influence English policy as to defend Protestantism, which was now threatened not only in England, where James II was using toleration to establish the ascendancy of the Roman Catholic Church, but also in France, where Louis XIV had subjected the Protestants to the dragonnades and then deprived them of all their confessional rights by revoking the Edict of Nantes, and in Holland, where the Calvinist clergy, so far as the government would permit, ruthlessly attacked dissidents, especially Unitarians. In 1692 Limborch published his *Historia Inquisitionis*, in which, even more strongly than Locke, he condemned all religious persecution as unchristian.

By the time that the *Epistola* was published the Revolution of 1688-89 had taken place in England, displacing James II in favour of William III. Locke returned in Feb. 1689 in the ship that carried the princess Mary, William's consort. Though the new settlement did not provide everything that he desired, it brought the crown under parliamentary control and provided in practice a large measure of religious liberty; the constitution could be altered by legal means, without recourse, as so frequently hitherto, to violence. Locke became attached to a new generation of strictly constitutional Whigs, whose leader was Sir John Somers (later Baron Somers). On his arrival William III offered Locke the post of ambassador to Brandenburg; this he refused on account of his health and unsuitability. He was appointed a commissioner of appeals in excise cases, with an annual salary of £200 and easy duties. But he could not tolerate the London winters, and in 1691 took up residence with an old friend, Lady Masham (Damaris, daughter of Ralph Cudworth, the Cambridge Platonist), at Oates in Essex, about 20 mi. from London. He visited London every summer until 1701. He exercised some political influence through Somers and through "the College" a small group of his friends, including Clarke, who was a member of parliament from 1690 to 1710.

In Oct. 1689 there appeared, without Locke's name, *Two Treatises on Government* (all copies dated 1690), the book composed in reply to Filmer, with some passages retouched or added and a dedication to William III. Part of the first treatise had been lost, but James II's conduct had shattered the concept of the divine right of kings. The second treatise was so appropriate to the new situation that until the middle of the 20th century it was always regarded as having been written to vindicate the Revolution. About October also appeared *A Letter Concerning Toleration*, the translation by William Popple of the *Epistola de Tolerantia*. It aroused some controversy, and Locke wrote two further letters, both anonymous, to vindicate his position. The *Essay Concerning Human Understanding* was published in Dec. 1689 (all copies dated 1690). It made its mark at once. Many of Locke's contemporaries felt the need of a new attempt to reach ultimate truth; the book, thanks to its plain language and the care

taken in demonstration, was easy to understand. During the rest of his life Locke had to prepare fresh editions, to superintend a French translation (by P. Coste, 1700) and to answer criticism. An abridgment by John Wynne (1695) came into use at Oxford.

While Locke was in Holland, Clarke had consulted him about the education of his son. Using his replies, Locke put together a book published in 1693, *Some Thoughts Concerning Education*. Intended specifically for the sons of the English country gentry it was widely diffused in England and on the continent of Europe and ranks as a classic of educational theory. Locke's last major book, *The Reasonableness of Christianity*, appeared without his name in 1695. In it he urged the rational element in the Gospels. Although he remained an Anglican, the book appealed to Unitarians and Deists and brought him into fresh controversy.

Meanwhile "the College" was discussing Locke's political views and Clarke was bringing them before the house of commons. Locke was especially concerned with the freeing of the press from the Licensing acts (1695) and with the recoinage of 1696. In 1692 he wrote for Somers *Some Considerations of the Consequences of the Lowering of Interest, and Raising the Value of Money*. Early in 1695, when the bad state of the silver coinage was a principal factor in a great financial crisis, he wrote *Some Observations on the coinage question*. In the summer he and Isaac Newton were consulted by Somers (now lord keeper of the great seal) and the chancellor of the exchequer. William Lowndes, the secretary of the treasury, proposed a scheme for devaluation. Locke in reply published *Further Considerations Concerning Raising the Value of Money*, in which he argued for maintaining the standard. Those of his proposals that were practical were adopted. The question, which was the better scheme, Lowndes's or Locke's, is controversial; on one permanent issue, the coinage as a pledge of public faith, Locke exerted an important and lasting influence.

In 1696 Locke was appointed a member of a new council of trade and plantations, at an annual salary of £1,000; despite his deteriorating health he was an active member until 1700, when he resigned. Besides his controversial pieces he wrote in his last years paraphrases of and notes on some of St. Paul's Epistles, and *The Conduct of the Understanding*, which he planned as a fresh chapter of the *Essay*; these and other pieces were published posthumously. He died at Oates on Oct. 28, 1704, and was buried nearby at High Laver.

In person Locke as a young man was handsome. He was strictly continent and had little wish to marry. He is notable for his many long-lived friendships with men and women, and for his happy relations with children. He had a quick temper that sometimes escaped control; was reticent about his private affairs, and in early life perhaps closefisted. His harshness in proposals for the treatment of the poor is apparent rather than real. He was devout, though incapable of strict orthodoxy in any church. He could not be a scholarly recluse; politics, the life of the great world, concerned him almost as much as intellectual life; he felt himself obliged to make the best use of his talents. Distrusting imagination, or, rather, fancy, and emotion, averse to speculation, he exalted reason as, next to revelation, mankind's guide in life and thought.

Manuscripts and Editions.—The Bodleian and other libraries have many of Locke's private papers, including drafts or final versions of some which he did not publish, early drafts of the *Essay* or of other books published by him, notebooks of various kinds, the greater part of his journals from 1675 to his death, and a huge amount of his correspondence and business papers. The bulk of the material is catalogued by P. Long, *A Summary Catalogue of the Lovelace Collection of the Papers of John Locke in the Bodleian Library* (1959).

The diffusion of Locke's printed writings is remarkable. At least 12 editions of his collected works appeared between 1714 and 1823, followed by one called the 12th, in nine volumes, in 1824; a French translation in 1821-25. Of the *Essay*, there were 28 or more editions in English by 1838; 9 editions of Coste's French translation by 1774; 4 editions of a Latin translation; and abridgments. *Some Thoughts Concerning Education* was translated into French, Italian, German, Swedish and Czech. The

diffusion continued, probably at a slower rate, later in the 19th century and was still continuing in the 20th (notably in Italy after 1945).

Besides A. C. Fraser's edition of the *Essay*, two volumes (1894; facsimile 1959), and a reprint of the 5th edition by J. W. Yolton (in Everyman's Library, two volumes, 1961), there are abridgments by A. S. Pringle-Pattison (1924) and by R. Wilburn (in Everyman's Library, 1947); of the early drafts, the first is edited by R. I. Aaron and J. Gibb (1936) and the second by B. Rand (1931). The *Two Treatises of Government* are edited by P. Laslett (1960); there is another edition in Everyman's Library; and the second treatise is also printed in *Social Contract* (World's Classics, 1947), with an introduction by Sir Ernest Barker. J. W. Adamson's edition of *Locke's Educational Writings* (2nd ed., 1922) contains *Some Thoughts Concerning Education*.

LOCKE'S PHILOSOPHY

Theory of Knowledge.—Locke was thoroughly suspicious of the view that a thinker could work out in his study by pure reason alone the truth about the universe. Much as he admired Descartes, he feared this speculative spirit in him, and he despised it in the scholastic philosophers. In this sense he rejected metaphysics. Knowledge of the world around us could only be gained by experience and reflection on experience, and this knowledge was being gained by Boyle, Sydenham, Christiaan Huygens and Newton. They were the true philosophers who were advancing knowledge. Locke set himself the humbler task, as he conceived it, of understanding how this knowledge was gained. What was "the original, certainty and extent of human knowledge, together with the grounds and degrees of belief, opinion and assent"?

Empiricism.—As for "the original", the answer was plain. Knowledge of the world around us began in sense-perception, and knowledge of ourselves in introspection, or "reflection" in Locke's language. It did not begin in innate knowledge of maxims or general principles, and it did not proceed by syllogistic reasoning from such principles. In the 17th century there had been much vague talk about innate knowledge, and in book i of the *Essay Concerning Human Understanding* Locke examines this talk and shows its worthlessness. The case that he makes against innate ideas, being now of historic interest only, need not detain us. The only question that remains is whether there is innate knowledge in another sense (or in other senses) ignored by Locke, but this too is something that we need not here consider. In book ii of the *Essay* he begins by claiming that the sources of all knowledge are sense-experience and reflection; they are not themselves, however, instances of knowledge in the strict sense, but they provide the mind with the materials of knowledge—and already Locke is opening the door for the phenomenalism and the idealism of the future. Sense-experience is not direct knowledge of the world as it is. The senses provide the mind with "material"; he is not sure what to call the material so provided, perhaps "species" (as the scholastics did) or "notions", but he finally decides on "ideas." These are the objects "before the mind," but we must not assume that the ideas are the physical objects. Rather they represent them; and though we may concur with common sense that, for instance, physical things have size, shape, weight, as they appear to have, yet in respect to colour, taste, smell and so on we may seriously doubt whether things are as they appear to be in sense-experience. In a word, Locke accepts the representative theory of sense-perception and holds that while some of the representations are exact copies of the physical, most of them are not. On this basis he distinguishes between what he calls primary qualities, such as size, weight, etc., and secondary, such as colours, tastes, smells and sounds.

Locke now proceeds to group and classify the ideas, with a view to showing that the origin of all of them lies in sensation and reflection. For though they are immediately "before the mind" not all of them are simple. Many of them are compounded and

their simple parts can be revealed on analysis. It is these simples alone which are given in sensation and reflection. Out of them the mind forms complex ideas, though Locke is ambiguous on this point. For while he uses the language of "forming" or "compounding" and speaks of the "workmanship" of the mind, yet the compounding is frequently in accordance with what is perceived "to go together" and is not arbitrary. A conflict is apparent between Locke's desire to sustain the common-sense view that we do know physical objects and the demands of his compositionalist theory that all ideas can be reduced to the simple ideas of sensation and reflection of which they were originally compounded. Further troubles met him in his attempt to classify ideas. While the idea of a particular apple may be a complex of round, sweet, red, etc., what of the general idea of apple? And what of ideas of relation, such as taller than, identical with, etc.? Locke's compositionism in this part of the *Essay* is patently insecure; yet its purpose is clear, namely, to provide him with a method of showing that all ideas, however remote they may appear to be from sense-experience and reflection, are in fact derived from these sources and from no other. This applies even to the idea of infinity itself. Ideas of space, time and number and mathematical ideas are derived, too, from simple ideas. Locke saves himself from the difficulties inherent in this position by the superficiality of his treatment.

So, too, his reflections upon cause and effect, had they been elaborated, would undoubtedly have led him into acute difficulties. He does admit one failure. As an empiricist he can give no account of the idea of substance; it is, he thinks, essential and not to be denied, and yet it is not a simple idea given in sensation or reflection nor is it derived from simple ideas so given. In fact he can say little of it; it is "a-something-I-know-not-what." Thus the case for empiricism cannot be said to be entirely established by book ii, but Locke thinks it strong enough for him to persist in the view that our knowledge of the physical world is wholly derived from sense-perception.

Self-Knowledge.—Some of our ideas are not of things outside us, but are reflexive and of ourselves. Locke finds it necessary to classify these in book ii and in doing so sets down the foundations of empirical psychology. His source of information is introspection and rarely the observation of behaviour. His account of sense-perception is celebrated for its appreciation of the part which the interpretative mind plays in perceiving, and some of his farsighted observations on the relations between the senses, particularly vision and touch, have profoundly affected subsequent thought. He makes valuable remarks on memory, on discerning, on comparing, on madness, on pleasure and pain, on the emotions and on the association of ideas.

Locke holds that we have an intuitive knowledge of our own existence and supposes that we exist as material and immaterial substances, but he is none too clear about this and at one point plays with the idea that we are simply material substances to which God has "superadded" a power of thinking. His most valuable contribution, however, is his account of personal identity. Having distinguished between different types of identity, he argues that personal identity depends on self-consciousness. I am the person who did so-and-so 20 years ago because I can remember myself doing it. This is the key to the identity of persons.

Language.—Locke tells us that book iii, on language, "cost him more pains" than any other book of the *Essay*; yet it is the book which has been most neglected. To understand our thinking and knowing we must understand the language with which we think and communicate our thoughts. Words are conventional signs; but signs, according to Locke, not immediately of things but of ideas of things, so that he carries his theory of ideas into his account of language. Frequently, the idea signified by the word is not clear and sometimes we use words when we have no ideas corresponding to them. This is particularly so in the case of general words, without which language would be so impoverished as to lose most of its worth. What is involved in the use of general words? The answer, in Locke's mind, is bound up with the theory of universals. Does the general word stand for a particular idea which is used in a representative capacity? Or is the universal

nothing more than a creation of the mind, through abstraction, to which is attached a name? Or, again, is it simply the manner in which we desire that this general word be used? Locke considers these matters without giving a definite answer, but in dealing with natural substances he is inclined strongly toward a conceptualism according to which the use of general words is possible only because in using them we have in mind "nominal essences," that is to say, not the real essences of things but what we mean by these general words. On this view what we mean is the concept, something we have ourselves brought about, the "workmanship of the understanding." Locke also discusses the names of simple ideas and of relations, and it is interesting to find the crude beginnings of a discussion of what were later to be called logical or operative words. Book iii contains also a valuable account of definition, which denies the theory that all definition must be *per genus et differentiam*. The final chapters deal with the inevitable imperfections of language and with avoidable abuses.

Conclusions.—After the consideration of the "materials" of knowledge in book ii and of language in book iii, Locke is ready to discuss the nature and extent of human knowledge. It is noticeable that the tone of book iv is more rationalistic than is that of the previous books, and this is because the skepticism which emanated from his empiricism drove him to find the ideal of knowledge in the indubitable certainties of mathematics. Here he was on common ground with the rationalists of his day, and indeed the direct influence of Descartes seems to be observable in the opening chapters of book iv. Knowledge is perception; not sense-perception but intellectual perception or intuition. We do not, however, gain all the knowledge that we require by direct intuition; we have frequently to proceed discursively, that is, by demonstration. But even when this is so, each step in the demonstration is observed intuitively, so that knowledge in the strict sense is essentially intuitive. "This part of knowledge is irresistible and, like bright sunshine, forces itself immediately to be perceived, as soon as ever the mind turns its view that way; and leaves no room for hesitation, doubt or examination."

Unfortunately, what can be so intuited is limited, as is too what can be demonstrated. We need not confine strict knowledge entirely to mathematics, but the intuition of relations within the physical world is beyond us. Books ii and iii have shown that we deal directly with ideas and nominal essences and that the inner nature of real things cannot be known by us, so that "science," in the exact sense of perfectly certain knowledge, is not possible in this sphere. The only possibility of intuiting, consistent with books ii and iii, is that within the world of ideas, an ideal world, be it noted, which is for Locke empirically derived and not intellectual in character. Knowledge in general terms he accordingly defines as the intuition or "perception of the connection of and agreement, or disagreement and repugnancy, of any of our ideas." If we keep ourselves within ideas—and this is the case in mathematics, for instance—we gain indubitable knowledge, but when we deal with ideas "whose archetypes are without them" we are less sure.

The connections between ideas may be of four kinds: (1) identity or diversity; (2) relation, such as larger than, wider than, etc.; (3) co-existence, such as the co-existence of malleableness and yellowness in my idea of gold; and (4) real existence. Of these four, knowledge of identities and differences is as wide as the ideas themselves; if we have the idea of a spade we know that that idea is itself, and that it is not the idea, for example, of a hammer. This division points somewhat vaguely to a fourfold grouping which is certainly not dominated by the subject-predicate relation.

Secondly, in dealing with the relations between ideas which are their own archetypes, for instance in mathematics, we need seek no further than the intuition or perception itself. But when, thirdly, we affirm co-existences there is an implied reference beyond the idea to the thing itself; and clearly this is also the case when, fourthly, we say that something exists. In these cases, therefore, our certain knowledge is not likely to extend very far. In other words, Locke distinguishes here between logical and factual truth. Certain knowledge, he thinks, is possible of the former, but not of the latter.

In spite of this, and somewhat inconsistently, Locke thinks that we do have knowledge approaching certainty in our "sensitive knowledge" of the existence of physical things. Further, we intuit our own existence. In these cases knowledge which is not an apprehension of a relation between ideas is none the less certain. But he makes it clear that, for the most part, when we talk of knowledge of the physical world and of ourselves, such knowledge is probable and not certain. It rests not on intuition but on judgment; it is assenting to a proposition on the strength of the evidence, and there may be degrees of assent and wrong assent or error. Locke recognizes the need for a logic of probability; though he does little himself in the chapters devoted to probable knowledge at the end of book iv to meet that need. Yet it should be added that the important regular-sequence theory of induction, afterward developed by Berkeley and Hume, is put forward in the pages of Locke's *Essay*. He speaks, too, in book iv, though only briefly, of "habitual knowledge" and is aware of the dispositional element in knowledge.

Political Theory.—Locke's most important work on political philosophy is that entitled *Two Treatises of Government* (1690). The first treatise, as has been explained above, is a refutation of Sir Robert Filmer's defense of the divine right of kings; the second and more important treatise refutes the absolutist theory of government as such, particularly that found in Hobbes' *Leviathan*, though the latter work is not mentioned.

Locke defines political power as "a right of making laws, with penalties of death, and consequently all less penalties for the regulating and preserving of property and of employing the force of the community in the execution of such laws, and in the defence of the commonwealth from foreign injury, and all this only for the public good." He seeks to show the inevitability of this institution in terms of theories of natural law and of social contract which, as held by Locke, are both now discredited. The outcome of his explanation is that only such political power can be justified as is genuinely "for the public good." This means that government is a trust, forfeited by a ruler who fails to secure the public good. The ruler's authority, that is to say, is conditional rather than absolute. Nor does the individual abrogate all his rights when he enters a civil society. He has established his right to property, by "mixing his labour" with things originally given to mankind in common, but now made his own by his labour. (Here in germ is the labour theory of value.) He has the right to expect political power to be used to preserve his property, in his own person and in his possessions. He has the right to think as he chooses, to worship as he wishes, to freedom in speech. In fact the one right which he gives up in entering a civil society is the right to judge and punish his fellow man which is his right in the state of nature. He quits his "executive power of the law of Nature" and "resigns it to the public"; he himself makes himself subject to the civil law and finds his freedom in voluntary obedience. "Freedom of men under government is to have a standing rule to live by . . . a liberty to follow my own will in all things where that rule prescribes not, not to be subject to the inconstant, uncertain, unknown arbitrary will of another man." To secure this freedom, Locke favoured a mixed constitution: the legislative should be an elected body, whereas the executive is usually a single person, the monarch; and he argues for a separation of legislative and executive powers. The people are ultimately sovereign, though it is not always clear in Locke's theory where the immediate sovereignty lies. But the people always have the right to withdraw their support and overthrow the government if it fails to fulfill its trust. In economic theory Locke adopted the principles of the mercantilists.

Moral Philosophy.—One searches in vain for a consistent moral theory in Locke. His view that morality can be a science, as certain as mathematics, is well known. This might imply a rationalism, and there are indeed rationalist trends in his moral philosophy—although sometimes when advocating a science of morals he seems to have in mind simply the possibility of an exact analysis of the terms used in moral discourse and the clarification of moral statements. At other times, he puts forward a hedonist theory: "That we call *good* which is apt to cause or increase pleasure or

diminish pain in us." But not every good is moral good: "Moral good and evil is only the conformity or disagreement of our voluntary actions to some law, whereby good or evil is drawn on us, from the will and power of the law-maker." On this view law rests on God's will, "the true ground of morality," though in saying this Locke does not appear to be consistent with what he says elsewhere of the law of nature.

On the question of free will, discussed in the *Essay*, Locke's position at first is determinist, but in the second edition he tries—not very successfully, it must be admitted—to defend the indeterminist theory by holding that man can always "suspend the execution and satisfaction" of any of his desires.

Theory of Education.—The genesis of the work entitled *Some Thoughts Concerning Education* is described above, and in reading this book it is well to bear in mind that the education proposed is meant for a squire's son in late 17th-century England.

A good education, in Locke's view, attends to both the physical and the mental. The body is not to be coddled, on the contrary it is necessary that it should be hardened in various ways. The good educator insists on exercise, play and plentiful sleep, "the great cordial of nature." Young children should be allowed to give vent to their feelings and should be restrained rarely; "the chief art is to make all that they have to do sport and play too." As for mental training, character comes first before learning; the educator's aim is to instill virtue, wisdom and good breeding into the mind of the young. Parents, too, must interest themselves in their children's upbringing and, as far as possible, have them near; for no educative force is more powerful than the good example of parents. A stock of useful knowledge must be imparted: languages, the pupil's own and another modern language together with Latin (Locke thought the practice in his day of teaching Hebrew, Greek and Arabic generally was misguided); geography, history, some anatomy; mathematics, as the "powers of abstraction develop"; and later a little civil law and an introduction to morals, natural science and philosophy. For recreation, training in the arts, crafts and useful hobbies should be available, but these should not take up too much of a young man's time.

Religion.—Locke's reaction against the "enthusiasm" of the sects in his youth had been sharp, and he disliked religious fanaticism throughout his life. He was a broad, tolerant Anglican anxious to heal the breach in English Protestant ranks. His own views on church government and on the priesthood were close enough to those of the dissenters to have made union possible, for he favoured the liberal views of the Latitudinarians, of the Cambridge Platonists and of the Remonstrants of Holland. This becomes manifest in *The Reasonableness of Christianity*, while his commentaries on the Epistles of St. Paul make him one of the pioneers of modern biblical criticism. Two essentials, and two alone, he thinks, are involved in being a Christian: first, that a man should accept Christ as God's Messiah, secondly, that he should live in accordance with Christ's teaching. His point of view is not far removed from that of the Deists on the one hand and the Unitarians on the other, yet he cannot be grouped with them. Christianity, though reasonable, needs revelation as well as reason, for human reason alone is inadequate: there is an experience of God "through His Spirit" without which all religion is empty. However, any act of persecution in the name of religious truth is wholly unjustified, since our knowledge and understanding are so confined.

LOCKE, MATTHEW (c. 1630–1677), English composer who, of all English composers before Henry Purcell, showed most talent for the theatre, was born in Exeter about 1630. He was a chorister at the cathedral there under Edward Gibbons and later, at the age of 18, he visited the Low Countries. Together with Christopher Gibbons, nephew of his former teacher, he wrote the music for James Shirley's *Masque of Cupid and Death* (1653). He also wrote part of the music for Sir William Davenant's *The Siege of Rhodes* (1656), usually considered to be the first operatic entertainment produced in England, and sang in it himself. In the same year appeared his *Little Consort of Three Parts*, for viols. By 1660 he had been appointed Composer in Ordinary to the King. Locke wrote the music for the "king's sagbutts and cornetts," used when Charles II "progressed" from the Tower of London to Whitehall the day before his coronation; he also wrote several anthems for the Chapel Royal. After his own conversion to Catholicism he was appointed organist to the queen. Much of his later music of importance is concerned with the stage: for Thomas Shadwell's *Psyche* (1673), Davenant's version of *Macbeth* (1663) and Shadwell's of *The Tempest* (1674). He died in London in Aug. 1677.

None of Locke's instrumental music contains the harmonic daring so typical of his vocal style, but the consort music mentioned above and other works for viols remain some of the most masterly instrumental music of the century. In the *Tempest* music Locke uses for the first time in English music such markings in the vernacular as "soft," "louder by degrees," and uses tremolos for string instruments. His treatise, *Melothesia* (1673), contains his "Certain General Rules for playing upon a Continued Bass."

LOCKERBIE, a small burgh of Dumfries, Scot., in the district of Annandale, 12 mi. N.E. of Dumfries by road. Pop. (1961) 2,826. It is near the Roman road and of the Roman camps in the vicinity the best preserved is Burnswark (Birrenswark). Lockerbie is famous for its sheep sales, particularly for the great August lamb fair. The Tower of Lockerbie was once the stronghold of the Johnstones, long the ruling family under whose protection the town grew up. At Dryfe Sands, about 2 mi. W., the Maxwells were almost exterminated by the Johnstones in 1593, hence "Lockerbie Lick" became a proverbial expression, signifying an overwhelming defeat.

LOCKHART, JOHN GIBSON (1794–1854), Scottish biographer, critic and editor, whose biography of Sir Walter Scott has been ranked next to Boswell's *Johnson*, was born in Lanarkshire on July 14, 1794, the son of a Presbyterian minister descended from the landed gentry. Educated at the universities of Glasgow and Oxford, he left the latter in 1813 with a first class in classics, studied for the Scottish bar, and was admitted advocate in Edinburgh in 1816, but his reserve unsuited him for that profession. When *Blackwood's Magazine* was founded in 1817 as a Tory rejoinder to the Whig *Edinburgh Review*, Lockhart became a leading contributor and helped to write the notorious *Chaldee MS.* which, lampooning Scottish celebrities in a parody of Old Testament style, made the first number of the new magazine a *succès de scandale*. Whether Lockhart was wholly, or partly, or at all responsible for the early Blackwood attacks on Keats and the Cockney poets must remain a controversial question in considering a magazine where different writers shared the same pseudonyms, but his sobriquet of "the Scorpion" indicates that his fellow contributors recognized the cutting edge of his wit, which flicks playfully but keenly around the contemporary Scottish scene in *Peter's Letters to His Kinsfolk* (1819). But if Lockhart's aristocratic satire has something of the devilment of Byron's, he again resembles Byron in possessing imagination as well as impudence, and the romantic aspect of his nature was expressed in his verse translations, *Ancient Spanish Ballads* (1823). He attempted fiction too, but although one of his four novels, *Adam Blair* (1822), attracted attention by its "daring" theme of a clergyman's failure to resist sexual temptation, it suffers from gentility of treatment.

As a gentleman, a Tory, an advocate and an author, Lockhart became a friend of Sir Walter Scott, whose elder daughter Sophia he married in 1820, and it was through his father-in-law's good

offices that he was appointed editor of the *Tory Quarterly Review* in 1825. To this he contributed much sound literary criticism, and his judicious praise of Wordsworth, Coleridge, Shelley, and of Byron's *Don Juan* should be recalled alongside his damaging attack on Tennyson's *Poems* of 1833. In 1828 Lockhart produced his biography of Burns, a compilation in which his own comments are remarkable for sympathetic insight and freedom from any tendency to patronize. His *magnum opus*, the *Life of Scott* (1837–38), was attacked on publication for its frankness about Scott's faults, but modern criticism has viewed it as an idealization rather than as a denigration of its subject. That Scott was a hero to Lockhart is indisputable, but if the picture of Sir Walter's years of greatest success is painted in the brightest of colours, the biographer's subtle, incisive wit indicates the foibles of Scott himself alongside the follies of his henchmen, the Ballantynes. Lockhart's wife died in 1837, and his son Walter—Scott's heir—in 1853. Poor health compelled him to resign the editorship of the *Quarterly* in 1853, and he died at Abbotsford on Nov. 25, 1854.

LOCKOUT: see STRIKES AND LOCKOUTS.

LOCKPORT, seat of Niagara county, in western New York, U.S., 25 mi. N.N.E. of Buffalo, and part of the Buffalo standard metropolitan area. The city owes its name to five double locks of the Erie canal (now part of the New York State Barge Canal system), which overcome a difference of 66 ft. between the levels of Lake Erie and the Genesee river. Abundant electric power from Niagara falls serves diversified manufacturing interests, including pulp and paper, flour, wallboard, plastics, textiles, brooms, glass, foundry, brass and bronze products, automobile radiators and parts and sundry machine shop products. Located in the heart of the Niagara frontier fruit belt, the district is noted for its apple, peach and cherry orchards. Quarrying of limestone is also significant. In 1792–93, the Holland Land company bought the present Lockport site, and in 1816 sold most of it to Esek Brown, a local tavern proprietor, and 14 others. In 1822 the settlement was made the county seat and in 1823 it became a temporary headquarters for construction on the Erie canal. Lockport was incorporated as a village in 1829 and as a city in 1865. For comparative population figures see table in NEW YORK: *Population*. (A. G. SE.)

LOCKYER, SIR JOSEPH NORMAN (1836–1920), English astronomer, a pioneer in the application of the spectroscope to the sun and stars, was born at Rugby on May 17, 1836. Educated partly on the continent, he obtained a clerkship in the war office in 1857 and was appointed secretary to the royal commission on science in 1870. He became professor of astronomical physics in the Royal College of Science in 1881 and director of the Solar Physics observatory in South Kensington in 1885; he conducted eight governmental expeditions for observing total solar eclipses between 1870 and 1905.

Lockyer initiated, in 1866, the spectroscopic observations of sunspots; announced, in 1868, that the prominences were upheavals in a layer around the sun, which he named the chromosphere, and applied C. J. Doppler's principle to the sun in 1869. In 1868, Lockyer and P. J. C. Janssen, working independently, discovered a spectroscopic method of observing solar prominences without the aid of an eclipse, and to commemorate this discovery a medal bearing the names of both astronomers was struck by the French government in 1872. With the co-operation of Lady Lockyer, he built an observatory at Sidmouth where he carried out many important photographic and spectroscopic researches. He inaugurated the periodical *Nature* in 1869 and edited it until a few months before his death at Salcombe Regis, Devon, on Aug. 16, 1920. He received a Rumford medal from the Royal society in 1874 and was vice-president of the society in 1892–93. He was created knight commander of the Bath in 1897.

In addition to his many scientific papers, Lockyer wrote *Stonehenge and Other British Stone Monuments Astronomically Considered* (1906) and *Inorganic Evolution* (1900).

See T. M. and W. L. Lockyer, *Life and Work of Sir Norman Lockyer* (1928). (O. J. E.)

LOCMARIAQUER, a village of Brittany, western France, in the *département* of Morbihan, lies on the west shore of the Gulf of Morbihan, 14 km. (9 mi.) S. of Auray by road. Pop. (1962) 513. Locmariaquer has a small harbour; it is a seaside resort and oyster culture is carried on. It is famous for its megalithic monuments: standing stones (a huge, broken standing stone, the Fairies' stone, was 66 ft. high) and stone tables (the Merchants' Table, carved slabs). There are some Gallo-Roman remains and a church which dates in part from the 12th century. (Y. Ro.)

LOCOMOTION, ANIMAL. Disregarding some of the lower forms of life, one of the most obvious distinctions between animals and plants is that the former exhibit in striking degree a capacity for locomotion. They move about in pursuit of food, foothold and mates, or in flight from enemies and harmful influences. Locomotion may be defined as the ability of animals to move from place to place by their own actions. It does not include transport by forces such as wind or water currents that carry the animal along, although this is an important supplement to locomotion in some species. The galloping horse clearly is using powers of locomotion; the egg of a fish carried by ocean currents is not. The young spider that climbs to a high branch, spins a long silken thread, then is carried on this thread by the wind, or the Portuguese man-of-war, in which a gas-filled float acts as a sail before the ocean breezes, are passive travelers. Different kinds of animals live successfully through adaptations that vary from highly specialized and efficient methods of locomotion, through a bewildering array of intermediate adaptations, to a completely sedentary, even sessile, mode of life. Thus, while active locomotion is emphasized in this survey article, it is important to remember that in the animal kingdom many alternatives exist. Information regarding the speeds attributed to different animals may be found in many separate articles.

Each animal's powers of locomotion fit, along with its many other faculties, into a complex design that enables it to exist as an individual and as part of a population. The rabbit must run to escape enemies, and is well adapted to do so, while the porcupine is protected by a coat of sharp quills but is not specialized for rapid locomotion. Many birds adapted to particular climatic conditions migrate with the changing seasons. Grazing animals and nomadic human tribes move to new areas when old food supplies become depleted. Fishes move to different depths during different seasons because of changes in the oxygen content and temperature of the water. Many reptiles crawl back and forth from sun to shade during the day, following the environmental temperature that best suits them. Flying insects, because of their great mobility, can exploit widely scattered food supplies. Salmon, which are bound to fresh-water streams by rigid spawning requirements, take advantage of the great abundance of food in the oceans by migrating great distances to the sea. When animals become very abundant locally, they tend to interfere with one another in such vital functions as feeding, respiration or breeding. Dispersal, usually involving locomotion, may then act as a safety valve by reducing the local density of the population.

Adaptations for locomotion reflect both the environmental pressures under which an animal evolved and the basic ancestral body plan from which it was derived. The basic body plan may limit the amount of adaptive modification possible. For example, the vertebrates, having evolved from fishes, are committed to a basic pattern of two pairs of limbs. Some use both pairs for the same type of locomotion (four-footed land mammals); some use each pair for a different type of locomotion (birds); some rely principally upon only one pair (man); and some have vestigial limbs not used in locomotion (snakes). These modifications involved relatively simple evolutionary changes compared with the drastic revision of the vertebrate body plan that would have been required to produce a method of locomotion involving, for example, three pairs of limbs.

BASIC MECHANISMS

Animal locomotion is based upon the ability of protoplasm to convert chemical energy, obtained from food, into the mechanical

energy of contraction. In the amoeba, changes in shape of the entire protoplasmic mass are involved. In other simple animals only specific protoplasmic structures are moved. In most animals, however, locomotor contractions are produced by long, slender muscle cells that contain tiny elastic fibres (myofibrils) capable of shortening and then returning to their original length.

Musculature.—A primitive musculature used in locomotion is found in coelenterates, where the body walls contain opposed sets of epitheliomuscular cells capable of shortening the body or of decreasing its diameter. The flatworms have muscle fibres arranged in longitudinal, transverse and dorsoventral directions; when the muscles contract in one direction, the plastic, fluid-filled body extends in the other two. In roundworms the muscle cells all lie parallel to the main body axis; these animals can bend and straighten by alternately contracting fibres along opposite sides of the body, but they are not able to extend the body lengthwise. Earthworms have an outer layer of circular muscles and an inner layer of longitudinal muscles in the body wall; when the circular muscles contract, the fluid-filled body increases in length, and when the longitudinal muscles contract, the worm becomes shorter.

The arthropods are the only invertebrates that depart from a layered arrangement of muscles. They possess many muscles of different sizes and arrangements, fastened to the internal surfaces of the hard exoskeleton in opposed pairs. These muscles move the body segments and the jointed appendages. The muscles of vertebrates also vary greatly in size and arrangement and, as in the invertebrates, are usually grouped in opposing pairs. They are attached to the exterior of the bones and are used to move the various skeletal components, which function as levers.

The principal component of the muscular system in many invertebrates is smooth muscle, which is capable of only relatively slow contraction. In the arthropods and in the vertebrates striated muscle predominates in structures used for locomotion. This type of muscle is capable of rapid contraction, a decided advantage where speed of movement is important.

Activation.—In the lower animals the protoplasm or contractile fibres respond directly to environmental stimuli such as contact with obstructions or with chemical substances. In intermediate forms the stimulus may be received by specialized sensory nerve endings (photosensitive "eyespot," chemoreceptors, etc.) and the muscle stimulated by an electrical impulse conveyed by a motor nerve process. In vertebrates the complex muscular movements involved in locomotion are basically compound reflex actions, subject to central control through association nerve cells (neurons) connected with parts of the nerve cord and the brain. These reflex actions may be initiated by impulses entering on one sensory neuron and affecting several motor neurons; by impulses from several sensory neurons compounded to act on a single motor neuron; or by chain reactions in which the response of one reflex becomes the stimulus for the next. Many related reflexes are co-ordinated by the nervous system in producing the complex muscular movements of walking or flying.

INVERTEBRATES

Advances From Protozoa to Arthropoda.—A major group of protozoans, the Mastigophora or Flagellata, possess long, filamentous, protoplasmic extensions called flagella, which beat in whiplike fashion, drawing the animals through the water. Unicellular forms such as *Euglena* revolve on their long axis as they swim forward. *Euglena* can also crawl wormlike by altering body shape through local expansions and contractions. This method of locomotion, called euglenoid movement, is controlled by protoplasmic contractile fibres. Colonial flagellates such as *Volvox* consist of many individual cells imbedded on the surface of a gelatinous ball. The flagella beat in co-ordinated waves causing the ball to roll over and over as it moves through the water, but one end of the colony always remains oriented forward.

In a second group of protozoans, the Sarcodina, each animal literally flows along over the substrate in what is called amoeboid movement. The protoplasm at the trailing edge of the organism changes in consistency to a thin "plasmasol" state and flows forward, thickening to the "plasmagel" state at the leading end. The

plasmagel then passes backward, increasing in elastic strength as it goes. During the continually reversing gel-sol process, the amoeba may be temporarily and reversibly attached to the substrate, possibly by a secretion. This method of locomotion is found in modified form in some more advanced animals. Individual cells isolated from sponges are capable of amoeboid movement. The coelenterate *Hydra* can glide along by the pseudopodial-like action of the cells on its basal disc. In the higher vertebrates, most of the white blood cells are capable of amoeboid movement within the animals' tissues.

In a third class of protozoans, the Ciliata, the organisms possess fine, hairlike projections called cilia on the surface of the protoplasm. *Paramecium* is a typical example. The cilia beat backward to carry *Paramecium* through the water. Because the animal is not quite symmetrical and the ciliary stroke is oblique, *Paramecium* rotates on its longitudinal axis as it moves, following a spiral course about a straight line. When the animal meets an obstacle in its path it backs up by reversing the beat of the cilia.

Locomotion by the action of cilia is also found in some higher invertebrate phyla. The sponges, which are incapable of movement through most of their lives, have a ciliated, free-swimming larval stage. Ciliated larvae also occur in the coelenterates (the planula of colonial hydroids) and in the bryozoans and the marine annelids (trochophore). In free-swimming rotifers, an anterior crown of whirling cilia is the chief means of locomotion. Free-living flatworms glide along a slime track, laid down by epidermal glands in the head end of the animal, by means of backward strokes of cilia on the ventral surface.

Flatworms can also crawl by contracting the circular and dorsoventral muscles to elongate the body, anchoring the head end by a sticky mucus, then drawing the body forward by contraction of longitudinal muscles. Many nematodes are covered with minute bristles, spines or scales that assist them in crawling through the soil. Mollusks glide smoothly along a slime track secreted by a gland below the mouth, propelled by waves of muscular contraction on the underside of the protruding, fleshy foot. Clams and oysters extend the foot between the valves of the shell, hook it to the substrate or wedge it into a crevice and fasten it by expansion, then contract the foot to drag the shell forward. The earthworm crawls through the soil by forcing its slender anterior end into crevices, then swelling the pharynx to force the soil particles outward; or by actually eating its way through the ground. The bristlelike setae are used to grip the sides of the burrow, and alternate lengthening and contracting of the body carries the animal forward. The starfishes and other echinoderms crawl along the bottom in marine habitats by extending their arms, gripping the substrate with suction cuplike tube feet, then contracting so as to pull the animal along; sea urchins, which do not have tube feet, use movable spines or bristles on the under-surface for locomotion. A different mode of crawling is found in *Hydra*, which can loop along like a measuring worm, attaching the tentacles to the substrate by nematocysts, releasing the basal disc from its original location on the substrate and attaching it at a new location, then releasing its grip with the tentacles. Leeches and some rotifers are capable of a similar type of locomotion.

Not all these invertebrates are limited to some form of crawling or the protozoan modes of swimming for locomotion. Marine clam worms swim in much the same manner as snakes, by lateral wiggling of the body. Jellyfish can swim feebly by contracting the bell rhythmically, forcing water out of the cavity. Squids and octopuses eject water from their mantle cavities to provide underwater jet propulsion; they can turn the siphon through which the water is expelled to control their direction of movement. Some animals in this group also swim by means of fins. A few rotifers use the taillike posterior end of the body as an organ for catapulting. And terrestrial planarians of the tropics lower themselves from leaf to leaf on self-produced threads of slime.

Arthropodan Innovations.—Possession of jointed appendages and a diversified musculature opens up many new opportunities in locomotion. The basic arthropod body plan of many segments, each with a pair of appendages, lends itself readily to

a wide variety of adaptations through fusion or modification of some segments and specialization of appendages. Thus, various arthropods have become accomplished swimmers, runners, jumpers, burrowers or fliers.

In crustaceans such as the fairy shrimps and water fleas the same feathery appendages function as both breathing and swimming organs. In copepods, antennae attached to the head are used in locomotion, along with thoracic legs. The amphipods have climbing legs on the thorax and swimming and jumping legs on the abdomen. The sowbug *Asellus*, which spreads its weight over a large area of the substrate by walking on seven pairs of feet, can travel easily over thin, unstable bottom muds. Crayfish, lobsters and crabs have eight thoracic segments that bear the true limbs; these are variously modified, with the last four usually functioning as walking or swimming legs. Arachnids have four pairs of legs; most are active runners and climbers in terrestrial habitats. Millipedes, commonly called "thousand-legged worms," have from 20 to 100 segments to the trunk, each of which bears two pairs of legs. The legs move in a series of waves, carrying the animal smoothly along.

Practically all insects are capable of walking or crawling. In the adults three pairs of legs, variously specialized, provide efficient locomotion in many different environments. Insects may crawl beneath the surface of the water, atop the surface film, on dry land, over vegetation and even on glass-smooth surfaces. Some seemingly defy the law of gravity by maintaining a footing while climbing sheer vertical walls or walking upside down across ceilings. Various types of claws provide a firm grip on irregular substrates. Pulvilli (hairy pads or suckerlike structures on the feet) enable some insects to adhere to very smooth surfaces. In the praying mantis the first pair of legs is specialized for grasping food and only the remaining two pairs are used for locomotion. Grasshoppers can jump with great agility, powered by the enlarged third pair of legs, the first two serving for slow walking and clinging. Insect larvae may be without legs, have the usual three pairs or have additional prolegs such as are found in caterpillars. In some of the legless forms, locomotion is by means of pseudopods. Insects that inhabit fast-flowing streams have greatly flattened bodies and legs, adaptations that allow them to cling closely and to crawl on the surfaces of submerged rocks without offering much resistance to the swift currents. The water strider *Gerris* has a velvety, nonwettable hair pile and long legs with which it scampers across the surface film of lakes and streams, the specialized structure of the feet preventing the insect from breaking through. The second and third pairs of legs in water scorpions are long and slender, enabling them to run among tangled mats of vegetation. The back swimmers (Notonectidae) have long, oarlike back legs, fringed with long hairs; these insects row themselves through the water on their backs. Many other aquatic insects have flattened, fanlike hairy legs that are used as oars. Dragonfly nymphs use jet propulsion as an auxiliary means of locomotion, by using sudden muscular contractions to force water through a terminal opening in the abdomen.

Among the invertebrates only the insects are capable of flight. The same aerodynamic principles that underlie the flight of birds and of airplanes appear to be adequate to explain insect flight. However, at present no mathematical theory of the way in which lift and thrust are generated by wing motion has been developed. During flight the wing action, angle of attack, wing tip path and velocity, acceleration and twisting of the wing, stroke amplitude, stroke-plane angle, frequency of beat, etc., all can be varied. Thus insect flight is clearly an enormously complicated subject.

In some insects muscles power the wings directly. In others the muscles control movements of the exoskeleton, which in turn moves the wings by exerting leverage. In general the smaller the insect the more rapid the wing beat must be to provide sufficient lift for flight. In insects with very rapid wing beat the muscular contractions that power each beat are not each triggered by a motor nerve impulse; motor nerve impulses bring the muscle fibres to a state of excitation in which they are stimulated by stretching to contract. Two antagonistic sets of muscles alternately relax and contract much more rapidly (sometimes in excess of 200 times per

second) than motor nerve impulses can be generated continuously. See FLIGHT (NATURAL).

VERTEBRATES

In the vertebrates the principal means of locomotion is through variously adapted propulsive levers, consisting of parts of the skeleton such as limbs or vertebrae, powered by muscles which are arranged in opposing pairs. One muscle of a pair pulls the lever forward; the other muscle pulls the lever backward again.

Swimming.—The simplest arrangement is found in aquatic animals, where the vertebrae act as the lever. Thus, the head of a fish may be thought of as a fulcrum for the flexible tail-end lever. The entire propulsive force derives from the muscles of the trunk. Swimming is accomplished by sweeping the tail from side to side, in much the same manner that a boat may be sculled with a single oar. Aquatic mammals, such as whales and dolphins, swim in the same way as fishes except that the posterior part of the body is flattened horizontally instead of vertically, and locomotive force is generated by sweeping the tail up and down rather than from side to side.

The streamline body form of most fishes and the mucus covering that reduces friction help them to move swiftly through the water. The viscosity of water is about one hundred times as great as that of air, so the problems posed by frictional resistance to a moving body are much greater for a fish in the water than for a man who moves through the fluid medium of air. The speed of a fish is roughly proportional to the frequency of the tail beat and the length of the body. The maximum speed a small fish can attain is about ten times its length per second. Fish regulate their depth in water by action of their air bladders, which can be inflated or deflated, and adjust their direction and balance by using their fins.

The body shape of fishes is roughly related to their swimming habits. Departures from streamline form occur at the expense of swimming speed. The most streamlined fishes are usually those that swim the open waters or that are predaceous. Alternatives to locomotion by means of body sculling are found in the tropical parrot fish, which rows itself along with the pectoral fins; the trunk fish, which sculls its inflexible body with its free caudal fin; and the seahorse, which propels itself with its dorsal fin. Other fishes may creep along the bottom with the aid of the pectoral fins, burrow in the bottom or move short distances propelled by jets of water from the gill chambers. The flying fish leaps into the air and glides by means of greatly enlarged pectoral fins, after attaining considerable speed swimming just beneath the surface.

Crawling.—In the sense of locomotion in which the body is in direct contact with the substrate, crawling is perhaps most typical of the snakes. The principal locomotive movement of snakes is termed "horizontal undulation." It resembles the swimming motion of fish in that the body is curved, the curved section being forced against a relatively stable medium with which the animal is in contact. Rather than a single body curvature as in fish, however, snakes throw their body into a series of gentle horizontal curves, and the body is pressed against the ground or vegetation at each curve. The entire body moves forward at the same time, each part following smoothly along the path traced by the part immediately ahead. This mode of locomotion is made possible by the great number of vertebrae (sometimes more than 200) which constitute the backbone. Some heavy-bodied snakes, such as rattlesnakes, can crawl in a straight line by alternately pulling the skin forward on the body, anchoring the edges of the belly plates against the substrate, then inching the body forward within the skin. The sidewinders, especially adapted for moving across loose desert sand, throw the anterior part of the body through the air followed by the rest of the body, which comes forward and sideways in a rolling motion. The body is not dragged but rather "looped" at right angles to its long axis. All snakes can swim by using the same horizontal undulation as in terrestrial movement. Snakes are also excellent climbers; because of their length they are able to distribute their weight evenly over tree branches or other upright objects. Some climb vertically by pressing the belly plates into irregularities in the surface up which they are moving. Others

are especially adapted to life in trees, their long slender bodies enabling them to reach from one branch to another. Snakelike locomotion is also found in other vertebrate groups, such as very elongated fishes and lizards, where certain lines of specialization have resulted in great reduction or loss of the limbs.

Flight.—Among the vertebrates the birds are the undisputed masters of flight. The same principles that underlie flight in airplanes are utilized in bird flight. When moved through the air, the streamline wing provides lift because of greater air pressure on the lower surface than on the upper. An auxiliary airfoil, the equivalent of a small wing in front of the main wing, can increase the speed of airflow over the main wing and thus maintain lift at slow air speeds. The alula, or bastard wing, a group of feathers at the forward edge of the wrist, performs the function of an auxiliary airfoil in birds. The inner wing, from the shoulder to the wrist, provides lift and is analogous to the wing of an airplane. The outer wing, from the wrist to the tip, acts as a propeller and generates forward thrust in flight. The outer half of the bird's wing is moved from the wrist joint, while the inner half is moved from the shoulder joint. The primary feathers near the wing tips twist as the wings beat, taking the proper shape and angle to function as propellers. The path of these feather propellers is down and forward on the downstroke of the wing and up and backward on the upstroke of the wing.

In addition to flapping flight some birds (albatross, vulture, gull) are specialized, by means of long narrow wings, for gliding. They exploit vertical warm air currents rising from the surface of land or water to bear them aloft with little expenditure of energy.

The only mammal capable of true flight is the bat; others such as flying squirrels do not fly but are able to glide for relatively short distances, using folds of skin that are stretched between the forelegs and hind legs as "wings."

Walking and Running.—In animals such as salamanders body undulations much like those of a fish are of primary importance in locomotion, but the limbs also play a prominent role. Dogs and cats, which arch the back during running, greatly increase the speed and power of the hind limbs by contracting the muscles in the back. Possibly the ultimate development in terrestrial locomotion is that of the horse, in which nearly all the power is provided by the muscles of the limbs. For combined speed and endurance in running, animals such as the horse are the champions of the animal world. Large cats such as the cheetah are capable of spurts of speed but tire quickly.

An animal's centre of gravity may be near the forefeet, as in the horse, near the hind feet, as in rabbits and bears, directly above the hind feet, as in birds and man, or behind the hind feet, as in the kangaroo (which, as a consequence of its weight distribution, must balance partly on its tail when at rest). These differences in location of the centre of gravity are related in important and usually obvious ways to locomotion.

Four-legged animals walk by lifting one foot at a time, swinging it forward, and placing it on the ground some distance ahead. When the extended foot touches the ground it begins to act as a fixed fulcrum from which the action of the muscles on the limb lifts the body forward. The normal order of movement of the feet in unhurried walking is: right fore, left hind, left fore, right hind. At a fast walk a point is reached where each foot is lifted off the ground before the one ahead has been returned, and the animal balances for brief periods on only two feet. As the speed of movement is increased, a stage is reached where there are never more than two feet in contact with the ground. In this two-point gait the legs never provide an adequate triangle of support for the animal's body, and balance is maintained only by bringing each new pair of supporting legs into use quickly enough to correct the imbalance. When the two-point gait becomes fast enough that a limb is in contact with the ground for a shorter time than it is off, there are intervals when the animal is not in contact with the ground at all. Finally, at a gallop, only one foot at a time is in contact with the ground; between the periods of contact none of the feet touch the ground. The order in which the limbs are moved in this gait is: left fore, right fore, left hind, right hind—or right may precede left.

Other Modifications.—The jumping vertebrates, such as frogs and rabbits, have relatively long, slender legs that can be folded tightly under the body, then extended full length to push the animal up and forward. This departure from the typical four-legged gaits reaches an extreme in animals such as the kangaroo, which moves about almost entirely on the hind legs. Another line of divergence from four-footed locomotion is found in the apes, some of which swing (brachiate) from limb to limb in tropical forests by means of their arms (modified forelegs), the terminal parts of which are modified for grasping.

The feet of many animals are specially adapted for travel over a certain type of substrate. On hard, rocky ground, feet with nonskidding adaptations, such as those of mountain goats and sheep, are advantages. Animals such as the moose, which inhabit marshy areas, usually have large feet. The webbed feet of ducks assist them in walking on muddy areas as well as in swimming. Many lizards have lateral rows of scales or fringes on the toes that enable them to walk on loose sand. Feathered feet in the grouse and widened feet in the snowshoe hare act as snowshoes. Suckers on the feet of tree frogs and claws on various mammals are aids in climbing.

LOCOWEED, certain North American species of the genera *Astragalus* and *Oxytropis* of the Leguminosae (pea family), found mainly in arid and semiarid regions of the western and southwestern United States, which when ingested cause a cattle disease called loco ("mad"). Animals so poisoned stagger and become stuporous. The toxic properties may result from selenium absorption by the plant (some *Astragalus* species), or an unknown intrinsic alkaloid (in certain *Oxytropis* species). Some *Astragalus* species also produce a poison which does not induce true locoism. Wholesale eradication appears to be impossible, but individual plants may be killed chemically.

LOCRI, a people of ancient Greece, inhabiting two separate districts, one extending from the northeast of Mt. Parnassus to the northern half of the Euboean channel, between Boeotia and Malis, the other southwest of Parnassus, on the north shore of the Corinthian gulf, between Phocis and Aetolia. The former branch was divided into the Locri Epicnemidii, situated on the spurs of Mt. Cnemis (Knimis), and the Locri Opuntii, so named from their chief town Opus (*q.v.*). Homer mentions only these eastern Locrians; their national hero in the Trojan War is Ajax, son of Oileus, who often appears afterward on Locrian coins. The Opuntians were thought by some ancient writers to be of "Lelegian" origin (*see* LELEGES), but they were hellenized early (though matriarchal customs survived among them). The western Locri Ozolae on the Corinthian gulf were described in the 5th century B.C. as backward and warlike; their chief towns were Naupactus (Navpaktos) and Amphissa (Amfissa). Relations between the two branches were usually close, though they took opposite sides in the Peloponnesian War. For the Locri Epizephyrii of southwestern Italy *see* LOCRI below.

LOCRI, an ancient city on the eastern side of the "toe" of Italy, founded c. 680 B.C., its name derived from that of some of its settlers. The colonists occupied the Zephyrian promontory (Capo Bruzzano), and though after three or four years they moved 12 mi. to the north near the coast, 2 mi. S. of Gerace Marina (now renamed Locri), they still retained the name of Locri Epizephyrii to distinguish them from the Locri (*see* above) of Greece itself. This was the first Greek community to have a written code of laws, given by Zaleucus c. 660 B.C. From Locri were founded the colonies of Medma (Rosarno) and Hipponium (Vibo Valentia). In the 6th century it repelled the attacks of Crotona and later found support in Syracuse against Rhegium. During the Peloponnesian War it was an active adversary of Athenian intervention in the west. Pindar extols it in his 10th and 11th *Olympian Odes*; Stesichorus (*q.v.*) was of Locrian origin. Dionysius I of Syracuse married a Locrian; its territory was then increased and the circuit

of its walls was doubled, but it lost its freedom. From 352 to 346 B.C. it was ruled by Dionysius II. From the battle of Heraclea (280) until 205, when it was captured by Scipio Africanus and placed under the control of his legate, Q. Pleminius, Locri was continually changing allegiance between Rome and its enemies. In later Roman times it was of no great importance. It was destroyed by the Saracens in 915.

Excavations in 1889–90, extended in 1954 *et seq.*, disclosed a sanctuary at the northeast angle of the town—originally, in the archaic period, a Doric temple. This was destroyed about 450 B.C. and a new temple in the Ionic order (rare in the Greek west) built on the ruins. In front are altars for sacrifice. The marble figures from the pediment of the Dioscuri Castor and Pollux (*q.v.*), who according to the legend assisted Locri against Crotona, are in the National museum, Naples. A Doric temple was also cleared under the house called Casa Marafioti: the fine equestrian group in terra cotta from the western gable is, with other objects from Locri, in the museum at Reggio di Calabria. There was also a sanctuary of Persephone from which came numerous terra-cotta votive plaques (*pinakes*) of the 5th century B.C.

The city walls, the length of which was nearly 5 mi., consisted of three parts: the fortified castles with large towers on three different hills, the city proper, and the lower town, the latter enclosed by long walls running down to the sea. Prehistoric objects confirm the accounts of Thucydides and Polybius that the Greek settlers were preceded by Siculi.

See W. Oldfather in Pauly-Wissowa, *Real-Encyclopädie der klassischen Altertumswissenschaft*, xiii, 1289–1363 (1927); T. J. Dunbabin, *The Western Greeks*; esp. pp. 68ff., 293ff. (1948).

LOCUS (meaning "place" in Latin) specifies in mathematics a geometric system which satisfies a given set of conditions. In a plane, for example, the locus of a point at a given distance from a fixed point is a circle whose centre is the fixed point, and whose radius is the given distance. In three dimensions, the corresponding locus is the surface of a sphere. Thus, in analytic geometry the locus of the equation $x^2 + y^2 = 1$ is a circle; while the locus of $x^2 + y^2 + z^2 = 1$ is the surface of a sphere. For diagrams and equations of a number of loci which have attracted the interest of mathematicians see *CURVES, SPECIAL*; *CONIC SECTION*.

LOCUST, any of certain insects of the family Acrididae, which at times multiply greatly and migrate long distances in destructive swarms. In Europe the term "locust" connotes large size; smaller acridids are called grasshoppers (*q.v.*). In North America "locust" and "grasshopper" are used for any acridid. Unfortunately cicadas (order Hemiptera) are also called locusts or harvest locusts; the 17-year locust is the periodic cicada (see *CICADA*).

The Phases of Locusts.—In 1921 B. P. Uvarov satisfactorily explained for the first time the sporadic coming of locust swarms and the apparent disappearance of the insects between times by the phase theory, later substantiated and elaborated by many workers. Each plague species exists in two phases, solitary and gregarious, connected by transitional forms. The extreme phases differ in coloration, form, physiology and behaviour.

Solitary phase nymphs vary in colour and pattern, adjust their colour to match that of their surroundings, do not congregate, have low metabolic and oxygen-intake rates and are sluggish. Gregarious phase nymphs have a black and yellow (orange) coloration of fixed pattern, are gregarious, have high metabolic and oxygen-intake rates and are active and nervous; their dark pigments absorb more radiation. Adults differ less in colour, but often notably in form. The solitary phase has shorter wings, longer legs, narrower pronotum with higher crest and larger head; the gregarious

ous phase has a more saddle-shaped pronotum with broader shoulders and long, ample wings.

Progeny of the solitary phase, reared in crowds, change toward the gregarious type; and if the crowding is of sufficient degree and duration, the extreme of the gregarious migratory phase is produced. Progeny of the gregarious phase, reared in isolation, revert to the solitary phase. By rearing single nymphs in constantly agitated cages J. C. Faure (1932) showed that the effects of crowding result from the unceasing activity it induces. The solitary phase is the normal state of the species, while the gregarious phase is a physiological response to violent fluctuations in the environment. Within the territory of each species its solitary phase exists at all times and in a wide variety of ecological conditions. Swarms do not form in the regions most favourable to the species, but in marginal areas where suitable habitats are restricted and climatic balance is delicate. There a succession of favourable seasons enables the restricted populations to expand into adjoining areas, but return of unfavourable conditions forces the enlarged populations back into the small permanently habitable area and crowding results. The exact circumstances vary with the species and region.

The outbreak areas of the migratory locust of the old world, *Locusta migratoria*, are of four ecological types: (1) deltas of rivers entering the Caspian and Aral seas and Lake Balkhash (and similar situations in China and Africa), surrounded by arid sandy tracts; there the extent of the grassland habitat of the locust changes greatly as a result of irregularities of floods; (2) grassland areas adjoining deserts, subject to extreme fluctuations in precipitation with corresponding changes in extent of habitable area; (3) islands of dry warm soil in the central U.S.S.R., a region generally too cold and wet for the species; there overcrowding occurs after several exceptionally warm dry years; (4) grasslands produced by periodic burning in the unfavourable, humid forestlands of the Philippines; their extent varies greatly, leading to overcrowding and production of the gregarious phase.

Locusts of the gregarious phase are restless and irritable; the bands of nymphs wander, and adult swarms take flight spontaneously.

CAROLINA GRASSHOPPER OR LOCUST
(DISSOSTEIRA CAROLINA)

ously on warm dry days when their body temperature is high. The muscular activity of flight further raises their temperature, and a swarm can therefore cease flying only when conditions change. Rain, a drop in temperature or nightfall will usually stop a flight. The distances traveled may be great; swarms have been seen 1,200 mi. at sea and the desert locust (*Schistocerca gregaria*) reached England in 1869, probably from west Africa. The flights often end in destruction of the swarm. Some swarms are very large; a particularly large flight of the desert locust across the Red sea in 1889 was estimated as 2,000 sq.mi. in extent. The gregarious instinct is strong, and swarms remain compact even when reduced to small size by high mortality; they are dispersed, with resultant transformation into the solitary phase, only by storms and other external factors as mentioned above.

Important Species.—The migratory locust (*Locusta migratoria*, with its races *rossica*, *migratoria*, *migratorioides*, *capito* and *manilensis*) has a wider range than any other acridid. It is found in grasslands throughout Africa, most of Eurasia south of the taiga forest, the East Indies, tropical Australia, and New Zealand. *Schistocerca gregaria* inhabits dry grasslands and deserts from Africa to the Punjab. Its swarms arrive during the summer monsoons in India; in autumn they migrate to Iran and Arabia with others from Africa, and thence spread to soviet Asia, Syria, Palestine and Egypt. In late fall some return to India and East Africa, where breeding occurs during the next monsoon rains. The smaller Italian and Moroccan locusts (*Calliptamus italicus* and *Dociostaurus maroccanus*) do much injury in the Mediterranean area; the second is found discontinuously east to Turkestan. In South Africa the brown and red locusts (*Locustana pardalina* and *Nomadacris septemfasciata*) are both very destructive. In Central and South America the chief migratory species is the South American locust (*Schistocerca paranensis*), of which the nonmigratory *S. americana* of the United States may possibly be the solitary phase. The Rocky mountain locust or lesser migratory grasshopper (*Melanoplus spretus*) wreaked havoc on the prairie farms of Canada and the United States in the 1870s, but later disappeared. The clear-winged grasshopper (*Camnula pellucida*) is a major crop pest in North America. Many other species of Acrididae in different regions occasionally increase to plague proportions but few of them compare in economic importance with those named above.

Control Measures.—Once well started, a locust plague is almost impossible to check, and only palliative measures can be taken. These have included (1) the destruction of egg masses laid by invading swarms, (2) the digging of trenches to trap the nymphs, (3) the use of hopperdozers (wheeled screens, upon

striking which locusts fall into troughs containing water and kerosene) and poison baits and (4) dusting and spraying of swarms and breeding grounds with insecticides from aircraft.

DDT proves virtually ineffective against locusts. One of the most economical insecticides is dinitro-ortho-cresol (DNC); the disadvantages of DNC are that it is also highly toxic to man, since it is absorbed through the skin, and that it kills certain kinds of plants. Dieldrin and more recent organic insecticides are also used. Application from aircraft has proved helpful in subduing incipient swarms, but concerted efforts by ground forces are still necessary to control the nymphs and nonmigrating adults.

The control problem is made difficult by the great extent of the territory affected, with many invasions beginning in sparsely populated, undeveloped regions. Permanent control requires both national and international action. Such control is possible because locust swarms do not arise simultaneously over wide regions but emerge in a few outbreak areas, many of which are known.

In 1932 the Anti-Locust Research centre was set up in London; it directed international surveys and field studies and, during World War II, large-scale campaigns in Africa and Asia against the desert locust. Since that time several other international bodies have arisen to control the locust in Africa. Warnings are given of incipient outbreaks and swarm movements, and control measures are planned and supervised. Ultimately many outbreak areas may be made ecologically unsuitable for production of the gregarious phase, when the ecology and behaviour of each plague species are better known.

LOCUST, the common name given to any tree of the genus *Robinia*, which comprises about 20 species native to North America, belonging to the family Leguminosae, and, as "honey locust," to leguminous trees of the genus *Gleditsia* (see **HONEY LOCUST**). The best known is the black locust (*R. pseudoacacia*), introduced into Europe in 1636. This tree, often called false acacia and yellow locust (acacia in England), is widely cultivated as an ornamental tree. It grows to 80 ft. high, and bears long, graceful compound leaves with 6 to 20 bright green oblong leaflets, and white fragrant flowers in loose pendulous racemes. There are many varieties, varying in the manner of growth, the presence or absence of thorns on the branches and the colour of the flower.

may have a trunk three or four feet in diameter. It has been widely planted to control erosion in fields and gullies. It is a useful timber tree; the wood, being heavy, hard, strong, close-grained and durable, is used mainly for fence posts.

The clammy locust (*R. viscosa*), a tree sometimes 40 ft. high, with pinkish flowers, and the rose acacia or bristly locust (*R. hispida*), a small shrub, with showy rose-coloured flowers and twigs covered with bristly hairs, both native to the southeastern United States, are also cultivated for ornament.

The shipmast locust, a variety of black locust, is used extensively in reforestation projects, and as a good street tree resistant to dust, wind and smoke. (N. Tr.; X.)

LÓCZY, LAJOS (1849–1920), Hungarian geologist, who first scientifically described the mountains that connect the Kunlun chains with the northeast Indian chains behind the Red basin of Szechwan. Born at Pressburg (Bratislava) on Nov. 2, 1849, he studied at the Zürich polytechnic, obtaining his engineer's diploma in 1874, and from 1877 to 1880 traveled through India and China as geologist to the expedition of Count Bela Széchenyi which he described in his principal work (1890). In 1886 he became professor of geology at the University of Budapest, and in 1908 director of the Hungarian Geological institute. He completed geological researches in China, in Hungary and, during World War I, in Serbia. His researches concerning the steppe formations of the Gobi and the northern Hwang Ho territory were also of great importance. His other important work was a monograph on the Hungarian lake Balaton, in which the formations of the region are explained. His posthumous works include a new geological map of pre-World War I Hungary, and a book on the geology of west Serbia, which revolutionized the geological map of Serbia. He died at Balatonáracs on May 13, 1920.

LOD (LYDDA), an ancient town of Israel in the Plain of Sharon, 12 mi. S.E. of Jaffa. Pop. (1961) 19,012. It is a railway junction where the line along the coastal plain and that from Tel Aviv to Jerusalem meet. The main civil airport of Israel, home of the Israeli national airline, El Al, is 2 mi. N. of the town.

Lod is mentioned several times in the Old Testament (e.g., I Chron. viii, 12), and in the New Testament (Acts ix) it was the scene of Peter's healing of the paralytic. It was the seat of rabbinical schools after the destruction of the Temple (A.D. 70) and an early Christian settlement, traditionally the home of the martyr St. George, to whom an Orthodox church in the town is dedicated. It was a Roman colony, Diospolis, from A.D. 200, and had a Byzantine cathedral. After the Arab conquest, Lod was the chief town of Palestine until the capital was moved to Ramle. It was captured by the crusaders in 1099 and destroyed by Saladin in 1191. Until the establishment of the state of Israel its inhabitants were mainly Arabs. In the fighting during 1948 most of the Arabs fled and have been replaced by Jewish immigrants. (No. B.)

LODGE, HENRY CABOT (1850–1924), U.S. statesman and author, was born in Boston, Mass., on May 12, 1850. He graduated from Harvard college in 1871 and the Harvard Law school in 1875; was admitted to the Suffolk (Mass.) bar in 1876; and from 1876 to 1879 was instructor in American history at Harvard. He was a member of the Massachusetts house of representatives in 1880–81, and of the national house of representatives from 1887 to 1893. In 1893 he was elected U.S. senator from Massachusetts, a place he continued to hold for nearly 32 years.

His continuous service in the senate brought recognition during the closing years of the Roosevelt administration and under Taft as one of the most prominent of the Republican leaders. He was a member of the Alaskan Boundary Commission of 1903, and of the U.S. Immigration Commission of 1907. He served as permanent chairman of the Republican national conventions of 1900, 1908 and 1920. During the Republican-Progressive split which led to the election of Woodrow Wilson in 1912, Lodge maintained his personal friendship with Roosevelt, while he held true to his long-established principles of party regularity by supporting Taft, the Republican nominee.

In 1914 Lodge supported Wilson's demand for the repeal of the Panama tolls exemption, but lost confidence in him as a result of the president's handling of the Mexican problem in 1914, and

thereafter became one of his principal critics. He opposed Wilson's Caribbean policy and Colombia treaty, and desired the entrance of his country into World War I after the sinking of the "Lusitania." In Jan. 1916 he offered a resolution calling for armed intervention in Mexico.

With the entrance of the United States into World War I, Lodge called for united support of the president in all policies that might increase the war effort of the United States, although he opposed the Overman act, designed to organize war-making agencies. Wilson's peace policies were another matter. In 1915 and 1916 Lodge had advocated a league of nations and the principle of compulsory arbitration. But the conviction that the United States must always keep its word, which had led Lodge to support President Wilson's demand for the repeal of the Panama Canal tolls exemption in 1914, led him to oppose President Wilson's draft of the League. He felt that it embodied commitments which, when the moment came, the United States would not and could not keep. In 1918 Lodge became Republican floor leader of the senate and chairman of the foreign relations committee. He believed: that the League of Nations and the Versailles treaty should be separated; that the League covenant should be changed to provide that the United States should determine for itself what were and what were not domestic questions; that the United States should have more than mere equality of voting with the small countries; and that the League should not commit the United States to preserve the territorial integrity and political independence of League members except with the consent of congress. These beliefs were sustained in essence 25 years later when the senate dealt with the United Nations charter. Lodge succeeded in attaching to the treaty embodying the League of Nations reservations to carry out these beliefs. Wilson refused to accept the reservations. On March 19, 1920, the treaty, which had been reintroduced, having been previously defeated both with and without reservations, failed by seven votes to secure the necessary two-thirds vote of the senate, the Democratic senators voting against it at the wish of the president.

As the successful leader of the opposition to Wilson, Lodge's prestige was increased. He served as one of the four U.S. delegates at the Washington Conference on the Limitation of Armaments in 1921. His influence waned after he opposed Harding's proposal for joining the World Court, but he was re-elected to the senate in 1922 by a narrow margin. He died at Boston on Nov. 9, 1924, at the age of 74.

Senator Lodge was one of the chief congressional figures of the last decade of the 19th and the first two decades of the 20th centuries. Regarded by some as cold and distant in manner, he enjoyed the prestige indicated by his popular appellation, the "scholar in politics," and held the respect of his colleagues.

His literary production started early and continued until the close of his life. In 1873–76 he edited the *North American Review* with Henry Adams; and in 1879–81, with John T. Morse, Jr., he edited the *International Review*. In 1884–90 he was an overseer of Harvard college. His doctoral thesis at Harvard was published with essays by Henry Adams, J. L. Laughlin and Ernest Young, under the title *Essays on Anglo-Saxon Land Law* (1876). He wrote: *Life and Letters of George Cabot* (1877); *Alexander Hamilton* (1882), *Daniel Webster* (1883) and *George Washington* (2 vol., 1889), in the American Statesmen series; *A Short History of the English Colonies in America* (1881); *Studies in History* (1884); *Boston* (1891), in the Historic Towns series; *Historical and Political Essays* (1892); with Theodore Roosevelt, *Heroes and Tales From American History* (1895); *Certain Accepted Heroes* (1897); *The Story of the American Revolution* (2 vol., 1898); *The War With Spain* (1899); *A Fighting Frigate* (1902); *A Frontier Town* (1906); with J. W. Garner, *A History of the United States* (4 vol., 1906). He edited *The Works of Alexander Hamilton* (9 vol., 1885–86); *The Federalist* (1891); *André's Journal* (1903); and *Education of Henry Adams* (1918).

See William Lawrence, *Henry Cabot Lodge* (1925); John A. Garaty, *Henry Cabot Lodge: a Biography* (1953). (C. Sev.; H. C. L.)

LODGE, HENRY CABOT (1902–), U.S. senator, army officer and ambassador, was born in Nahant, Mass., July 5, 1902.

the grandson of Henry Cabot Lodge (q.v.). He studied in France, graduated from Middlesex school, Concord, Mass., in 1920 and Harvard university (*cum laude*) in 1924. Six of Lodge's ancestors served in the U.S. senate; his grandfather spearheaded the senate defeat of the Versailles treaty at the end of World War I. Lodge prepared for politics through an active career in journalism as a reporter for the *Boston Evening Transcript* and later as editorial writer for the *New York Herald Tribune*. He served two terms in the Massachusetts general court, 1933-36. In 1936 he was elected as a Republican to the U.S. senate from Massachusetts, and was re-elected in 1942. In 1941 and 1942 he went on extended active duty as a reserve officer with the U.S. army. In Feb. 1944 he resigned his senate seat to go on active duty with the U.S. army. He won re-election in 1946 but his senate seat was successfully challenged by Rep. John F. Kennedy in 1952. In that year Lodge had devoted much of his time to promoting the presidential campaign of Gen. Dwight D. Eisenhower. In 1953 President Eisenhower appointed him as permanent U.S. representative to the United Nations with ambassadorial rank and cabinet membership. He played a prominent role in many critical UN debates. In July 1960 the Republican convention nominated Lodge for the vice-presidency on a ticket headed by Vice-Pres. Richard M. Nixon, but in the November election the Nixon-Lodge ticket was defeated. In 1963-64 Lodge served as U.S. ambassador to the Republic of Vietnam (South Vietnam), returning home in 1964 when it appeared he might again win a place on the Republican ticket. In the summer of 1965 he returned to Vietnam as U.S. ambassador upon the retirement of Gen. Maxwell D. Taylor, who had replaced him in 1964. (C. P. C.)

LODGE, SIR OLIVER JOSEPH (1851-1940), English physicist who studied lightning and electricity and was a leader in psychic research, was born at Penkhill, Staffordshire, on June 12, 1851. He entered University college, London, in 1872, and obtained his doctorate in 1877. In 1875 he was appointed reader in natural philosophy at Bedford College for Women, and in 1879 he became assistant professor of applied mathematics at University college, London. Two years later he was called to the chair of physics in University college, Liverpool, where he remained until in 1900 he was chosen first principal of the new Birmingham university. He retired from this position in 1919. He was knighted in 1902. His original work includes investigations on lightning, the seat of the electromotive force in the voltaic cell, the phenomena of electrolysis and the speed of the ion, electromagnetic waves and wireless telegraphy, the motion of the ether near the earth and the application of electricity to the dispersal of fog and smoke. In addition to numerous scientific memoirs he wrote, among other works, *Lightning Conductors and Lightning Guards, Signalling Across Space Without Wires* (1897), *Modern Views of Electricity* (1889), *Electrons* (1907) and *The Ether of Space* (1909).

After 1910 Sir Oliver Lodge became increasingly prominent in psychic research. A strong believer in the possibility of communicating with the dead, he interested himself in a serious endeavour to reconcile science and religion. Among his publications dealing with this subject are *The Survival of Man* (1909) and *Raymond, or Life and Death* (1916). He died on Aug. 22, 1940, at Lake, near Salisbury.

See his autobiography, *Past Years* (1931)

LODGE, THOMAS (c. 1557-1625), English miscellaneous writer, chiefly remembered as a lyric poet and the author of the prose romance *Rosalynde* (the source of *As You Like It*), was a son of Sir Thomas Lodge, lord mayor of London in 1562. Born between May 1557 and April 1558, probably in London, he entered the Merchant Taylors' school in 1571, Trinity college, Oxford, in 1573 (graduating in July 1577), and Lincoln's Inn, London, in April 1578. His earliest work (c. 1579) is an unlicensed pamphlet in reply to Stephen Gosson, which Gosson answered in *Plays Confuted in Five Actions* (1582), censuring Lodge as "little better than a vagrant, looser than liberty, lighter than vanity itself." His mother's will (Sept. 1579) shows that he had soon wearied of the law and that his family found him spendthrift and not to be trusted with money.

An Alarum Against Usurers (1584) answered Gosson's attack on his character, and its exposure of the ways in which young heirs were lured into extravagance and debt almost certainly reflects personal experience. Lodge appended to the *Alarum* both a prose tale, *The Delectable Historie of Forbonius and Prisceria*, and a verse lament, *The Lamentable Complaint of Truth Over England*, and this collection foreshadowed the ways in which he chiefly employed his pen for the next 12 years: in verse (*Scillaes Metamorphosis*, 1589; *Phyllis*, sonnets and other poems, 1593; *A Fig for Momus*, eclogues, satires and epistles, 1595); in romances (*Rosalynde*, 1590; *Robert, Second Duke of Normandy*, 1591; *Euphuus Shadow*, 1592; *William Longbeard*, 1593; *A Margarite of America*, 1596); and in pamphlets (*Catharos*, 1591; *The Diuel Conjured*, 1596; *Wits Miserie, and the Worlds Madnesse*, 1596; *Prosopopeia*, 1596). In 1594 he published *A Spiders Webbe* (last heard of in the sale of John Hutton's books, 1764) and also two plays: *The Wounds of Civill War* and *A Looking Glasse for London and England* (the latter written in collaboration with Robert Greene).

As an alternative to this effort to maintain himself by writing, Lodge tried the career of adventurer. In the dedications to *Rosalynde* and *A Margarite of America* he mentions two voyages: the first to Terceira and the Canary Islands, and the second to South America with Thomas Cavendish on his disastrous last voyage (Aug. 1591); but neither seafaring nor literary enterprise served to keep him from poverty and he found a more secure profession when he graduated in medicine at Avignon (Jan. 1598). He was incorporated M.D. of Oxford in 1602 and practised in the Netherlands, where he took refuge at times as a recusant, and in London, where he died in 1625. Apart from *A Treatise of the Plague* (1603) and *The Poore Mans Talent* (a manual of domestic medicine, first printed by the Hunterian club, 1881), the works of the latter part of his life are translations: of selections from Luis de Granada (1601), of the works of Josephus (1602), of the prose works of Lucius Annaeus Seneca (1614), and of a French commentary on the *Semaine* of Du Bartas (1621).

Much of Lodge's work before 1600 was, in fact, surreptitious translation, the result partly of the stress laid on imitation in literary theory and partly of financial need, which encouraged mere compilation. The latter accounts for his poorest work (*Catharos* and *The Diuel Conjured*); the former gives importance and quality to his best. But in spite of some crude hackwork, there is no doubt of the genuineness of his literary interests and abilities. He had no gift for drama or for finding copy without the aid of books, but in most of his verse and some of his romances he showed a capacity for selection and assimilation which was creative. The first and last of his verse collections (*Scillaes Metamorphosis* and *A Fig for Momus*) are historically important as forward-looking in both matter and style. Many of his well-known lyrics first appeared in his romances where the link between poem and story encouraged some interesting experiments. Of the romances, *Rosalynde*, deservedly popular on its own account, is rivaled only by *A Margarite of America*, an arresting and dramatically plotted tale combining Senecan motives with the artifice of Euphuism and Arcadian romance in a manner which cannot be entirely credited to its source. This was, according to Lodge, "a historie in the Spanish tong" which he found in the Jesuit college at Santos during his visit to Brazil and, although doubt has sometimes been cast on this claim, the Jesuit library was certainly pillaged by Cavendish's followers. Of the prose pamphlets, *Wits Miserie* is, with the *Alarum*, the most readable for its Nashe-like cameos of London life. It is this ready response to fashions of one kind and another that makes Lodge's work important: having "so written as he had read," he is representative of an age schooled to draw both matter and style from literary models, and the variety of his work (to which he so often drew attention) gives him a place in the history of an unusual number of literary kinds.

BIBLIOGRAPHY.—*The Complete Works*, ed. by Edmund Gosse, 4 vol. (Hunterian club, 1883), includes everything but the translations. On Lodge's life, see C. J. Sisson, *Thomas Lodge and Other Elizabethans* (1933); Alice Walker, "The Life of Thomas Lodge," *Review of English Studies*, vol. lxx (1933-34).

(AE. WR.)

LODI, a town and episcopal see in the province of Milano, Lombardy region, Italy, is situated on the right bank of the Adda river, 30 km. (19 mi.) S.E. of Milan on the Milan-Rome railway. Pop. (1957 est.) 36,881 (comm.). It is an important centre of the dairy industry and is noted for its production of ceramics and wrought iron. Among buildings of special interest are the 12th-century Romanesque cathedral, which is being restored; the church of the Incoronata (1488-94); the Lombard Gothic church of S. Francesco, notable for its 12th- and 16th-century votive frescoes; the Ospedale Maggiore, established in the 15th century by a union of the town's hospitals and preserving the ancient cloister of the hospital of the Holy Spirit; and the Museo Civico and Laudense library, housing a series of illuminated 15th-century chant books.

Lodi was founded in the 5th century B.C. on the site of the suburb of Lodi Vecchio and obtained Roman citizenship in 89 B.C. Destroyed during the communal struggles of 1111 and by the Milanese in 1158, it was refounded on its present site by the emperor Frederick Barbarossa. Following the struggles between the Guelphs and Ghibellines it lost its independence to Milan (q.v.), with which its history was thereafter linked. On May 10, 1796, Napoleon defeated the Austrians at the battle of the bridge of Lodi, thereby gaining control of Lombardy.

LODZ, a *województwo* (province) in central Poland, bounded on the northeast by Warszawa province, on the northwest by Poznan and on the south by Kielce province. Area 17,065 sq.km. (6,589 sq.mi.); pop. (1960) 1,597,600.

The northern part of the province lies on the European plain and is drained by the Warta and its tributary, the Prosna. The southern part is in the Lodz highlands, formed of chalk marl. The region, formerly covered by forests and lakes, has been largely deforested (forests now occupy about 16% of the area) and cultivated despite poor soils. Agriculture has attained a high level, resulting in crop yields (rye, wheat, oats, barley, potatoes) larger than average for the country. Livestock breeding, particularly of sheep, pigs and cows, is well developed. Industry, the most important element in the province's economy, is centred mainly in and around Lodz city. Textile manufacture has long traditions there, with cotton as the most important branch. The city of Lodz (q.v.) has the greatest variety of factories, followed by Pabianice. Zgierz is mainly a centre for the wool industry and Aleksandrow for the production of knitted goods. Outside the Lodz industrial region, textile milling is carried on at Piotrkow Trybunalski (cotton) and Tomaszow Mazowiecki. The chemical industry is also important at Tomaszow Mazowiecki, and machine and furniture industries at Radomsko. Raw materials are provided by iron ore deposits near Leczyca, and brown coal is found in the Rogozno area.

Other towns in the *województwo* with populations exceeding 20,000 are Radomsko, Kutno, Zdunska Wola and Skierniewice. The Corpus Christi celebration in Lowicz (on the Bzura river, northeast of Lodz) is noted for its colourful local costumes. The whole area suffered very severe damage in World War I and had to face new economic problems. The German invasion and occupation of World War II brought fresh hardships to the population, especially the Jews. (T. K. W.)

LODZ is the second largest city in Poland and capital of Lodz *województwo* (province). The city itself has the status of an independent *województwo* and is the seat of a Roman Catholic bishopric. Pop. (1960) 708,400. It is situated on the northwestern edge of the Lodz highlands, on the watershed of the Vistula and Oder rivers 81 mi. S.W. of Warsaw. Lodz is an important railway junction on the Warsaw-Wroclaw line and has direct communications by rail and air with all the larger Polish towns. It is one of the largest centres of the cotton industry in the world.

Mentioned in 14th-century records as a village, Lodz acquired town rights in 1798. However, it remained for a long time a small insignificant settlement which had only 799 inhabitants in 1820. In that year, the government of the Congress kingdom decided to make it a centre for the textile industry and invited foreign weavers and artisans to settle there. After the customs barrier between Russia and the Congress kingdom was abolished in 1850, a great market for Lodz manufacture was opened up and by the end of

the 19th century Lodz had become the leading cotton centre in Poland. The rapid expansion of the town took place during that period, and by 1913 it had 506,000 inhabitants. Despite the severe damage sustained during World War I, Lodz maintained its importance as a cotton centre. Other industries developed include the manufacture of wool, silk, jute, hemp, clothing, metal, chemicals, leather, paper and food processing.

As a large industrial centre, Lodz was an important core of the working-class movements, and the scene of activity of Polish Communist leaders. Occupied by the Germans (who incorporated it into Wartheland and renamed it Litzmannstadt) during World War II, it was relatively undamaged and its factories were reactivated after 1945. By the early 1960s about 120,000 persons were employed in the textile mills, about half of whom were in the cotton trade.

Because the city developed mainly in the 19th century, it is of little historic architectural interest. Nearby villages and settlements were absorbed through its rapid territorial expansion, resulting in somewhat chaotic development. Some districts, such as Baluty, which despite its 100,000 inhabitants has only village rights, form a maze of factories, apartment houses, former mansions of factory owners and workers' cottages. The main thoroughfare is Piotrkowska street, once a highroad to Piotrkow. Although situated on a watershed, the city suffers from lack of water, which is supplied by subartesian wells and a pipeline from the Pilica river. After World War II there was a marked improvement in communal services such as drainage, hospitals, local transportation and public parks.

Lodz has become an important cultural centre since World War II, and contains eight higher educational establishments (the university and technical university, both founded in 1945, and schools of music, plastic arts, medicine, drama, film and economics). It also has a scientific society and a number of research institutes, several theatres, an opera house, a music hall and a philharmonic hall. (T. K. W.)

LOEB, JACQUES (1859-1924), German-U.S. pioneer in experimental biology, was born at Mayen (near Coblenz), Ger., on April 7, 1859, and studied at Berlin and Munich before receiving an M.D. degree from the University of Strasbourg in 1884.

His work in biology began at the universities of Würzburg (1886-88) and Strasbourg (1888-90), and at the Naples biological station (1889-91). In 1891 he went to the United States, becoming successively professor at Bryn Mawr college, Bryn Mawr, Pa. (1891-92), The University of Chicago (1892-1902) and the University of California, Berkeley (1902-10). In 1910 he became a member of the Rockefeller Institute for Medical Research in New York city and continued in that position until his death on Feb. 11, 1924, while vacationing in Bermuda. Much of his experimental work was done at the Marine Biological laboratory at Woods Hole, Mass.

Popular interest, attended by some controversy, was attracted to Loeb's experiments on artificial parthenogenesis, beginning in 1899, when he succeeded in bringing about the development of larvae of the sea urchin from unfertilized eggs by exposing them to controlled changes in their environment; this work was later extended to the production of parthenogenetic frogs, which he raised to sexual maturity. In addition to artificial parthenogenesis, Loeb is remembered for his work on the physiology of the brain, animal tropisms, regeneration and the duration of life. In his later years he made important contributions to the theory of colloidal behaviour, applying the principles of J. W. Gibbs and G. F. G. Donnan to the chemistry of proteins.

LOEFFLER, CHARLES MARTIN TORNOW (1861-1935), U.S. composer whose symphonic, choral and chamber music is distinguished by a poetic lyricism in an impressionist style, was born at Mulhouse, Alsace, France, on Jan. 30, 1861. The name Tornow was a pseudonym of his father, a German writer and agriculturist who was employed intermittently in Russia, Hungary and

Switzerland when Loeffler was a child. At the age of 14 he was sent to Berlin, where he studied the violin with Eduard Rappoldi and Joseph Joachim and music theory with Friedrich Kiel. Later he went to Paris, where his teachers were Joseph Massart in violin and Ernest Guiraud in composition. He emigrated to the U.S. in 1881 and in 1882 was engaged as a violinist in the Boston Symphony orchestra, resigning in 1903 to devote himself entirely to composition.

Almost all of Loeffler's symphonic works were first performed by the Boston Symphony orchestra. They include *The Nights in the Ukraine*, for violin and orchestra (1891); *Fantastic Concerto*, for cello and orchestra (1894); *Divertimento*, for violin and orchestra (1895); *La Mort de Tintagiles*, for two viole d'amore and orchestra (1898); *La Villanelle du Diable*, for organ and orchestra (1902); *Poem*, inspired by Verlaine's *La Bonne Chanson* (1902; revised in 1918); *A Pagan Poem*, after an eclogue of Virgil, for piano and orchestra (1907); *Hora Mystica*, for male chorus and orchestra (1917); and three *Irish Fantasies*, for voice and orchestra (1922). Of these, the most enduring and musically significant work is *A Pagan Poem*, a fine evocation of antiquity in modern harmonies impressionistically treated.

Loeffler's symphonic poem, *Memories of My Childhood*, subtitled *Life in a Russian Village* (1924), was awarded the Chicago North Shore Festival association prize. His *Canticum Fratris Solis*, for voice and chamber orchestra, on a text of Francis of Assisi and commissioned by the Coolidge foundation, was first performed at the opening concert of the Coolidge series at the Library of Congress, Washington, D.C. (1925). His *Evocation*, for women's voices and orchestra, was commissioned for the inauguration of Severance hall, Cleveland (1931).

Loeffler's choral works also include *By the Rivers of Babylon*, for women's chorus with organ, harp, two flutes and cello (1907), and *Beat! Beat! Drums!* to Walt Whitman's poem of that title, for men's chorus in unison, six piccolos, three saxophones, brass, drums and two pianos (1917). In smaller forms, Loeffler wrote two rhapsodies for oboe, viola and piano (1905); *Music for Four Stringed Instruments* (1917); a string quintet; a string sextet; a *partita*, for violin and piano; and several songs and piano pieces. Loeffler died in Medfield, Mass., on May 19, 1935.

See Carl Engel, "Charles Martin Loeffler," *The International Encyclopedia of Music and Musicians* (1958). (N. Sx.)

LOESS. Typical loess is a soft, porous rock, pale yellowish or buff in colour; one characteristic property is its capacity to retain vertical or even overhanging walls in the banks of streams. These vertical walls exist in China, where they stand in some places 500 ft. high and contain innumerable cave dwellings; ancient roads, too, have worn vertically downward deep into the deposit, forming trenchlike ways. This character in the loess of the Mississippi region in the United States gave rise to the name "bluff formation." A coarse columnar structure is often exhibited on the vertical weathered faces of the rock. Another characteristic is the presence throughout the rock of small capillary tubules, which appear to have been occupied by rootlets; these are often lined with calcite.

Loess usually is calcareous; some geologists regard this as an essential property, and when the rock has become decalcified, as it frequently is on the surface by weathering, they call it loessloam. In the lower portions of a loess deposit the calcium carbonate tends to form concretions, which on account of their mimetic forms have been called loess dolls. Bedding is absent from typical loess. The mineral composition varies somewhat in different regions, but the particles are always small; they consist of angular grains of quartz, fine particles of hydrated silicates of alumina, mica scales and undecomposed fragments of feldspar, hornblende and other rock-forming silicates.

In Europe and North America loess deposits are associated with the margins of the great ice sheets of the glacial period; thus in Europe they stretch irregularly through the centre eastward from the northwest of France, and are not found north of the 57th parallel. Most geologists are agreed that the true loess is an aeolian or wind-borne rock, formed most probably during periods of tundra or steppe conditions. But it seems clear that certain deposits classed as loess in western Europe do not really belong to this cate-

BENJAMIN SHAUB

LOESS FORMATION NEAR PENTICTON, B.C.

gory, being of alluvial origin and related to the brick earths of southeastern England. See **PLEISTOCENE EPOCH**; **WIND EROSION AND DEPOSITION**; *Dust Storms and Dust Deposits*; see also references under "Loess" in the Index. (F. J. P.)

LOEW, MARCUS (1870-1927), motion-picture executive and pioneer motion-picture theatre owner, was born May 8, 1870, in New York city, son of an Austrian immigrant. Leaving school at the age of nine to help support his family, he later found modest prosperity in the fur business.

Attracted by the new popularity of moving pictures Loew owned a chain of nickelodeons by 1905 and thereafter acquired many leading theatres for combined vaudeville and motion-picture exhibition.

In 1920 Loew's, Inc. purchased a production company named Metro Pictures Corp., and in 1924 the Goldwyn Pictures Corp. (from which Samuel Goldwyn had resigned) was absorbed. The name became Metro-Goldwyn-Mayer to represent the newly hired management group headed by Louis B. Mayer.

Loew died on Sept. 5, 1927, almost at the end of the silent film era. His estate was estimated at \$30,000,000. Neither flamboyant nor notably original, Loew was a show-business consolidator who made possible some of Hollywood's finest film achievements.

See Bosley Crowther, *The Lion's Share* (1957). (R. D. MACC.)

LOEWI, OTTO (1873-1961), German pharmacologist and Nobel laureate, was born at Frankfurt am Main on June 3, 1873, and was educated at Strasbourg and Munich universities. After becoming doctor of medicine in 1896, he devoted himself to physiological chemistry and pharmacology. In 1898 he was appointed assistant in the pharmacological institute at Marburg, and in 1901-02 he spent some months at University college, London, under E. H. Starling. Returning to Marburg, he was made titular professor of pharmacology in 1904, but in 1905 he went to Vienna as associate professor. From 1909 to 1938 he was professor of pharmacology in Graz, Aus. In 1940, he went to the United States, becoming research professor at the College of Medicine of New York university. He died in New York city on Dec. 25, 1961.

In 1936 Loewi and his lifelong friend Sir Henry Hallett Dale received jointly the Nobel prize for medicine for discoveries relating to the chemical transmission of nerve impulses. Between 1921 and 1926 Loewi and his colleagues showed that stimulation of the nerves in the perfused frog's heart led to the appearance of a substance which could readily inhibit a second heart receiving the perfused fluid from the first. This substance was finally shown to be acetylcholine, which had been first isolated from bio-

logical material by Dale in 1914. Loewi's experiments provided the first definite proof that chemical substances were concerned in the transmission of nervous impulses. He also carried out important researches on diabetes, digitalis, adrenaline and the vegetative nervous system, and in 1908 he devised "Loewi's test" for pancreatic function. (W. J. Br.)

LÖFFLER, FRIEDRICH AUGUST JOHANNES (1852-1915), German bacteriologist, one of the greatest names in the history of bacteriology, was born at Frankfurt an der Oder on June 24, 1852, the son of an army surgeon. He studied medicine at Würzburg university and at the Friedrich Wilhelm university in Berlin and, after serving in the Franco-German War, he obtained his M.D. degree at Berlin in 1874. After further service as an army doctor he became an assistant in the imperial health department (1879-84), where he was closely associated with Robert Koch. In 1888 he was appointed professor of hygiene at Greifswald and he was rector of that university, 1903-07. In 1913 he succeeded G. Gafky as director of the Robert Koch Institute for Infectious Diseases in Berlin. He died in Berlin on April 9, 1915.

In 1884 Löffler discovered *Corynebacterium diphtheriae*, the causal organism of diphtheria, and simultaneously with P. Roux and A. Yersin he indicated the presence of diphtheria exotoxin. Among his other notable achievements were the discovery of *Pfeifferella mallei*, the causative organism of glanders (1882), the discovery of the cause of swine erysipelas and swine plague (1885), and of *B. typhi murium* (1891). In collaboration with P. Frosch he found that foot-and-mouth disease is caused by a virus, the first occasion on which a virus was recognized as the cause of an animal disease. (W. J. Br.)

LOFOTEN AND VESTERÅLEN, a group of islands off the northwest coast of Norway, between 67° 30' and 69° 20' N. and between 12° and 16° 35' E., part of the *fylker* (counties) of Nordland and Troms. The extreme length of the group from Andenes, at the northern tip of Andøy, to Røst is about 255 km. (158 mi.); the aggregate area is about 5,128 sq.km. (1,980 sq.mi.). The largest island in the group, and indeed in Norway (excluding Svalbard), is Hinnøya, 2,198 sq.km. (849 sq.mi.). Pop. (1962 est.) 86,400.

The islands are separated from the mainland by the Vestfjord, the Tjeldsund and the Vågsfjord, and are divided into two sections by the Raftsund between Hinnøya and Austvågøy. To the west and south of the Raftsund lie the Lofoten Islands proper, of which the most important are Austvågøy, Vestvågøy and Moskenesøy; east and north of the Raftsund are the islands of Vesterålen, the chief being Hinnøya, Langøya and Andøy. The islands, which are of granite or gneiss, are a partially submerged mountain range and are lofty and rugged. The highest points are Møysalen (4,153 ft.) on Hinnøya and Higrastind (3,809 ft.) on Austvågøy near the Raftsund and the Trollfjord.

The long line of jagged peaks seen from the Vestfjord forms one of the most striking prospects on the Norwegian coast. The channels which separate the islands are narrow and tortuous, and generally of great depth; they have remarkably strong tidal currents, particularly the Raftsund and the famous Malstrøm or Moskenstrøm near Moskenes. Though the islands are situated within the Arctic circle, the climate is not rigorous and the coast is never frozen. The isothermal line which marks a mean January temperature of 0° C. (32° F.) runs south at the west side of the islands, passing east of Bergen onward to Göteborg, Sweden, and Copenhagen, Denmark. The prevailing winds are from the southwest and west, the mean temperature is 5° C. (41° F.) and the annual rainfall varies between 31 and 47 in. In summer the hills have only patches of snow. Much of the interior is bleak cranberry moor. Cattle are reared; grass and potatoes, but no cereals, are grown.

The characteristic industry is the cod fishery carried on along the east coast of the Lofotens in spring. During the season this employs many thousands from northern and some southwestern parts of Norway. The fish, dried on racks during early summer, ordinarily are exported from Bergen, especially to west African countries, and the fish heads are ground to fish meal. Industries

arising out of the fishery are the manufacture of cod-liver oil, canning and deep freezing. Herring is taken in large quantities in the fjords and surrounding waters of Lofoten and Vesterålen.

Svolvær, built on rocky islands off Austvågøy, is the chief town and principal port and trading centre; Kabelvåg is another fishing port. A church existed at Vågen (Kabelvåg) in the 12th century. Steamers connect the islands with Grimsby, England, Bergen and Kirkenes. A motor road across the Lofoten Islands was being constructed in the early 1960s. There are interisland ferry connections and ferry services between Hinnøya and the mainland via the Tjeldsund and the Vestfjord. During World War II Lofoten was the scene of British commando raids against the Germans. (L. H. Ho.)

LOG, MARITIME, an instrument for measuring the speed of a ship through the water. From its original meaning the term has come to be applied to the daily progress of a ship and also to the full written record of the voyage of a ship or flight of an airplane. The more exact term for such a written record is "logbook."

The oldest type of log of a practical nature was the "chip log." It consisted of the log chip, log reel, log line and log glass. The chip was a small piece of pie-shaped wood with a small lead weight on its circular side that caused it to float upright in the water and resist being towed. The log line was attached to the chip by a three-part bridge, one part fastened to a peg in the chip that could be pulled out by a jerk on the line when it was desired to haul in the chip. The part of the line, about 15 fathoms in length, next to the chip was called the "stray line" and its limit was marked by a piece of bunting. The remainder of the line was kept on the reel until used. It was marked off at intervals of 47½ ft. by pieces of cord, called "knots," worked into the log line. The log glass was a 28-second sandglass. The measurements of the log line and time were based on the following equation:

$$\frac{47\frac{1}{2} \text{ ft.}}{6,080 \text{ ft. (nautical mile)}} = \frac{28 \text{ sec.}}{3,600 \text{ sec. (hour)}}$$

To measure speed with the log, the chip with peg in place was dropped into the water from the stern and the log line was allowed to pay out from the reel. When the piece of bunting marking the end of the stray line unwound from the reel the sandglass was inverted. After 28 seconds had elapsed the number of knots that had passed overboard was counted. The number of knots that ran out in 28 seconds was the speed of the ship in nautical miles per hour. Some log lines were marked by bits of cloth to indicate fifths of a knot. For higher speeds a 14-second glass was used and the number of knots running out was multiplied by two.

The chip log gave the speed only at the time it was used. The desirability of knowing the distance run over an extended period of time brought into use many different types of patented rotating logs. In these the chip was replaced by a rotator, similar to a propeller, towed astern by a braided line. The revolutions of the rotator were transmitted by the braided line to a clockwork recording device on the stern of the ship where the result appeared on a dial as nautical miles made through the water. Because of the location of the recording dial on the stern rail, or taffrail, these logs are commonly known as taffrail logs. Many logs utilizing a rotator to indicate the distance traveled have been used, but all are liable to error if the rotator is fouled by floating weeds. At speeds greater than 15 knots in rough sea they are not accurate.

Logs installed in modern U.S. ships ascertain the ship's speed by means of a Pitot tube. A typical log built by the Pitometer Log corporation consists of a tube projecting through the bottom of the ship into undisturbed water. The tube is projected through a sea valve so it can be replaced if damaged or if the vessel enters shoal water. The tube has one forward-facing orifice called the dynamic-pressure orifice and two orifices at right angles to it called the static-pressure orifices. When the ship is stopped the pressure is the same in the dynamic and static connections but when the vessel steams ahead the dynamic pressure exceeds the static pressure. This difference in pressure varies as the square of the ship's speed.

Another part of the log consists of a small variable-speed electric motor driving a centrifugal water pump. In such a pump the dynamic pressure produced by the pump varies as the square of the speed of the motor. The pressure produced by the speed of the ship is exerted against a bellows which is balanced by pressure produced by the pump. Movement of the bellows operates the speed control of the motor making it exactly balance the pressure produced by the ship. With this accomplished, the speed of the pump and motor corresponds to the speed of the ship.

Attached to the shaft of the electric motor is a magneto which generates voltage proportional to the speed of the ship. This voltage is transmitted to the navigating bridge where it actuates the equivalent of a voltmeter whose graduated dial constantly indicates the speed of the ship in knots. The pump motor also drives a counting device which counts the revolutions made by the motor and transmits this information to the bridge as nautical miles steamed through the water. The dials on the bridge furnish the same information as the speedometer in an automobile. This type of log may also be arranged to draw a graph on a moving paper tape indicating the speed of the ship continuously during an entire voyage.

Since there is no continuous flow of water through the Pitot orifices the possibility of the openings being clogged with drifting material is slight, and since the actuating pressure is the difference between static and dynamic pressure there is no error caused by change in draft of the ship. (M. R. D.)

LOGAN, JAMES JOHN, also known by his Indian name **TAH-GAH-JUTE** (c. 1725–1780), was technically a Cayuga Indian because his mother was a member of that tribe. His father, Shikellamy, was purportedly a white Frenchman who had been taken by the Oneida as a child and had in manhood become a chief. Chief Shikellamy became Iroquois representative at the Delaware town of Shamokin in Pennsylvania and also a friend of the secretary of the colony of Pennsylvania, James Logan, whose name the chief's son assumed.

Logan moved to the Ohio valley after the French and Indian War and married a Shawnee. He was never a chief but he achieved renown among many Indian tribes, first because of his friendship with the white settlers, and later by reason of his ardent hatred of all white men. In 1774, at the beginning of Lord Dunmore's war against the Shawnee, Logan's family was treacherously killed by a frontier trader named Greathouse. That was when Logan declared war on the whites with such eloquence and with a particular venom directed against Capt. Michael Cresap, whom he blamed for the atrocious killing of his mother, sister and brother. From then until his death near Lake Erie at the hands of a relative, he pursued his vendetta, taking more than 30 white scalps. During the American Revolution, to further his hatred of Americans, he associated himself with the Mohawk auxiliaries of the British.

See Brantz Mayer, *Tah-Gah-Jute or Logan the Indian and Captain Michael Cresap*, 2nd ed. (1867). (J. H. H.)

LOGAN, JOHN ALEXANDER (1826–1886), U.S. senator and northern general during the American Civil War, was born in what is now Murphysboro, Ill., on Feb. 9, 1826. Without schooling until he was 14, he studied for three years in Shiloh college, then served in the Mexican War as a lieutenant of volunteers. He graduated from the law department of Louisville university in 1851 and began to practise law. He entered politics as a Douglas Democrat and was elected to the national house of representatives in 1858 and again in 1860. Logan resigned his seat in congress and entered the Union army as colonel of a regiment of volunteers that he had organized. He served under General Grant until the capture of Vicksburg, rising to the rank of major general of volunteers. He was commander of the army of the Tennessee at the battle of Atlanta but was later relieved of his command, apparently because General Sherman felt Logan did not pay enough attention to logistics.

After the war Logan, now a Republican, resumed his political career. He was a member of the house of representatives in 1867–71, and of the U.S. senate in 1871–77 and again from 1879 until his death. He was always identified with the radical wing of the

Republican party. His war record and his large personal following, especially in the Grand Army of the Republic (an organization of ex-soldiers that he helped to organize), contributed to his nomination for vice-president in 1884 on the ticket with James G. Blaine. When commander in chief of the Grand Army of the Republic in 1868–71, he successfully urged the observance of Memorial or Decoration day. He died at Washington, D.C., on Dec. 26, 1886. (N. A. G.)

LOGAN, a city of Utah, U.S., and seat of Cache county, is a college community and a distribution and marketing centre, on the Logan river, 80 mi. N. of Salt Lake City. Logan, with its many trees and gardens, is laid out at the mouth of scenic Logan canyon on terraces of prehistoric Lake Bonneville. It has an elevation of 4,535 ft. above sea level, with nearby Wasatch mountain peaks towering more than 5,000 ft. higher.

The city takes its name from the river, named for Ephraim Logan, a trapper of the 1820s. Believing Cache valley too cold for agriculture, Mormon colonizers did not arrive until 1855–56, and it was 1859 before Logan itself was founded; the city was incorporated in 1866. Grains and sugar beets were found to grow well, and subsequently dairying and stockbreeding thrived. A gray, twin-towered temple, completed in 1884, made Logan a Mormon religious centre. Utah State university, formerly the state agricultural college (founded 1888) has profoundly influenced the community. The Utah Northern railroad, built to Logan in 1873 and to Montana in 1877–81, was later incorporated into the Union Pacific system.

For comparative population figures see table in **UTAH: Population**. (D. L. M.)

LOGANBERRY (*Rubus loganobaccus*), a bramble fruit that originated in the garden of Judge J. H. Logan at Santa Cruz, Calif., in 1881. Raised from seed, it is thought to be a hybrid between the wild blackberry of the Pacific coast and the red raspberry.

BY COURTESY OF NEW YORK AGRICULTURAL EXPERIMENT STATION
LOGANBERRY (*RUBUS LOGANOBACCUS*)

berry. It is grown commercially in large quantities, especially in Oregon and Washington and in England and Tasmania. The loganberry or Logan is a vigorous, nearly trailing, blackberrylike plant with compound leaves of three to five leaflets, prickly canes and deep wine-red, tart, high-flavoured berries that separate from the stem as do the blackberries. The fruit is canned, frozen for preserve or pie stock, or made into wine. The Phenomenal, originated by Luther Burbank, is very similar to the Logan, but bears slightly larger fruit. The Young (Youngeberry), Boysen (Boysenberry), Pacific and Cascade are related berries that have the high aroma and flavour of the Logan and of the native blackberry. Research by M. B. Crane and P. T. Thomas in England and Waldo and Darrow in the U.S. department of agriculture indicates that the Logan probably originated as a hybrid of an octoploid blackberry fertilized with diploid pollen of a red raspberry. Hybrids of this kind are similar in appearance to the Logan. L. H. Bailey proposed the species name for this cultivated blackberry. See also **BLACKBERRY**. (J. R. Mac.)

LOGANIACEAE, a family of dicotyledonous plants including herbs, vines, shrubs and trees, chiefly tropical but with some representatives in temperate regions. More than 30 genera and about 600 species are recognized. The largest and most important genus is *Strychnos* in the tropics of both hemispheres, the seeds of various species, but especially those of *S. nux vomica*, yielding the drug and poison strychnine (q.v.). Many species of *Buddleia*, called butterfly bush, and one of *Gelsemium* (q.v.), the yellow or Carolina jasmine (jessamine) of the southeastern United States, are cultivated for ornamental purposes. (E. D. M.)

LOGANSPOORT, principal town and seat of Cass county, north-central Indiana, U.S., 70 mi. N.N.W. of Indianapolis, at the confluence of the Wabash and Eel rivers. It is a trading centre for an agricultural area comprising Cass, Carroll, Pulaski, Fulton, Miami and White counties, and an important shipping point for livestock and grain.

Manufactures include air-operated and hydraulic laboursaving equipment, die castings, electronic and electrical controls, automobile and airplane parts, metal stampings, screw products, hardwood lumber, fishing tackle, fire-fighting apparatus, mechanical rubber goods, metal springs and women's foundation garments.

Two of Logansport's public utilities, water and electricity, are municipally owned. A state mental hospital is located there.

Title to the land was acquired by treaty in 1826 from the Miami and Potawatomi Indians. The town was platted in 1828 and named after a Shawnee chief, the so-called Captain Logan (d. 1812), who was evidently an ally of the Americans in the War of 1812. It was incorporated as a town in 1831 and as a city in 1838. For comparative population figures see table in INDIANA: Population.

LOGARITHMIC DECREMENT is the measure of the rate of decay of any exponentially damped oscillation. It is the Napierian logarithm of the ratio of the first to the second of two successive current amplitudes in the same direction. The logarithmic decrement can also be considered as a constant of a simple radio circuit, being π times the product of the resistance by the square root of the ratio of the capacity to the inductance of the circuit. Measurement of logarithmic decrement is of great importance since it makes possible the determination of the equivalent resistance of the circuits under consideration, and also gives information concerning the lengths of the wave trains. The value of the sum of the decrements of two circuits may be obtained from their resonance curve.

LOGARITHMS. Invented in the early 17th century to speed up calculations, logarithms cut in half the time required for multiplication and were basic in numerical work for more than 300 years. The perfection of the desk calculating machine in the late 19th century and of the electronic computer in the mid-20th, made logarithms virtually obsolete for large-scale computation, though they are used in the 1960s for a few special purposes and indirectly as the basis for the slide rule. Meanwhile, however, interest has shifted from logarithms to the logarithmic function, which now holds an assured and significant place in both pure and applied mathematics.

The Nature of Logarithms.—The basic idea underlying logarithms may be seen in the following array of values:

$\frac{1}{8}$	$\frac{1}{4}$	$\frac{1}{2}$	1	2	4	8	16	32	64	Numbers
-3	-2	-1	0	1	2	3	4	5	6	Logarithms

Pick two numbers from the first row and multiply them; say, $2 \cdot 8 = 16$. The corresponding values in the logarithm row are 1, 3 and 4; notice that $1 + 3 = 4$. Multiplication of numbers in the first row corresponds to addition of the logarithms in the second row. Instead of multiplying 4 by 8 to get 32, look in the logarithm row to find 2 and 3 under numbers 4 and 8. Then add 2 and 3 to get 5 and look above the 5 to find 32. These two rows form a simple table of logarithms that can replace multiplication by addition. With a more complete table much tedious work of multiplication could be avoided. This is the basic idea that led to the invention of logarithms and made them such a valuable tool for computation.

To see the secret of the little logarithm table above, rewrite the numbers in the first row as powers of 2:

$\frac{1}{8}$	$\frac{1}{4}$	$\frac{1}{2}$	1	2	4	8	16	32	64	Numbers
2^{-3}	2^{-2}	2^{-1}	2^0	2^1	2^2	2^3	2^4	2^5	2^6	Numbers as Powers
-3	-2	-1	0	1	2	3	4	5	6	Logarithms

For example, $4 = 2^2$, $8 = 2^3$, $64 = 2^6$, $\frac{1}{2} = 2^{-1}$, and $\frac{1}{8} = 2^{-3}$ (see EXPONENT). These logarithms are seen to be the exponents when the numbers are expressed as powers of 2. In the equation $32 = 2^5$ the number 2 is called the base; 5 is the logarithm of 32 to the base 2 and is written $5 = \log_2 32$. More generally the two equations

$$\begin{aligned} x &= b^y \\ y &= \log_b x \end{aligned} \quad (1)$$

have the same meaning; the first serves to define the second. By this definition y is the logarithm of x to the base b if and only if $x = b^y$. The number x is also called the antilogarithm of y to the base b .

It is evidently easy to find logarithms of numbers that are simple powers of the base, and there are quite efficient methods for calculating logarithms of all numbers to as many decimal places as desired. Without going into these methods here, it is not hard to see that such logarithms could be approximated by elementary arithmetic and much labour. Suppose the logarithm of 5 to the base 2 (i.e., $\log_2 5$) is wanted. By equations (1) this means that a y is sought such that $5 = 2^y$. Since $4 = 2^2$ and $8 = 2^3$, the logarithm of 5 must lie between 2 and 3. Moreover, since 4 lies much closer to 5 than does 8, it might be guessed that the logarithm is between 2 and 2.5. Try 2.5 or $\frac{5}{2}$; does $5 = 2^{5/2}$? It does not, since taking the second power of both sides gives $5^2 = 2^5$ or $25 = 32$, which is false. But since the right side is too big, we know that $\frac{5}{2}$ is too large, and the search is narrowed. Now try 2.4 or $\frac{12}{5}$; does $5 = 2^{12/5}$? If it does then $5^5 = 2^{12}$ or $3125 = 4096$; thus 2.4 is too big. If patience holds, next try 2.3 or $\frac{23}{10}$. If $5 = 2^{23/10}$, then $5^{10} = 2^{23}$, or $9,765,625 = 8,388,608$. This time the left side is larger and therefore 2.3 is too small. The first two digits in $\log_2 5$ have been found; it begins 2.3 . . . Evidently with enough paper, pencils and time additional digits could be found by these methods. Actually, the early makers of logarithm tables used methods only a little less crude than these and by immense labours constructed very complete tables.

That multiplication of any numbers m and n can be accomplished by adding their logarithms (i.e., the logarithm of the product is the sum of the logarithms) can be expressed

$$\log_b mn = \log_b m + \log_b n \quad (2)$$

Experimentation with the table above can easily show that division of numbers can be accomplished by subtracting logarithms (i.e., the logarithm of the quotient is the difference of the logarithms) or

$$\log_b (m/n) = \log_b m - \log_b n \quad (3)$$

But this is not all; powers and roots can also be found with logarithms. For example, the cube of 4 is 64 (i.e., $4^3 = 64$), and from the table the logarithms of 4 and 64 are 2 and 6. Since $6 = 3 \cdot 2$, the logarithm of 4^3 can be found by multiplying the logarithm of 4 by 3. Study of the table will verify that the logarithm of a power can be found by multiplying the logarithm of the number by the index p of the power; i.e.,

$$\log_b n^p = p \log_b n \quad (4)$$

This means that to square a number, multiply its logarithm by 2; to cube multiply by 3, and so on.

Since logarithms transform multiplication into addition, division into subtraction, and taking powers into multiplication, it might be guessed that they would transform taking roots into division. This is the case; for example, to compute the square root of 16 find its logarithm (which is 4) and divide by 2. The result is 2 which is the logarithm of 4 as expected. In general, the logarithm of a root is the logarithm of the number divided by the index q of the root; i.e.,

$$\log_b \sqrt[q]{n} = \frac{1}{q} \log_b n \quad (5)$$

Since $\sqrt{n} = \sqrt[2]{n}$, square roots are given by $\log_b \sqrt{n} = \frac{1}{2} \log_b n$.

Logarithms work this way because they are exponents; and exponents are added for multiplying, subtracted for dividing, multiplied to take a power, and divided to take a root. These ideas may be expressed as laws of exponents:

$$\begin{aligned} b^x \cdot b^y &= b^{x+y} \\ b^x \div b^y &= b^{x-y} \\ (b^x)^y &= b^{xy} \\ \sqrt[q]{b^x} &= b^{x/q} \end{aligned} \quad (6)$$

The x and y in equations (6) may be thought of as logarithms. Indeed, suppose that $m = b^x$ (i.e., $\log_b m = x$) and $n = b^y$ (i.e., $\log_b n = y$). Then by the first equation (6) $mn = b^x \cdot b^y = b^{x+y}$. But by equations (1) this last is equivalent to $\log_b mn = x + y$. Replacing x and y by their values gives the value for equation (2) as desired.

In a similar way the other rules can be proved. Moreover, though these examples have applied to the base 2 and to simple integral values of the logarithms, the proofs hold for all numbers for which equation (1) has meaning and for which the laws of exponents hold. Incidentally, since $\sqrt[n]{m} = m^{1/n}$ by the last equation (6), equation (5) may be considered a special case of equation (4). Also, since $b^0 = 1$, then $\log_b 1 = 0$ and $\log_b(1/n) = -\log_b n$. Since $m/n = m(1/n)$, equation (3) may be viewed as a special case of equation (2).

Common Logarithms.—The most convenient tables for numerical calculations are those of logarithms to the base 10 (called common logarithms). Their great advantage is that if a table gives the logarithms of numbers between 1 and 10, the logarithms of all other numbers can be found very simply. For example, a five-place table of logarithms gives the log of 2.41 as 0.38202. (It will help to have such a table at hand for following this discussion.) Suppose the logarithm of 24.1 is wanted. Since $24.1 = 2.41 \cdot 10$, then $\log_{10} 24.1 = \log_{10} 2.41 + \log_{10} 10$. But $\log_{10} 10 = 1$; thus the logarithm being sought is 1.38202. In general, each time the decimal point is moved one place to the right, the number is multiplied by 10 and its common logarithm increases by 1. Moving the decimal point to the left divides the number by 10 and decreases the logarithm by 1. The following table gives the common logarithms of simple powers of 10:

$\frac{1}{10^3}$ 10^{-3}	$\frac{1}{10^2}$ 10^{-2}	$\frac{1}{10}$ 10^{-1}	1	10	100	1000	10,000	Numbers
-3	-2	-1	0	1	2	3	4	Numbers as Powers
								Common Logarithms

Numbers between those in this table have logarithms lying in between those given. Any two numbers with the same digits but with decimal points in different places, will have logarithms that differ by an integer.

Thus each common logarithm consists of two parts, an integer and a decimal less than 1. The integral part (called the characteristic) is determined by the position of the decimal point. It may be found from the common logarithm table above or by using the following simple rule. Count the number of places the decimal point must be moved to bring it just at the right of the leftmost nonzero digit, counting plus to the left and minus to the right; the result is the characteristic. For example, the characteristic for 2.41 is zero, since the decimal point is already at the right of the leftmost nonzero digit. The characteristic of 241 is 2, since the decimal point must be moved two places to the left; and the characteristic of 0.00241 is minus 3, since it must be moved three places to the right to bring it just to the right of the 2. The characteristics could also be found by noting that 2.41 lies between 1 and 10, 241 between 100 and 1000, and 0.00241 between $\frac{1}{1000}$ and $\frac{1}{100}$ in the table. Still another way to find the characteristic is to observe that it is equal to the exponent on 10 when the number is written in scientific notation (e.g., $2.41 = 2.41 \cdot 10^0$, $241 = 2.41 \cdot 10^2$, and $0.00241 = 2.41 \cdot 10^{-3}$).

The decimal part (the mantissa) of the common logarithm is found from the table, disregarding the decimal point. To find the mantissa corresponding to 2.41, 241 or 0.00241 look in, say, a five-place table under 241 and find 38202, with the decimal point omitted. To find the square root of 241, write $\log 241 = 2.38202$; then divide by 2 to give the log answer of 1.19101. This log answer corresponds to the final numerical answer of 15.528. The digits in the final answer are found by reading the five-place table backward. In this case the usual table fails to show the mantissa .19101; however, it does give mantissas of .19089 (corresponding to the digits 15520) and .19117 (corresponding to 15530). Interpolation by proportional parts gives the digits 15528 for the final answer. (Thus in most tables it is necessary to interpolate at this point. Interpolation is also required to find the logarithm of any number that is not in the table; see INTERPOLATION AND EXTRAPOLATION.) Then the decimal point is placed to correspond to the characteristic, which is 1 in this case. It can also be checked by rough estimate; here $15^2 = 225$ shows that the square root of 241 must be a little more than 15.

When the characteristic is negative, it cannot be written with

its minus sign in front of the mantissa without causing confusion. For example, the mantissa of the log of 0.00241 is .38202 and its characteristic is -3. Hence its logarithm is $-3 + .38202$, not -3.38202 . To avoid this difficulty it is customary to write the minus sign above the characteristic (e.g., $\bar{3}.38202$) or else to add and subtract 10 (e.g., $7.38202 - 10$). For example, to find the square root of .00241, write $\log 0.00241 = (7.38202 - 10)$; then divide by 2 to give $3.69101 - 5 = \bar{2}.69101$. Corresponding to the mantissa of .69101 the table gives the digits 49092. Since the characteristic is -2, the answer is 0.049092. If the cube root had been wanted, the logarithm would have been written as $27.38202 - 30$ so that 3 would evenly divide the negative part.

In doing logarithmic calculations it is convenient to make a form for the work and to carry out the calculations methodically. A typical problem for which logarithms are useful is $\sqrt[3]{34.865}$ (0.0000081139)/ $\sqrt{0.044561}$. First make a very rough estimate to check the result. Rounding off drastically and expressing in a form more convenient for estimating gives $\sqrt[3]{35} (8 \cdot 10^{-6}) / \sqrt{4 \cdot 10^{-2}}$ or approximately $3 \cdot 8 \cdot 10^{-6} / 2 \cdot 10^{-1}$; giving an estimate of $1.2 \cdot 10^{-4}$. It is not expected to find an answer equal to this, but the estimate gives some idea of the rough magnitude and helps discover gross errors. Now make out a form, look up logs and do the calculations as follows:

$$\begin{array}{r}
 \log 34.865 = 1.54239 \\
 \quad \quad \quad \div 3 \\
 \log \sqrt[3]{34.865} = 0.51413 \\
 \log 0.0000081139 = 4.90923 - 10 \\
 \log \text{ numerator} = 5.42336 - 10 \\
 \log 0.044561 = 8.64896 - 10 \\
 \quad \quad \quad \div 2 \\
 \log \text{ denominator} = 4.32448 - 5 \\
 \log \text{ answer} = 1.09888 - 5 = 4.09888 \\
 \text{answer} = 0.00012557
 \end{array}$$

This answer compares well with the initial estimate of 0.00012.

Natural Logarithms.—A vast field of additional possibilities is opened by considering the logarithmic function defined by $y = \log_e x$. An attempt to find its derivative (see CALCULUS, DIFFERENTIAL AND INTEGRAL) leads to the following calculations:

$$\begin{aligned}
 D_x \log_e x &= \lim_{h \rightarrow 0} \frac{\log_e(x+h) - \log_e x}{h} \\
 &= \lim_{h \rightarrow 0} \frac{1}{h} \log_e(1 + h/x) \\
 &= \lim_{h \rightarrow 0} \frac{1}{x} \cdot \frac{x}{h} \log_e(1 + h/x) \\
 &= \frac{1}{x} \lim_{h \rightarrow 0} \log_e(1 + h/x)^{x/h}
 \end{aligned}$$

Assuming that log is a continuous function (which it is), the problem reduces to finding the limit of $(1 + h/x)^{x/h}$ as h approaches zero; or what comes to the same thing, the limit of $(1 + 1/t)^t$ as t approaches infinity. This limit exists and is an irrational (also a transcendental) number e given exactly by the infinite series $e = 2 + \frac{1}{2}! + \frac{1}{3}! + \frac{1}{4}! + \dots + \frac{1}{n}! + \dots$, and by 2.71828 to five decimal places. The proof is tedious, but it can be found in many elementary calculus books.

This result leads to the equation $D_x \log_e x = (1/x) \log_e e$. The formula would be much simpler if the second factor on the right could be eliminated. But if b is taken equal to e , then $\log_e e = 1$ from equations (1). It is therefore convenient in calculus, and in all advanced mathematics, to use the logarithmic function to the base e . Logarithms to the base e are called natural logarithms and are usually designated by \ln without explicit use of the base. Thus

$$D_x \ln x = \frac{1}{x} \quad (7)$$

It is equation (7) that makes the logarithmic function so important. Without it there would be no function with a derivative of x^{-1} , since the formula $D_x x^n = nx^{n-1}$ does not yield $1/x$ in the right member for any value of n .

Though natural logarithms are less convenient than common

logarithms for numerical work, the natural logarithmic function is the key to finding numerical values of common logarithms. Formula (7) makes it possible to write $\ln(1+x) = x - x^2/2 + x^3/3 - x^4/4 + \dots + (-1)^{n+1}x^n/n + \dots$ (see TAYLOR'S THEOREM) which converges for $-1 < x \leq 1$ and could be used to calculate natural logarithms to as great a degree of accuracy as desired. Although the convergence of this series is quite slow, other very rapidly converging series can be derived from it. Once natural logarithms have been found, common logarithms can easily be obtained from the formula for change of base explained in the next paragraph.

Suppose two bases a and b , with $m = \log_a x$ or $a^m = x$. Then $\log_b(a^m) = \log_b x$. But $\log_b(a^m) = m \log_b a$, and $m = \log_a x$. Hence a general formula for changing from one base to another is $\log_b x = \log_a x \log_b a$. Letting $x = b$ and noting that $\log_b b = 1$ leads to the equation $\log_b a = 1/\log_a b$. Using this result, letting $b = 10$, and $a = e$, will lead to the following formula for transforming from natural to common logarithms: $\log_{10} x = \log_e x (1/\log_e 10)$. This means that to find the common logarithm simply multiply the natural logarithm by a fixed factor ($1/\log_e 10$) which equals 0.43439 to five-digit accuracy.

Existence of Logarithms.—It has been assumed here without proof that numbers have logarithms. That some numbers do is obvious in simple cases, and this discussion has argued for its general plausibility. However, in some cases there appear to be no logarithms. For example, since there is no real exponent such that $e^y < 0$, negative numbers would appear to have no logarithms. For definiteness consider only the base e and ask the question: For a positive number y does x exist such that $y = e^x$ (i.e., such that $x = \ln y$)? The graph of $y = e^x$ is a continuous, everywhere-increasing curve, as shown in fig. 1.

FIG. 1.—THE LOGARITHMIC FUNCTION AND ITS INVERSE, THE EXPONENTIAL FUNCTION

The proof of these statements is tedious, and an easier approach to the whole problem comes from making use of the equation (7). Since $1/x$ is a continuous function for all positive values of x , it

means that the definite integral $f(x) = \int_1^x \frac{dx}{x}$ exists for all posi-

tive x . From the fundamental theorem of integral calculus, the derivative of $f(x)$ is $1/x$. Since by equation (7) this is also the derivative of $\ln x$, it means that $\ln x$ and $f(x)$ differ by a constant, which must be zero since $\ln 1 = f(1) = 0$. Hence it can be written that

$$\ln x = \int_1^x \frac{dx}{x} \quad (8)$$

Figure 2 indicates the geometric meaning of this equation; i.e., $\ln x$ is the area under the graph of $y = 1/x$ between 1 and x .

Equation (8) may be taken as the definition of $\ln x$. It then follows immediately that $\ln x$ exists for positive x , and all its properties can be derived, including equations (1).

Extension to Complex Numbers.—So far $\ln x$ has been defined only for positive numbers. To extend the domain to negative real numbers (or, more generally, to complex values) requires a definition of complex exponents. This extension may be made by the following definition (see COMPLEX NUMBERS; TRIGONOMETRY): $e^{i\theta} = \cos \theta + i \sin \theta$, where i is the square root of -1 . If

now the definition $e^{a+iy} = e^a \cdot e^{iy}$ is added, exponents are defined for all complex values and can be proved to have all the expected properties, including those listed in equations (6).

Since $e^{i\pi} = \cos \pi + i \sin \pi = -1 + i \cdot 0 = -1$, then $\ln(-1) = i\pi$ by equations (1), and a logarithm of a negative number has been found. But things are not so simple as in the case of positive numbers and real logarithms. Since \sin and \cos have periods of 2π , then $e^{i(\pi + 2n\pi)} = \cos(\pi + 2n\pi) + i \sin(\pi + 2n\pi) = -1$ for any integral n , and hence $\ln(-1) = (2n+1)\pi i$ for any n . Thus the definition does not give a unique value to the logarithm. More generally, if the equation $x + iy = e^{c+id}$ is solved for c and d , it is found that $c + id = \ln(x + iy) = \ln \rho + i(\theta + 2m\pi)$ where $\rho = |x + iy|$, and θ satisfies $\cos \theta = x/\rho$, $\sin \theta = y/\rho$. Since this holds for any integral m , any complex number (and this includes real numbers) has an infinite number of complex logarithms. When the number is real, one of these is a real number; otherwise all logarithms are imaginary. The logarithmic function plays an important part in the theory of functions of a complex variable (see FUNCTION; DIFFERENTIAL EQUATIONS, ORDINARY).

History of Logarithms.—Though the germ of the idea goes back at least as far as a work by Michael Stifel (1544), logarithms were invented independently by John Napier, who published a table in 1614, and by Joost Bürgi, who came out with a table of antilogarithms in 1620. These men were motivated by the hope of simplifying such computations as those required in astronomy and their invention arose from comparing arithmetic and geometric progressions. Since the theory of exponents had not been worked out, the simpler modern approach was not available to them; this makes their discovery all the more remarkable. Napier's logarithms (Nap. log) given by $\text{Nap. log } y = 10^7 (\ln 10^7 - \ln y)$, were awkward for computations. For one thing, the logarithm decreased as the number increased. Napier and Henry Briggs soon thought of common logarithms, which immediately became popular.

Extensive tables of common logarithms were generally available before 1630. They were calculated by tedious repeated multiplications and the extraction of square roots. A clear construction of the theory came more slowly. As calculus developed, the logarithmic function appeared inevitably as the function that has a derivative of $1/x$. In 1668 Nicolaus Mercator derived the series for $\ln(1+x)$, which could have saved much of the work of preparing tables. It is easy to see why the logarithmic function attracted attention, quite apart from the use of logarithms in calculation. The differential equation $dy = y dx$, with a solution that is the exponential function (the inverse of the logarithmic function), states that the rate of change of y is proportional to y itself. Since this law of change is common to the growth of biological populations, the decay of radioactive substances, the accumulation of money at continuous compound interest and many other phenomena, the logarithmic function is inevitably involved in applied mathematics. Moreover the exponential function appears in an essential way in the solution of many differential equations, including all linear equations with constant coefficients.

Attempts to extend logarithms to negative numbers in the early 18th century led to considerable controversy among Gottfried Wilhelm Leibniz, Johann Bernoulli and Leonhard Euler. In 1742 William Jones gave the first systematic treatment of logarithms as exponents, and about 1747 Euler extended the theory to negative and complex numbers. However, it was not until the mid-19th century that the modern theory was completed and generally accepted.

FIG. 2.—THE NATURAL LOGARITHM AS AN INTEGRAL

BIBLIOGRAPHY.—The theory and use of logarithms in calculation is covered in such elementary textbooks as A. P. Hillman and G. L. Alexanderson, *Algebra and Trigonometry* (1963), as well as in the instructions accompanying tables. The exposition of the logarithm as a definite integral appears in a number of calculus books, and the multivalued logarithmic function is treated in books on functions of a complex variable. For the interesting history of the discovery and development of the concepts, see any general history of mathematics such as F. Cajori, *A History of Mathematics* (1919), and *History of Elementary Mathematics* (rev. ed. 1917; reissued 1950); V. Sanford, *A Short History of Mathematics* (1930), or D. E. Smith, *History of Mathematics*, 2 vol. (1957). See also the *Napier Tercentenary Memorial Volume* (1915), which is rich in historical detail.

LOGAU, FRIEDRICH, FREIHERR VON (1604–1655), German writer noted for his varied, witty and pithy epigrams, was born at Brockut near Nimptsch in Silesia in June 1604. He entered the service of the duke of Brieg, was made ducal councilor in 1644, and died at Liegnitz on July 24, 1655. His epigrams appeared in two collections, under the anagrammatic pseudonym "Salomon von Golaw," entitled *Erstes Hundert Deutscher Reimessprüche* (1638) and *Deutscher Sinngedichte drei Tausend* (1654). They satirize contemporary moral degeneration, court life, the German aping of French tastes, the falling away from religion, the lack of German national pride; and they reflect the sturdy independence and strength of character of their creator, who became, in 1648, a member of the Fruchtbringende Gesellschaft under the name of *Der Verkleinernde*. After his death he sank into obscurity; but his reputation was restored by G. E. Lessing and K. W. Ramler, who edited his *Sinngedichte* in 1759.

Hempel, *Die Kunst Friedrich von Logaus* (1917); S. H. Moore, "A Neglected Poet: Friedrich von Logau," *German Life and Letters*, vol. iii (1949–50).

(D. G. D.)

LOGGERHEAD (*Caretta caretta*), a large, reddish-brown carnivorous sea turtle (family Cheloniidae), reaching 300 lb. and a shell length of 3 ft., usually ranging in the warm coastal waters of the Atlantic and Pacific but straying widely outside tropical limits. The loggerhead musk turtle, of the family Kinosternidae, is a small land turtle (3 to 4 in. long) of the southeastern U.S. See also **TURTLE**.

LOGGIA, in architecture, is a room, gallery or hall open to the air on one or more sides, associated particularly with the Mediterranean and near eastern regions, where an open sitting room with protection from the hot sun was desired. Ancient Egyptian houses often had a loggia on their roofs, or an interior loggia facing upon a court. In medieval and Renaissance Italy the loggia was used frequently in conjunction with a public square or piazza. Thus the Loggia dei Lanzi, begun 1376, consists of three gigantic arches dominating one side of the main square of Florence. Another at Florence, the Loggia degli Innocenti, begun in 1419 after the design of Filippo Brunelleschi, marks the first appearance of the Renaissance revival of classic forms. The loggia was also an essential feature of villas and often had outstanding decoration, such as that of Raphael and his assistants in the Villa Farnesina at Rome.

(D. R. CN.)

LOGIA, a title used by New Testament scholars of the late 19th and early 20th centuries to describe a collection of "sayings of Jesus." Precedent for this use was sought in early Christian writings: early in the 2nd century Polycarp spoke of those "who pervert the *logia* of the Lord" and Papias said that "Matthew compiled the dominical *logia* in a Hebrew dialect"; Papias' own work was entitled *Expositions of the Dominical Logia*. It is highly doubtful, however, that these *logia* were "sayings of Jesus." Probably they were Old Testament passages regarded as oracles predicting the coming of the Messiah. When early Christians spoke of sayings of Jesus they used the word *logoi*; this is the term employed in the Greek "sayings of Jesus" discovered in papyrus fragments from Oxyrhynchus, Egypt, in 1897 and 1904. These "sayings," partly close to the Christian Gospels, partly quite different, were identified in 1952 by H. C. Puech as part of the apocryphal Gospel of Thomas, which consists of nothing but such sayings. It is an open question whether or not any of these

sayings can be regarded as based on genuine traditions independent of the Christian Gospels.

(R. McQ. G.)

LOGIC is the systematic study of the structure of propositions and of the general conditions of valid inference by a method which abstracts from the content or *matter* of the propositions and deals only with their logical *form*. This distinction between form and matter is made whenever we distinguish between the logical soundness or validity of a piece of reasoning and the truth of the premisses from which it proceeds, and in this sense is familiar in everyday usage. However, a precise statement of the distinction must be made with reference to a particular language or system of notation, a *formalized language*, which shall avoid the inexactnesses and systematically misleading irregularities of structure and expression that are found in ordinary (colloquial or literary) English and in other natural languages, and shall follow or reproduce the logical form—at the expense, where necessary, of brevity and facility of communication. To adopt a particular formalized language is thus to adopt a particular system or theory of logical analysis. And the formal method may then be characterized by saying that it deals with the objective form of *sentences* which express propositions, and provides in these concrete terms criteria of meaningfulness, of valid inference, and of other notions closely associated with these—among which we mention the notions of logical compatibility, analytic or logical truth, probable inference, and degree of confirmation.

The topics of inductive and probable inference, confirmation, and degree of confirmation belong to *inductive logic*, and are treated in the articles **INDUCTION** and **PROBABILITY**. In this article we confine attention to the remaining part of logic, or *deductive logic*. And we also omit treatment of *modal logic*, partly because this branch of deductive logic (though its beginnings go back to Aristotle) is still in a much more unsettled state than the remainder. But works on modal logic and modality are included in the bibliography.

FUNDAMENTALS OF MODERN LOGIC

The Propositional Calculus is, in most developments, the most elementary branch of logic, on which the others are based. It deals with the *sentence connectives*: "and," "or," "if," "not," "if and only if," and others of similar character. And in order to analyze and exhibit the logical properties of the connectives it employs also propositional variables p, q, r, \dots , which are to be thought of as variables replaceable by sentences.

In strictness the sentences by which the propositional variables are replaceable should be sentences of some appropriate formalized language (for instance, one of the functional calculi which are described below, or one of the systems of set theory). But for informal expository purposes we may employ also declarative sentences of the English language. Thus, with \supset as notation for "if ... then," the expression $p \supset q$ of propositional calculus may be thought of as having (by substitution for p and q) such instances as the following: "If you are not satisfied, we will refund your money," "If there are any survivors of the disaster, we will be able by prompt action to rescue some," "If Vidkun Quisling was a patriot, then *n*-butyl mercaptan is a perfume."

Of the various systems of notation which are in use, we here adopt a particular one for purposes of exposition. We shall use the sign \sim to denote *negation* (" $\sim p$ " to mean "not p "), the sign \supset to denote the *conditional* (" $p \supset q$ " to mean "if p then q " or "not both p and not q "), the sign \mid to denote *non-conjunction* (" $p \mid q$ " to mean "not both p and q "), juxtaposition or a dot to denote *conjunction* (" pq " or " $p \cdot q$ " to mean " p and q "), the sign \equiv to denote the *biconditional* (" $p \equiv q$ " to mean " p if and only if q "), the sign \vee to denote *inclusive disjunction* (" $p \vee q$ " to mean " p or q or both"), the sign \neq to denote *exclusive disjunction* (" $p \neq q$ " to mean " p or q but not both").—As the word "or" is ambiguous in ordinary English usage between inclusive disjunction and exclusive disjunction, the two signs \vee and \neq are provided for the two meanings of the word. The signs \supset and \equiv may often conveniently be read as "implies" (or "implies that") and "is equivalent to" respectively; but these readings must be employed with a certain caution not to misunderstand them, since the terms

implication and equivalence in ordinary usage often suggest that there is some relationship between the logical forms of the propositions or the sentences involved, whereas the truth of $p \supset q$ and of $p \equiv q$ (upon substitution of particular sentences for p and q) requires no such relationship. The connective \supset is also said to stand for *material implication*, distinguished from *formal implication* (defined below) and *strict implication* (a notion of modal logic). Similarly, \equiv is said to stand for *material equivalence*.

There are various ways in which some of the sentence connectives named above can be defined in terms of others. If the sign of nonconjunction (*Sheffer's stroke*) is taken as primitive, all the other connectives can be defined from this one. Also, if the signs of negation and inclusive disjunction are taken as primitive, all the others can be defined in terms of these; likewise if the signs of negation and conjunction are taken as primitive. But because of its special role in the rule of *modus ponens* and in the *deduction theorem* (see below), we here prefer to include \supset as one of the primitive connectives. Therefore we take \sim and \supset as primitive, and define the remaining connectives as follows:

$$\begin{array}{ll} [A|B] \rightarrow [A \supset \sim B] & [A \equiv B] \rightarrow [(A \supset B)(B \supset A)] \\ [AB] \rightarrow \sim[A|B] & [A \vee B] \rightarrow \sim[A \supset B] \\ [A \cdot B] \rightarrow \sim[A|B] & [A \equiv B] \rightarrow \sim[A \equiv B] \end{array}$$

Here the bold capital letters stand for arbitrary *well-formed formulas* of the propositional calculus (in the technical sense defined below)—or, when appropriate, for arbitrary well-formed formulas of some more extensive formalized language containing the propositional calculus as a part. And the arrow is to be read “is defined as,” or “is an abbreviation for.”

To formulate the propositional calculus explicitly, we first list the primitive symbols. These are the two connectives \sim , \supset , the two brackets $[]$, and an infinite list of propositional variables $p, q, r, s, p_1, q_1, r_1, s_1, p_2, \dots$. Any finite sequence of the primitive symbols is a *formula*. But as some formulas are evidently not meaningful, we define a subclass, the *well-formed formulas*, by the following *formation rules*: i. A propositional variable standing alone is a well-formed formula. ii. If A is a well-formed formula, $\sim A$ is a well-formed formula. iii. If A and B are well-formed formulas, $[A \supset B]$ is a well-formed formula.

Hereafter the bold capital letters shall stand for well-formed formulas of the propositional calculus—or later also well-formed formulas of other calculi or formalized languages—and the condition of well-formedness shall be understood without explicit repetition in every case.

In writing well-formed formulas we may abbreviate them by means of the definitions listed above; for instance, $[pq]$ is to be understood as an abbreviation of $\sim[p \supset \sim q]$, and $[p \equiv q]$ is to be understood as an abbreviation of $[[p \supset [\sim p \supset q]][\sim p \supset q] \supset p]$, i.e., as an abbreviation of $\sim[[p \supset [\sim p \supset q]] \supset \sim[[\sim p \supset q] \supset p]]$. Also well-formed formulas may be abbreviated by omission of brackets, in accordance with the three following conventions: (1) A bold dot is used to indicate that the scope of an omitted pair of brackets extends from the point where the dot appears, forward to the end of the formula; for example, $p \supset \cdot q \supset \cdot r \supset s$ is an abbreviation of $[p \supset [q \supset [r \supset s]]]$. (2) In restoring omitted brackets, and so far as not otherwise indicated by bold dots, the scope of a pair of brackets belonging to a conditional, a biconditional, or an exclusive disjunction is to be made wider than the scope of a pair of brackets belonging to an inclusive disjunction or a non-conjunction, and the latter in turn wider than the scope of a pair of brackets belonging to a conjunction; for example, $\sim p \vee q \cdot r \supset pq \vee rs$ is an abbreviation of $[[\sim p \vee [q \cdot r]] \supset [[pq] \vee [rs]]]$, i.e., of $[[\sim p \supset \sim[q \supset \sim r]] \supset [\sim[p \supset \sim q] \supset \sim[r \supset \sim s]]]$. (3) Where neither of the two preceding conventions applies, brackets are restored in accordance with the convention of association to the left; for example, $p \supset [q \supset r] \supset s \supset \cdot p \supset q \supset r$ is an abbreviation of $[[[p \supset [q \supset r]] \supset s] \supset [p \supset q] \supset r]$.

It must be understood that these abbreviations are not an actual part of the formalized language—the propositional calculus, or better, the particular formulation of propositional calculus which we are here stating. *E.g.*, the formalized language expresses

the inclusive disjunction of p and q by $[\sim p \supset q]$, and it is merely a device for our typographical convenience in writing about the formalized language, serving the purposes of brevity and perspicuity, that we sometimes abbreviate this as $[p \vee q]$, or as $p \vee q$. Especially, the rules of inference stated below are to be applied to the well-formed formulas themselves, and not to their abbreviations. As axioms of the propositional calculus we take the three following:

1. $p \supset q \supset \cdot q \supset r \supset \cdot p \supset r$
2. $\sim p \supset p \supset p$
3. $p \supset \cdot \sim p \supset q$

The assertion of the axioms is of course meant in the sense that they hold for any p, q , and r whatever. These particular axioms are due to Jan Łukasiewicz; they represent only one of many possible choices of axioms from which the same theorems follow by means of the two rules of inference below. Convenient verbal readings of the axioms, in which advantage is taken of the two readings of \supset , are as follows: 1. If p implies q , if q implies r , then p implies r . 2. If not- p implies p , then p . 3. p implies that, if not- p , then q .—Axiom 1 expresses the *transitive law of material implication*, and 2, the *law of Clavius*.

The *rules of inference* are the two following: I. *Rule of substitution*. From A , if B is any well-formed formula and b is a propositional variable, to infer the result of substituting B for b throughout A . II. *Rule of modus ponens*. From $[A \supset B]$, and A , to infer B .—In an application of I, we call A the *premiss*, and the result of the substitution the *conclusion*. In an application of II, $[A \supset B]$ is the *major premiss*, A is the *minor premiss*, and B is the *conclusion*.

A *theorem* of the propositional calculus is obtained from the axioms by a succession of applications of the rules of inference. Or more explicitly, a *proof* of a theorem is a finite sequence of well-formed formulas, of which the last one is the theorem in question, and each of which either is an axiom or is inferred from earlier formulas in the sequence by one of the two rules of inference; and a *theorem* is then any well-formed formula of which there is a proof.

For example, a proof may be constructed as follows, of the theorem $p \supset p$ (the *reflexive law of material implication*). Axiom 1 is first taken as premiss for an application of the rule of substitution. The substitution of $\sim p \supset p$ for q gives $p \supset [\sim p \supset p] \supset \cdot \sim p \supset p \supset r \supset \cdot p \supset r$, and from this by substitution of p for r (another application of the rule of substitution) is inferred $p \supset [\sim p \supset p] \supset \cdot \sim p \supset p \supset p \supset \cdot p \supset p$. This last is to be the major premiss in an application of *modus ponens*. Axiom 3 is the source of the minor premiss $p \supset \cdot \sim p \supset p$ (obtained by substituting p for q). Hence by *modus ponens* is inferred $\sim p \supset p \supset p \supset \cdot p \supset p$. Axiom 2 is then taken as minor premiss, and by another application of *modus ponens* is inferred $p \supset p$.

Other theorems are the following, which may be proved in the order named (though the proofs are generally not as easy as the example just given): $p \supset \cdot q \supset p$ (*law of affirmation of the consequent*), $\sim q \supset \sim p \supset \cdot p \supset q$ (*converse law of contraposition*), $\sim p \supset \cdot p \supset q$ (*law of denial of the antecedent*), $p \supset q \supset p$ (*Peirce's law*), $p \supset [p \supset q] \supset \cdot p \supset q$, $p \supset \cdot p \supset q \supset q$ (*law of assertion*), $p \supset [q \supset r] \supset \cdot q \supset [p \supset r]$ (*law of commutation*), $q \supset r \supset \cdot p \supset q \supset \cdot p \supset r$, $p \supset [q \supset r] \supset \cdot p \supset q \supset \cdot p \supset r$ (*self-distributive law of material implication*), $\sim \sim p \supset p$ (*law of double negation*), $p \supset \sim \sim p$ (*converse law of double negation*), $p \supset q \supset \cdot \sim q \supset \sim p$ (*law of contraposition*), $p \supset q \supset \cdot p \supset \sim q \supset \sim p$ (*law of reduction ad absurdum*), $\sim \cdot p \supset \sim p$ (*law of contradiction*), $p \vee \sim p$ (*law of excluded middle*), $pq \supset r \supset \cdot p \supset q \supset r$ (*law of exportation*), $p \supset [q \supset r] \supset \cdot pq \supset r$ (*law of importation*), $[p \supset q][p \supset r] \supset \cdot p \supset qr$ (*law of composition*), $\sim[pq] \equiv \sim p \vee \sim q$ and $\sim[p \vee q] \equiv \sim p \sim q$ (*De Morgan's laws*), $[p \supset q] \vee [q \supset p]$.

The last theorem in the foregoing list is sometimes spoken of as one of the “paradoxes” of material implication. It is not a paradox in the sense of an antinomy and is not inconsistent with important uses of \supset as expressing an implication relation. But it shows a divergence of the meaning of \supset from some of the

various meanings of the words "if ... then" in ordinary usage, and especially from their familiar but not very definite meaning in *conditions contrary to fact*. (To illustrate the latter we quote the conditional sentence, "If Vidkun Quisling had been a patriot, then *n*-butyl mercaptan would be a perfume," which must be distinguished from the corresponding sentence with a simple condition, quoted above, and indeed is clearly false.)

We shall speak of a *valid inference of the propositional calculus* not only within the propositional calculus itself but also within a more extensive formalized language containing the propositional calculus as a part. Namely a *substitution instance* of a theorem of the propositional calculus is any well-formed formula (of the more extensive formalized language) which results from a theorem of the propositional calculus by substituting specific well-formed formulas (of the more extensive language) for one or more of the propositional variables. And an inference from hypotheses A_1, A_2, \dots, A_n to a conclusion B is called a *valid inference* of the propositional calculus if B can be obtained from the hypotheses A_1, A_2, \dots, A_n , together with any number of additional premisses which are either theorems of the propositional calculus or substitution instances of theorems of the propositional calculus, by a succession of applications of the rule of *modus ponens* only.

Within the propositional calculus itself, if the inference from A_1, A_2, \dots, A_n to B is a valid inference of the propositional calculus, it can be shown that $A_1 \supset A_2 \supset \dots \supset A_n \supset B$ must then be a theorem of the propositional calculus. This general result, which is not a theorem of the propositional calculus but a theorem about the propositional calculus, is known as the *deduction theorem*. We shall see below that it can be extended to other more extensive formalized languages.—It is in the sense that the rule of *modus ponens* and the deduction theorem are both fulfilled that we are able to think of and use \supset as expressing an implication relation (in spite of the so-called paradoxes of material implication).

It is convenient to use such words as "theorem," "proof," "premiss," "conclusion" both for propositions, in whatever language expressed, and for formulas expressing propositions in some fixed formalized language. However, theorems about a particular formalized language are distinguished from theorems of the language by calling the former *metatheorems*. The deduction theorem is, e.g., a metatheorem of the propositional calculus, in contrast with, say, Peirce's law, which is a theorem of the propositional calculus. The metatheorems of a formalized language are said to belong to the *metatheory* of the language; and though we shall here treat the metatheory informally, it may itself be organized as a formalized language, which is then called a *meta-language* of the first language as *object language*. (See METATHEORY; SEMANTICS IN LOGIC.)

We go on to explain some additional metatheorems of the propositional calculus.

The two primitive connectives (hence all connectives definable from them) denote *truth-functions*: i.e., the *truth-value* (truth or falsehood) of $\sim p$ and of $p \supset q$ is uniquely determined by the truth-values of p and q . In fact the truth-value of $\sim p$ is falsehood when the truth-value of p is truth, and truth when the truth-value of p is falsehood. And (corresponding to the four theorems $p \supset q \supset p, p \supset \sim q \supset \sim p \supset q, \sim p \supset q \supset p \supset q, \sim p \supset \sim q \supset p \supset q$) the truth-value of $p \supset q$ is falsehood when the truth-value of p is truth and the truth-value of q is falsehood, and the truth-value of $p \supset q$ is truth in each of the three remaining cases. These determinations of the truth-value of $\sim p$ and of $p \supset q$ in terms of the truth-values of p and q , by using (say) 0 for truth and 1 for falsehood, may conveniently be displayed in the form of tables, which are then called *truth-tables* of negation and material implication.

The truth-tables enable us, given a well-formed formula of the propositional calculus and an assignment of a truth-value to each of its variables, to reckon out by a mechanical process the truth-value of the entire formula. (For example, if the values of p and q are both 1, the value of $p \supset q$ is 0, hence the value of $p \supset q \supset p$ is 1, hence the value of Peirce's law $p \supset q \supset p \supset p$ is 0.) If, for all possible assignments of truth-values to the variables, the calculated truth-value of the entire formula is 0, or truth, the

formula is said to be a *tautology*. The test whether a well-formed formula is a tautology is effective, since in any particular case the total number of different assignments of truth-values to the variables is finite, and the calculation of the truth-value of the entire formula can be carried out separately for each assignment of truth-values to the variables.

Now it may be verified that the three axioms, 1-3, given above are tautologies, and that the two rules of inference preserve tautologies in the sense that if the premiss or premisses are tautologies the conclusion must be a tautology. Hence every theorem of the propositional calculus is a tautology. By a more difficult argument it may be shown that every tautology is a theorem. Hence the truth-table test for tautologies (just described) can be used to decide, for any given well-formed formula of the propositional calculus, whether it is a theorem. This is a solution of the *decision problem* of the propositional calculus.

As corollaries of the solution of the decision problem, it follows that the propositional calculus is *consistent* in the sense that A and $\sim A$ cannot both be theorems, and *complete* in the sense that if A is not a theorem the addition of A as an extra axiom would result in inconsistency. By a different method it may be shown that the three axioms and the two rules of inference are *independent* in the sense that completeness is lost if any one of them is omitted.

In one sense the solution of the decision problem renders unnecessary the statement of axioms and rules of inference of the propositional calculus. For we might instead merely stipulate that every tautology shall be a theorem. However, this summary procedure provides no analysis of the logical relationships of the theorems among themselves, and no method by which to trace the consequences of a particular law of the propositional calculus or to formulate the situation which results when particular laws are rejected.

An example of the last is provided by the intuitionistic school of mathematics (see MATHEMATICS, FOUNDATIONS OF), which rejects the law of excluded middle and some other related laws of negation. To formulate the propositional calculus of mathematical intuitionism we may modify our above formulation as follows. Axiom 2 is replaced by the weaker axiom $p \supset \sim p \supset \sim p$, and there are then added the two further axioms: $p \supset q \supset p, p \supset [p \supset q] \supset p \supset q$. These axioms suffice for the intuitionistic laws of implication and negation. But as the definitions of conjunction and inclusive disjunction, given above, no longer serve to yield the characteristic properties of these connectives, it is necessary to introduce these two connectives as additional primitives, and to add also the axioms: $pq \supset p, pq \supset q, p \supset q \supset pq, p \supset p \vee q, q \supset p \vee q, p \supset r \supset q \supset r \supset p \vee q \supset r$. Then finally, after this last addition, the axiom $p \supset q \supset p$ may be dropped as not independent: in fact we can prove the theorem $p \supset p \supset q \supset p$ using only the axioms $p \supset q \supset pq, pq \supset p$, and the transitive law, and then $p \supset q \supset p$ follows by the axiom $p \supset [p \supset q] \supset p \supset q$.

Using this formulation of the intuitionistic propositional calculus we can show that not only the law of excluded middle is not a theorem, but also the law of Clavius, the converse law of contraposition, Peirce's law, and the law of double negation fail; but the introduction of any one of these as an added axiom would restore all the others as theorems. The "paradox" $[p \supset q] \vee [q \supset p]$ is still a consequence in the form $\sim[p \supset q] \supset q \supset p$, but not in the form containing the disjunction sign.

A **Logistic System, or Calculus**, is the purely formal part of a formalized language, taken in abstraction from any meaning or interpretation.

A logistic system is determined by giving its *vocabulary*, or list of primitive symbols, defining certain finite sequences of the primitive symbols to be *well-formed formulas*, listing certain well-formed formulas as *axioms*, and finally, stating *rules of inference*, by means of which a well-formed formula may on given conditions be *inferred* (as *conclusion*) from a set of one or more well-formed formulas (as *premisses*). A *theorem* of the logistic system is then defined to be a well-formed formula of which there is a *proof*, i.e., a finite sequence of well-formed formulas each of

which is either an axiom or inferred from earlier formulas in the sequence by one of the rules of inference, the last formula in the sequence being the theorem.

It is usually required that the set of rules of inference shall be *effective*, in the sense that there shall be a definite procedure or test by which, whenever a particular proposed conclusion from given premisses is before us, we can always actually decide whether the proposed inference is correctly made in accordance with one of the rules of inference; further that the set of axioms shall be effective, in the sense that there shall be a test by which, whenever a particular well-formed formula is before us, we can always decide whether it is an axiom (this requirement is satisfied when the axioms are a finite list which has been written out in full, but may also be satisfied in some cases of an infinite set of axioms). For these two requirements it will generally be necessary that the definition of well-formedness shall also be effective, in the sense that there shall be a test by which, whenever a particular formula is before us, we can always decide whether it is well-formed or not.

The reason for these requirements lies in the nature of the notion of a proof—as it is commonly understood, or as it is needed for the purposes of deductive logic (and, as a special case, in connection with mathematical proof). Namely it is a part of the notion of proof that a proof shall carry final conviction of the theorem proved (*i.e.*, of course, for any one who admits the axioms and rules of inference on which the proof is based). But without the requirements of effectiveness, it might happen that some one confronted with a proof of a theorem (and admitting the axioms and rules of inference) might nevertheless continue to doubt the theorem, because of doubt that the alleged proof actually is a proof in accordance with the axioms and rules. In such a case the proposer of the proof might fairly be asked to give a supplementary proof that it is a proof—and for purposes of deductive logic, this supplementary proof ought then to be treated as part of the whole proof, and included with it when the process of proof is formalized by the logistic method.

Though in the light of the requirements just explained, the notion of being a proof, in a particular logistic system, must be effective, it is clear that in general the notion of being a theorem may not be effective. For a well-formed formula is established as a theorem if a proof of it is found, but the failure of a particular investigator to find a proof may not necessarily mean that there is no proof to be found. It may indeed be possible in particular cases, by special methods, to establish as a meta-theorem that a certain well-formed formula is not a theorem. But this is not to say that there is a general test by which it is always possible, whenever a well-formed formula is given, to decide effectively whether or not it is a theorem.

Such a general effective test, by which to recognize any arbitrary given well-formed formula of a particular logistic system as being or not being a theorem, is called a *decision procedure* for the particular system. And the problem to find a decision procedure for a logistic system is called the *decision problem* of the system. As a particular example, we have seen (above) a solution of the decision problem of the full propositional calculus—or, as this particular logistic system is often called because of the character of the decision procedure, the two-valued propositional calculus. There exist also decision procedures for the intuitionistic propositional calculus, but none of them is as simple as that for the two-valued calculus. On the other hand there are logistic systems for which there is no solution of the decision problem, not merely in the sense that none has been found, but in the sense that it has been established as a meta-theorem that none can exist; examples of such systems (which will be discussed below) are the pure functional calculus of first order and of all higher orders—but the singular functional calculi of first and second orders (obtained from the corresponding pure functional calculi by omitting all functional variables which are more than singular) do have decision procedures.

As already indicated, the two-valued propositional calculus, the intuitionistic propositional calculus, and other systems to be introduced below may be considered as examples of logistic

systems. Each is namely a logistic system if regarded as determined by its vocabulary, its *formation rules* (defining the well-formed formulas of the particular system), its axioms, and its rules of inference, in abstraction from any meaning or interpretation. The logistic system becomes a formalized language if suitable meanings are given to its well-formed formulas, as is done informally in this article, and as may be done more accurately by providing definitions of *truth* and of *satisfaction* in the manner outlined in the article SEMANTICS IN LOGIC—or if *sense* as well as *denotation* is to be provided for (*see* the same article)—then by *rules of sense*, which are similar in character to the rules that compose the step-by-step definition of satisfaction, but which deal directly with the sense.

In general, if a logistic system has any sound interpretation, *i.e.*, any non-trivial way of giving meanings to its well-formed formulas in conformity with the formation rules, axioms, and rules of inference, it will have many such. Thus the same logistic system is common to many different formalized languages, and the results (theorems and metatheorems) for the logistic system hold equally for all the formalized languages, with appropriate changes of interpretation.—The point may be illustrated by the case of the pure functional calculus of first order (which is treated below), each different domain of individuals providing a different sound interpretation and hence a different formalized language.

The method which makes use of a formalized language, based upon a logistic system with explicitly stated formation rules, axioms, and rules of inference, is known as the *logistic method*. For the treatment of logic by this method, and especially to distinguish it from the less fully formal method of the older logic, the names *symbolic logic*, *mathematical logic*, *theoretical logic*, *logistic* have variously been used.

The Functional Calculus of First Order has, besides the notations of the propositional calculus (propositional variables and sentence connectives), also notations for *propositional functions* and the *quantifiers*.

To explain these new notations and their meanings we return to the notion of a *sentence*, which we have already employed in explaining the use of propositional variables.

A *propositional form* is an expression which is like a sentence except that it contains a number of *variables*, of any kinds, at places at which a corresponding sentence must contain fixed names or terms (*constants*)—the difference being that a sentence may be said simply to be true, or false, but a propositional form must rather be said to be true, or to be false, *for some system of values* of its variables. To turn to elementary mathematics for examples, " $49 + 36 = 85$ " and " $59 + 36 = 85$ " are sentences; the first one true and the second one false. But " $x + 36 = 85$ " is a singular propositional form, the adjective *singular* indicating that there is one variable of which values are to be considered. It may not be said to be true, or to be false, but rather it is true for the value 49 of x , and false for the value 59 of x ; or in a different terminology (*see* SEMANTICS IN LOGIC), " $x + 36 = 85$ " is *satisfied* by the value 49 of x , and by no other value of x . Similarly " $x^2 + y^2 = 85$ " is a binary propositional form, which is true for (satisfied by) the pair of values 7, 6 of x, y ; also true for the values 6, 7 of x, y ; also true for the values 2, 9 of x, y ; but false for the values 5, 8 of x, y . Even " $x + y - x = y$ "—being a binary propositional form rather than a sentence—must not be said just to be true, but to be true for all values of x, y .

In the foregoing examples the variables are numerical variables, *i.e.*, variables whose values are numbers. As examples of propositional forms containing variables of other kinds we may cite the quaternary form, "The distance from P to Q is less than the distance from R to S ," in which the values of the variables P, Q, R, S are points; and the singular form, "If x is a man, then x is mortal," in which the values of x are, say, concrete material things.

As an extreme case, and as a matter of terminological convenience, it is usual to consider a sentence as being a kind of propositional form, namely a propositional form in which the number of variables is 0 (or more correctly, as we shall see below

in which the number of free variables is ϕ).

As *universal quantifier* we shall use the notation consisting of a variable between parentheses; e.g., if the variable is x , the notation is (x) . The meaning is roughly indicated by saying that the universal quantifier corresponds to such English words as "all," "every"; or better indicated by saying that if a universal quantifier with some particular variable, say x , is prefixed to a singular propositional form whose variable is x , the resulting expression is a sentence, which is a true sentence if and only if the propositional form is true for all values of x . For example, " (x) [if x is a man, then x is mortal]" is a sentence (of a certain ill-defined language which we here use for temporary illustrative purposes only, a half-formalized version of English); and in fact, on the best available evidence, it is a true sentence. Again, " (x) [$x + 36 = 85$]" is a false sentence. However, a universal quantifier may be prefixed also, with analogous meaning, to a propositional form which is more than singular—or even, as a quite special but nevertheless allowable case, to a sentence. For example, " (y) [$x^2 + y^2 = 85$]" is a singular propositional form; and since, as it happens, this singular form is false for all values of x , the sentence " $(x)\sim(y)[x^2 + y^2 = 85]$ " is true. Again " (y) [$x + y - x = y$]" is a singular propositional form, true for all values of x ; and hence " $(x)(y)[x + y - x = y]$ " is a true sentence. And again " $(x)[49 + 36 = 85]$ " is a true sentence, because " $49 + 36 = 85$ " is a true sentence.

As *existential quantifier* we shall use the sign \exists followed by a variable, with parentheses enclosing both. The meaning corresponds roughly to that of the English word "some" (in the sense "at least one") or of the phrase "there is a." And if an existential quantifier with, say, the variable x is prefixed to a singular propositional form whose variable is x , the resulting expression is a sentence, which is true if and only if the propositional form is true for at least one value of x . The usage is otherwise similar to that of the universal quantifier, as a few examples will suffice to illustrate. If the meaning of the numerical variables x, y is such that they include the negative as well as the positive numbers among their values, " $(\exists y)[x + y = 85]$ " is a singular propositional form which is true for all values of x , and therefore " $(x)(\exists y)[x + y = 85]$ " is a true sentence. Also " $(\exists x)(\exists y)[x + y = 85]$ " is true. But " $(\exists y)(x)[x + y = 85]$ " is a false sentence, as there is no one number y such that $x + y$ is always 85 for every number x . On the other hand, " $(\exists y)(x)[x \times y = 0]$ " is true, as there is one number y , namely 0, such that $x \times y$ is always 0.

When a quantifier with a particular variable is prefixed to a propositional form, all occurrences of that variable in the resulting expression, including the occurrence of the variable in the quantifier itself, are said to be *bound* occurrences of the variable. Other occurrences of a variable, not bound, are called *free* occurrences. It is not excluded that a propositional form may contain both bound and free occurrences of the same variable; in fact, if A is a propositional form containing free occurrences of a certain variable, and B contains bound occurrences of that variable, then $[A \supset B]$ and $[B \supset A]$ each contain both bound and free occurrences of the variable. The variables which have bound occurrences in a given propositional form are called the *bound variables* of the form, and those which have free occurrences in it are called its *free variables*.

Having these last definitions, we must now go back and make the following amendment to our first account of propositional forms as it was given above. The variables of which values are to be considered in a propositional form are only the free variables of the form. And the form is said to be true or to be false for some system of values of its free variables (or in the other terminology, to be satisfied or not satisfied by a system of values of its free variables). A propositional form is *singular* if it has just one free variable, *binary* if it has just two different free variables, and so on, regardless of the number of bound variables. A sentence has no free variables; but it may have any number of bound variables, since the presence of bound variables does not prevent the sentence from expressing a particular proposition (making a particular statement or assertion).

For purposes of introductory exposition, we may describe a *propositional function* as obtained by abstraction from a propositional form. A binary propositional form, for instance, determines an association of a truth-value with each system—i.e., each pair—of values of its free variables, since for each such pair of values the propositional form is either true or false. And if this scheme of association of truth-values with pairs of things is taken as an abstract correspondence, independent of its expression in any particular language or of any particular notation for it, we have a binary propositional function. If, say, F is a binary propositional function thus obtained from a binary propositional form, and a, b is a pair of things of appropriate kind, we use the notation $F(a, b)$ to express that truth is associated with the pair a, b in the abstract correspondence; hence we have that $F(a, b)$ if and only if the propositional form is true for the system of values a, b of its free variables.

Similarly, if F is a singular propositional function obtained by abstraction from a singular propositional form, we have that $F(a)$ —or, as we shall say in words, that F holds of the argument a —if and only if the propositional form is true for the value a of its free variable. And generally, if F is an n -ary propositional function obtained by abstraction from an n -ary propositional form, we have that $F(a_1, a_2, \dots, a_n)$ —or in words, that F holds among the arguments a_1, a_2, \dots, a_n —if and only if the propositional form is true for the system of values a_1, a_2, \dots, a_n of its free variables.

A propositional function obtained by abstraction from a propositional form must not be identified with the latter, since in fact different propositional forms may well sometimes determine the same scheme of association of truth-values with ordered sets of n arguments, that is, the same propositional function. A propositional form must also not be used as a name of the corresponding propositional function, since the propositional function is a fixed particular thing, of which no expression containing free variables may serve as name; but the propositional form with an abstraction operator prefixed (see ABSTRACT AND ABSTRACTION) is rather to be used as a name of the propositional function, where the abstraction operator, like the quantifiers, has the effect of changing free variables to bound variables. For example, if A is a singular propositional form with free variable x , then $\hat{x}A$ or λxA (we shall here use the latter) is a name of the singular propositional function obtained from A by abstraction.

Moreover, propositional functions must not be limited to those obtained or obtainable from propositional forms by abstraction, especially if only propositional forms belonging to one particular (formalized or other) language are considered. But abstractly, any scheme of the sort described (i.e., by which truth-values are made to correspond to ordered sets of n arguments) is a propositional function, however it may have come to be known, or even if the particular propositional function never comes to be known.

It should be added that the term "propositional function" is used with various meanings and shades of meaning by different writers, the terminology being not yet fixed. Sometimes "propositional function" is used to mean what we here call a propositional form, or in a way that involves confusion between this and one of the more abstract meanings.

But as the term has just been explained, and as it will be used in this article, a singular propositional function may be identified with a class or set, and a binary propositional function may be identified with a (binary) relation. Thus the notation " $F(a)$ " may be read not only as " F holds of the argument a " but also as " a belongs to the class F "; and " $F(a, b)$ " may be read as "the relation F holds between a and b " or " a bears the relation F to b ."

In the functional calculus of first order, the arguments of the propositional functions considered are taken as belonging to a fixed domain, the domain of *individuals*. Any well-defined class of things may be chosen as the domain of individuals, subject to the one restriction that it shall not be empty, i.e., that there shall be some individuals. (And we shall here use the term *domain of individuals* to mean a domain that is not empty.) But a definite domain of individuals must be fixed upon in order to have an in-

terpretation of the calculus and thus a particular formalized language.

Individual constants are symbols used as names of particular individuals. *Individual variables* are variables which have individuals as values, and which are therefore under appropriate circumstances replaceable by individual constants, in the same sense in which propositional variables (*see above*) are replaceable by sentences. Likewise, *n-ary functional constants* (or *n-ary predicates*, as they are also called) are symbols used to denote particular *n-ary* propositional functions. And *n-ary functional variables* are variables which have *n-ary* propositional functions as values, and which are therefore under appropriate circumstances replaceable by *n-ary* functional constants.

In our present formulation of functional calculus of first order we shall use as individual variables the letters $x, y, z, t, u, v, w, x_1, y_1, z_1, t_1, u_1, v_1, w_1, x_2, \dots$; we shall use as propositional variables the same which were used in the propositional calculus; as singular functional variables, $F^1, G^1, H^1, F_1^1, G_1^1, H_1^1, F_2^1, \dots$; as binary functional variables $F^2, G^2, H^2, F_1^2, \dots$; and so on for ternary functional variables, quaternary functional variables, \dots . The superscripts 1, 2, 3, \dots upon the functional variables, distinguishing them as singular, binary, ternary, \dots , are necessary in principle, especially in connection with the semantics of the language, in order to avoid using the very same symbol with two or more different meanings. But in practice, and as an abbreviation, the superscript may usually be omitted as being uniquely determined by the context.

The *alphabetic order* of the individual variables is the order in which they were just listed, *i.e.*, x, y, z, t, u , and so on. Likewise in the case of the functional variables of each kind, the *alphabetic order* is that in which they were just listed.

The name *functional calculus of first order* is applied to any one of many (different but closely related) logistic systems, which differ only in regard to the list of primitive symbols. All of these systems include as primitive symbols a sufficient list of sentence connectives and quantifiers, and also the notation which was explained above (consisting of parentheses and commas) for the holding of a propositional function, among certain arguments or of a certain argument. The individual variables are, further, always among the primitive symbols. And the remaining primitive symbols must belong to one of the categories of propositional variables, functional variables, individual constants, or functional constants.

The *pure functional calculus of first order* has all the propositional variables and functional variables as primitive symbols, and no individual constants or functional constants. An *applied* functional calculus of first order contains individual constants or functional constants or both, among its primitive symbols. A *simple applied* functional calculus of first order is an applied functional calculus of first order in which there are no propositional or functional variables among the primitive symbols.

As primitive connectives and quantifiers for functional calculus of first order we shall here use the signs of negation and material implication, and the universal quantifier. However, as in the case of the propositional calculus, other choices are possible. (And in fact the article SEMANTICS IN LOGIC makes use of negation, inclusive disjunction, and universal quantification as primitive.)

The well-formed formulas are defined by formation rules, which we here state in such a form that they can be used equally for any of the different functional calculi of first order: i_0 . A propositional variable standing alone is a well-formed formula. i_1 . If f is a singular functional variable or a singular functional constant, and x is an individual variable or an individual constant, then $f(x)$ is a well-formed formula. i_2 . If f is an n -ary functional variable or an n -ary functional constant, and x_1, x_2, \dots, x_n are individual variables or individual constants or both, not necessarily all different, then $f(x_1, x_2, \dots, x_n)$ is a well-formed formula. ii . If A is a well-formed formula, $\sim A$ is a well-formed formula. iii . If A and B are well-formed formulas, $[A \supset B]$ is a well-formed formula. iv . If A is a well-formed formula, and x is an individual variable, then $(x)A$ is a well-formed formula.

Every well-formed formula in a functional calculus of first order is a propositional form or a sentence, as in the case of the propositional calculus and other formalized languages which we shall consider in this article. However, there are many important cases (not here treated) in which the well-formed formulas include formulas that are not propositional forms or sentences but, *e.g.*, names of propositional functions, or of numbers, or of concrete material things. And indeed it would not be unnatural, in the case of the functional calculus of first order, to take the individual constants, individual variables, functional constants, and functional variables to be well-formed formulas when they stand alone—although the standard convention, in this particular case, is rather that which is given by the formation rules above.

In abbreviating well-formed formulas of functional calculus of first order, we omit superscripts upon functional variables (as already described), we use the same conventions regarding omission of brackets which were explained above in connection with the propositional calculus, we use the same definitions (of $[A, B]$ etc.), also the definition of the existential quantifier,

$$(\exists x)A \rightarrow \sim(x)\sim A,$$

where x is an individual variable, also further the following definitions:

$$\begin{aligned} [A \supset_x B] &\rightarrow (x)[A \supset B] \\ [A =_x B] &\rightarrow (x)[A = B] \\ [A \wedge_x B] &\rightarrow (\exists x)[AB] \\ [A \supset_{xy} B] &\rightarrow (x)(y)[A \supset B] \\ [A =_{xy} B] &\rightarrow (x)(y)[A = B] \\ [A \wedge_{xy} B] &\rightarrow (\exists x)(\exists y)[AB] \end{aligned}$$

and likewise with three or more subscripts x, y, z , etc., where the subscripts x, y, z, \dots must be individual variables and all different in each case.

The relation between propositional functions that is expressed, in accordance with the above definitions, by the sign \supset followed by one or more individual variables as subscripts is called *formal implication* (the standard term, though the adjective "formal" has here a rather different meaning from that which we have given to it elsewhere). For example, in the case of singular propositional functions, $F(x) \supset_x G(x)$ (*i.e.*, the well-formed formula which is thus abbreviated) is said to express that F formally implies G , or in different words, that $F(x)$ formally implies $G(x)$, with respect to x ; and in the case of binary propositional functions, $F(x, y) \supset_{xy} G(x, y)$ expresses that F formally implies G , or that $F(x, y)$ formally implies $G(x, y)$ with respect to x and y . In similar fashion the sign $=$ followed by individual variables as subscripts is said to express the relation of *formal equivalence* between propositional functions.

Now by including rules of substitution among the rules of inference, it is possible to make a formulation of the pure functional calculus of first order in which the number of axioms is finite. But because of rather complicated explanations which would be necessary in connection with one of the substitution rules in particular (that for functional variables) we here employ a formulation without rules of substitution and with an infinite number of axioms. The infinite set of axioms is then given by means of five axiom schemata, which we shall state. And this procedure has the further advantage that the same five axiom schemata (though not the same infinite set of axioms) are sufficient for any one of the other first-order functional calculi, as well as for the pure calculus.

The first three of the axiom schemata are as follows:

$$1. A \supset B \supset . B \supset C \supset . A \supset C$$

$$2. \sim A \supset A \supset A$$

$$3. A \supset . \sim A \supset B$$

The first axiom schema means, *e.g.*, that if A, B, C are any well-formed formulas of the first-order functional calculus under consideration (possibly all three different, or possibly some of them the same), then $A \supset B \supset . B \supset C \supset . A \supset C$ is an axiom. In the case of the pure first-order functional calculus, two of the axioms which are instances of the first axiom schema are, for instance, $p \supset q \supset . q \supset r \supset . p \supset r$ and $\sim q \supset [F(x) \supset G(x)] \supset . F(x) \supset G(x) \supset (x)H(x, y) \supset . \sim q \supset (x)H(x, y)$.

The fourth axiom schema is the following:

4. $A \supset x.B \supset . A \supset (x)B$, provided that x is an individual variable which is not a free variable of A .

In order to state the fifth axiom schema, it is necessary first to explain another metatheoretic notation. In using bold capital letters to stand for well-formed formulas, we shall sometimes add after the letter an indication of one of the free variables it may contain, providing by this device a convenient notation for the process of substituting one free variable for another. For example, if we use Ax to stand for a well-formed formula which has or may have x as a free variable, then Ay shall stand for the well-formed formula obtained from Ax by substituting y for all free occurrences of x in Ax —provided, however, that if any of the free occurrences of x in Ax are in a well-formed part of Ax of the form $(y)C$, then Ay shall be obtained from Ax by first substituting z for all bound occurrences of y in Ax and then substituting y for all free occurrences of x in Ax , z being the first individual variable in alphabetic order that does not occur in Ax . In the special case that Ax does not actually contain x as a free variable, Ay is the same as Ax . And the same notation may be used also for substitution of a constant for a free variable, so that, e.g., if a is any individual constant, Aa stands for the result of substituting a for all free occurrences of x in Ax .

Employing this notation, we state the fifth axiom schema:

5. $(x)Ax \supset Ay$, where x is an individual variable, Ax is a well-formed formula which may have x as a free variable, and y is an individual variable or an individual constant.

To use the case of the pure functional calculus of first order for illustration, following are some examples of instances of axiom schema 5, which are therefore axioms:

$$\begin{aligned} (x)F(x) &\supset F(y) \\ (y)F(y) &\supset F(y) \\ (y)F(x, y) &\supset F(x, x) \\ (x)(y)F(x, y) &\supset (x)F(y, x) \\ (x)[F(x) \supset G(x)] &\supset . F(x) \supset G(x) \\ (x)[F(x) \supset G(x)] &\supset . F(x) \supset G(x) \end{aligned}$$

To complete the formulation of first-order functional calculus as a logistic system (whether the pure first-order functional calculus or one of the others), it remains only to state the rules of inference. These are the two following: II. *Rule of modus ponens*. From $A \supset B$ and A , to infer B . III. *Rule of generalization*. From A , if x is any individual variable, to infer $(x)A$.

In an application of the rule of generalization, the variable x is said to be *generalized upon*.

Where A_1, A_2, \dots, A_n, B are well-formed formulas of one of the functional calculi of first order, we say that the inference from the hypotheses A_1, A_2, \dots, A_n to the conclusion B is a *valid inference of first-order functional calculus* if B can be obtained from the hypotheses A_1, A_2, \dots, A_n , together with the axioms of the particular functional calculus of first order, by a succession of applications of the two rules of inference, *modus ponens* and generalization, subject to the restriction that no variable shall be generalized upon which is a free variable of any of the hypotheses A_1, A_2, \dots, A_n . (The distinction which is made here between "hypotheses" and "premisses" may be ignored only if the hypotheses are without free variables.)

For example, from the single hypothesis $F(x)$ there is a valid inference to the conclusion $(y) \sim F(x) \supset F(y)$, namely by taking as major premiss the axiom $F(x) \supset . \sim F(x) \supset F(y)$, which is an instance of axiom schema 3, and applying *modus ponens*, and then generalizing upon y . On the other hand there is no valid inference from the hypothesis $F(x)$ to the conclusion $(x)F(x)$, and indeed it is informally evident that the definition ought not to allow this as a valid inference—i.e., from the hypothesis that a particular individual x belongs to the class F , it does not in general follow that all individuals belong to the class F .

There is not space to treat in detail particular theorems and valid inferences of first-order functional calculus. But some of the simplest of the latter will be mentioned below in the discussion of traditional logic. And we list here the following important metatheorems (omitting their proofs, with one exception):

The Deduction Theorem.—If there is a valid inference (of first-

order functional calculus) from the hypotheses A_1, A_2, \dots, A_n to the conclusion B , there is a valid inference also from the hypotheses A_1, A_2, \dots, A_{n-1} to the conclusion $A_n \supset B$. Hence if there is a valid inference from the hypotheses A_1, A_2, \dots, A_n to the conclusion B , then $A_1 \supset . A_2 \supset . \dots A_n \supset B$ is a theorem. And, as a special case, if there is a valid inference from the single hypothesis A to the conclusion B , then $A \supset B$ is a theorem.

Tautologies.—Every *tautologous* well-formed formula is a theorem, i.e., every well-formed formula which is a tautology of the propositional calculus or is obtained from such a tautology by substitutions for the propositional variables.

Substitutivity of Equivalence.—If $M \equiv N$ is a theorem, if A is a theorem, and if B is obtained from A by replacing M by N at one or more places (not necessarily at all occurrences of M in A), then B is a theorem.

Reduction to Prenex Normal Form.—There is an effective procedure by which, given a well-formed formula A of a first-order functional calculus, there may be found a well-formed formula B of the same first-order functional calculus, such that $A \equiv B$ is a theorem, and B is in *prenex normal form*—i.e., B consists of a quantifier-free well-formed part, called the *matrix*, and of a preceding part which is called the *prefix* and which consists of a number of universal and existential quantifiers prefixed to the matrix, subject to the condition that the variables occurring in the quantifiers in the prefix shall be all different and shall all occur also in the matrix. (As special cases, the quantifiers constituting the prefix may be all universal, or they may be all existential, or the prefix may even be null so that B consists entirely of the quantifier-free matrix.)

Consistency.— A and $\sim A$ cannot both be theorems of a first-order functional calculus. The proof of this is by considering, for any well-formed formula of first-order functional calculus, a corresponding well-formed formula of the propositional calculus which is obtained as follows. From the given formula of first-order functional calculus, first delete (universal) quantifiers, so as to obtain a quantifier-free formula, then replace every propositional variable and every well-formed part of the form $f(x)$ or $f(x_1, x_2, \dots, x_n)$ —cf. the formation rules i_0, i_1, i_n —each by the propositional variable p . (For example, if the given formula is $(x)(y)F(x, y, z) \supset . p \supset q \supset (\exists z)G(z)$, the deletion of quantifiers yields $F(x, y, z) \supset . p \supset q \supset \sim \sim G(z)$, and hence the corresponding formula of the propositional calculus is $p \supset . p \supset p \supset \sim \sim p$.) As the reader may verify, every axiom of first-order functional calculus has the property that the corresponding formula of the propositional calculus is a tautology; moreover, the rules of inference preserve this property, i.e., if in an application of one of the rules of inference the premiss or premisses have this property, the conclusion must have it also; hence every theorem has this property. But A and $\sim A$ cannot both have this property (indeed, of the two corresponding formulas of the propositional calculus, the second one is obtained from the first by prefixing the sign \sim , so that not both can be tautologies). Hence not both A and $\sim A$ can be theorems.

The Metatheory of the Pure Functional Calculus of First Order contains many results of greater depth than the elementary fundamentals which have been discussed above. Only a few of these will be briefly indicated here.

A well-formed formula is said to be *satisfiable* in a particular non-empty domain if, when that domain is taken as the domain of individuals, the formula is satisfied by at least one system of values of its free variables which has individuals (of the domain in question) as values of the individual variables, n -ary propositional functions as values of the n -ary functional variables, and truth-values as values of the propositional variables. Similarly a well-formed formula is said to be *valid* in a particular non-empty domain if, when that domain is taken as the domain of individuals, the formula is satisfied by every such system of values of its free variables. A well-formed formula is said to be *satisfiable* if it is satisfiable in some non-empty domain, *valid* if it is valid in every non-empty domain. Evidently, A is satisfiable in a particular domain if and only if $\sim A$ is not valid in that domain, and A is satisfiable if and only if $\sim A$ is not valid.

The validity of a well-formed formula in a domain of individuals depends only on the number of individuals in the domain. And in fact well-formed formulas (*i.e.*, of the pure functional calculus of first order) can be classified as follows: there are those which are valid in no domain of individuals; for every positive integer n , there are those which are valid in domains of not more than n individuals but not valid in larger domains; there are well-formed formulas which are valid in every finite domain of individuals but not valid in an infinite domain; and there are the valid well-formed formulas. It can be shown that every well-formed formula belongs to one of these classes.—As examples we cite $(\exists x)(y) \cdot [F(x, y) \supset F(y, x)] \vee [F(x, x) \equiv F(y, y)]$, valid in domains of not more than three individuals, but not in larger domains, and $(\exists x)(y)(\exists z) \cdot F(x, x) \supset F(z, y) \supset F(x, y) \supset F(x, z)$, valid in all finite domains of individuals, but not in infinite domains.

The above statement includes the following theorem of Leopold Löwenheim: If a well-formed formula is valid in the domain of positive integers (*i.e.*, when the positive integers 1, 2, 3, ... are taken as the individuals), it is valid. As a corollary, or as another form of the metatheorem, if a well-formed formula is satisfiable, it is satisfiable in the domain of positive integers.

It can be shown that every theorem of the pure functional calculus of first order is valid (since the axioms are valid and the rules of inference preserve validity). The converse of this is the completeness (meta)theorem of Kurt Gödel: Every valid well-formed formula is a theorem.

A class of well-formed formulas (finite or infinite in number) is said to be *consistent* if it does not contain formulas A_1, A_2, \dots, A_n from which as hypotheses there is a valid inference to a conclusion B and also to $\sim B$. A class of well-formed formulas is said to be *simultaneously satisfiable* in a particular non-empty domain if, when that domain is taken as the domain of individuals, the formulas are simultaneously satisfied by at least one system of values of the free variables. And a class of well-formed formulas is said to be *simultaneously satisfiable* if it is simultaneously satisfiable in some non-empty domain.

According to an extension of Löwenheim's theorem by Thoralf Skolem, if a class of well-formed formulas is simultaneously satisfiable, it is simultaneously satisfiable in the domain of positive integers. And according to a closely related metatheorem due to Gödel, if a class of well-formed formulas is consistent, it is simultaneously satisfiable.

TRADITIONAL LOGIC

The name *traditional logic* is given to that part of the ancient and medieval logic which survived the decline of scholasticism and long remained with little change as a traditionally important part of philosophy. Though historically an independent doctrine, with a viewpoint and method that differ from the logistic method explained above, it can be exhibited as a part of modern logic, and this is the course which we shall follow here. In doing this it is necessary to make certain changes (as noted below), of which some remove uncertainties or correct confusions of the traditional doctrine, and others, though not required from the point of view of traditional logic itself, are desirable in order to incorporate it into the body of modern logic and to give it its proper place in relation to the remainder.

Categorical Propositions are propositions of the traditional subject-predicate form, having a subject S and a predicate P . The four forms—All S is P , No S is P , Some S is P , Some S is not P —are traditionally designated by the letters A, E, I, O respectively. Examples are: All men are mortal (A), All men die (A), No man can serve two masters (E), Some prime numbers are odd (I), A large island is in the bay (I), All that glitters is not gold (O). Propositions of the forms A and I are called *affirmative*; E and O , *negative*; A and E , *universal*; I and O , *particular*.

The subject and predicate of a categorical proposition are together called the *terms* of the proposition. Thus in the third example above, the terms are the subject, man, and the predicate, able to serve two masters.

In writing categorical propositions in logistic form we shall

use functional constants s and p to stand for the subject and predicate, so that the four forms appear as follows: $s(x) \supset p(x)$, $s(x) \supset \sim p(x)$, $s(x) \wedge p(x)$, $s(x) \wedge \sim p(x)$.

This manner of representing the categorical propositions is not faithful in all particulars to the traditional account. But among various possibilities it seems to be on the whole the best, and we shall employ it here, noting the four following points of divergence:

1. We have defined the notations \supset and \wedge in terms of the universal quantifier and the two primitive connectives \sim and \supset , whereas the traditional account might be thought to be more closely reproduced if \supset and \wedge were primitive notations.

2. The traditional account associates the negation in E and O with the *copula*, that is, with the words "is" or "is not" that join the subject and predicate, whereas here we prefix the sign \sim to the subformula $p(x)$.—In regard to 1 and 2 it would be possible to reproduce the traditional account more closely by using four primitive notations A_x, E_x, I_x, O_x , where $[s(x) A_x p(x)]$, $[s(x) E_x p(x)]$, $[s(x) I_x p(x)]$, $[s(x) O_x p(x)]$ are to have the meanings of $s(x) \supset p(x)$, $s(x) \supset \sim p(x)$, $s(x) \wedge p(x)$, $s(x) \wedge \sim p(x)$ respectively (and the usual quantifiers and sentence connectives could then be defined in terms of these). But it seems preferable not to complicate the formulation of first-order functional calculus in this way.

3. The traditional account includes also, under A and E , propositions expressed in the forms $p(a)$ and $\sim p(a)$ respectively, where a is an individual constant. For example, "Socrates is mortal" is considered as expressing an A proposition, and "Socrates is not mortal," an E proposition, the subject being the *singular term*, Socrates. These *singular propositions*, as they are called, will be ignored in our account of opposition and immediate inference, but will appear in connection with the categorical syllogism as giving special forms (called *singular forms*) of certain syllogisms.

4. Some aspects of the traditional account require that A and E be represented as we have here, others that they be represented by the conjunctions $(\exists x)s(x) \cdot s(x) \supset p(x)$ and $(\exists x)s(x) \cdot s(x) \supset \sim p(x)$ respectively. The problem of choosing between these two interpretations (or finding a satisfactory third alternative) is known as the problem of *existential import* of categorical propositions. In our account below we shall meet the difficulty by introducing $(\exists x)s(x)$ as a separate premiss at those places where it is required.

Opposition, Immediate Inference.—According to the *square of opposition*, if the subject and predicate are fixed, A and O (*i.e.*, $s(x) \supset p(x)$ and $s(x) \wedge \sim p(x)$) are *contradictory*, E and I are *contradictory*, A and E are *contrary*, I and O are *subcontrary*, A and I are *subaltern*, E and O are *subaltern*. The two propositions of a contradictory pair cannot be both true and cannot be both false. Under the premiss $(\exists x)s(x)$, the contrary pair, A, E , cannot be both true, the subcontrary pair, I, O , cannot be both false, and each of the propositions A and E has its subaltern proposition as a consequence.

Simple conversion of a categorical proposition consists in interchanging the subject and predicate. Thus the converses of $s(x) \supset p(x)$, $s(x) \supset \sim p(x)$, $s(x) \wedge p(x)$, and $s(x) \wedge \sim p(x)$ are respectively $p(x) \supset s(x)$, $p(x) \supset \sim s(x)$, $p(x) \wedge s(x)$, and $p(x) \wedge \sim s(x)$. Simple conversion is a generally valid inference only in the case of E and I .

Obversion of a categorical proposition is effected by replacing p by a functional constant q which denotes the negation of the propositional function (the complement of the class) that is denoted by p , and at the same time inserting \sim if not already present or deleting it if present. In terms of the abstraction operator, the functional constant q is $\lambda x \sim p(x)$. Thus the obverse of $s(x) \supset p(x)$ is $s(x) \supset \sim q(x)$ (the obverse of *All men are mortal* is *No men are immortal*). Similarly, the obverse of $s(x) \supset \sim p(x)$ is $s(x) \supset q(x)$, the obverse of $s(x) \wedge p(x)$ is $s(x) \wedge \sim q(x)$, and that of $s(x) \wedge \sim p(x)$ is $s(x) \wedge q(x)$.

The name "immediate inference" is given to certain inferences from one categorical proposition as premiss to another as conclusion, all of them being valid inferences either of first-order functional calculus or of an extended calculus embracing the

abstraction operator λ . The immediate inferences include obversion of A, E, I, O , simple conversion of E, I , and subalternation of A, E —of which subalternation requires the additional premiss $(\exists x)s(x)$. Other immediate inferences may be obtained by means of sequences of these; e.g., given that all men are mortal we may take the obverse of the converse of the obverse and so infer that all immortals are non-men (called by some the contrapositive, by others the obverted contrapositive).

Conversion *per accidens*, or *by limitation*, of a proposition A may be described as consisting of subalternation followed by simple conversion. Thus from the premisses $s(x) \supset_p p(x)$ and $(\exists x)s(x)$ it yields the conclusion $p(x) \wedge_x s(x)$. Conversion *per accidens* of E is also possible, by a simple conversion followed by subalternation.

Categorical Syllogism.—The name "categorical syllogism" is given to certain valid inferences of first-order functional calculus which involve as premisses two categorical propositions having a term in common—the *middle term*. Using functional constants s, m, p to stand for the *minor term*, the *middle term*, and the *major term* respectively, we give the traditional classification into figures and moods. In each case we give the *major premiss* first, the *minor premiss* immediately after it, and the conclusion last; in some cases we give a third (existential) premiss which is suppressed in the traditional account. Where in consequence of the admission of singular propositions (as noted above) two different forms of valid inference appear under the same figure and mood, we give the singular forms in a separate list.

First Figure

Barbara: $m(x) \supset_p p(x), s(x) \supset_p m(x); s(x) \supset_p p(x)$.
 Celarent: $m(x) \supset_p \sim p(x), s(x) \supset_p m(x); s(x) \supset_p \sim p(x)$.
 Darii: $m(x) \supset_p p(x), s(x) \wedge_x m(x); s(x) \wedge_x p(x)$.
 Ferio: $m(x) \supset_p \sim p(x), s(x) \wedge_x m(x); s(x) \wedge_x \sim p(x)$.

Second Figure

Cesare: $p(x) \supset_p \sim m(x), s(x) \supset_p m(x); s(x) \supset_p \sim p(x)$.
 Camestres: $p(x) \supset_p m(x), s(x) \supset_p \sim m(x); s(x) \supset_p \sim p(x)$.
 Festino: $p(x) \supset_p \sim m(x), s(x) \wedge_x m(x); s(x) \wedge_x \sim p(x)$.
 Baroco: $p(x) \supset_p m(x), s(x) \wedge_x \sim m(x); s(x) \wedge_x \sim p(x)$.

Third Figure

Darapti: $m(x) \supset_p p(x), m(x) \supset_p s(x), (\exists x)m(x); s(x) \wedge_x p(x)$.
 Disamis: $m(x) \wedge_x p(x), m(x) \supset_p s(x); s(x) \wedge_x p(x)$.
 Datisi: $m(x) \supset_p p(x), m(x) \wedge_x s(x); s(x) \wedge_x p(x)$.
 Felapton: $m(x) \supset_p \sim p(x), m(x) \supset_p s(x), (\exists x)m(x); s(x) \wedge_x \sim p(x)$.
 Bocardo: $m(x) \wedge_x \sim p(x), m(x) \supset_p s(x); s(x) \wedge_x \sim p(x)$.
 Feriso (or Ferison): $m(x) \supset_p \sim p(x), m(x) \wedge_x s(x); s(x) \wedge_x \sim p(x)$.

Fourth Figure

Bamalip (or Bramantip): $p(x) \supset_p m(x), m(x) \supset_p s(x), (\exists x)p(x); s(x) \wedge_x p(x)$.
 Calemes (or Camenes): $p(x) \supset_p m(x), m(x) \supset_p \sim s(x); s(x) \supset_p \sim p(x)$.
 Dimatis (or Dimaris): $p(x) \wedge_x m(x), m(x) \supset_p s(x); s(x) \wedge_x p(x)$.
 Fesapo: $p(x) \supset_p \sim m(x), m(x) \supset_p s(x), (\exists x)m(x); s(x) \wedge_x \sim p(x)$.
 Fresison: $p(x) \supset_p \sim m(x), m(x) \wedge_x s(x); s(x) \wedge_x \sim p(x)$.

Singular Forms

Barbara: $m(x) \supset_p p(x), m(a); p(a)$.
 Celarent: $m(x) \supset_p \sim p(x), m(a); \sim p(a)$.
 Cesare: $p(x) \supset_p \sim m(x), m(a); \sim p(a)$.
 Camestres: $p(x) \supset_p m(x), m(a); p(a)$.
 Darapti: $p(a), s(a); s(x) \wedge_x p(x)$.
 Felapton: $\sim p(a), s(a); s(x) \wedge_x \sim p(x)$.

The last two singular forms, in which the middle term is singular, are classed separately as the *expository* syllogism.

Some add the five so-called weakened moods, Barbari, Celarent, Cesaro, Camestros, Calemos, to be obtained by subalternation of the conclusion from Barbara, Celarent, Cesare, Camestres, Calemes respectively. The five moods of the fourth figure are sometimes classed instead as indirect moods of the first figure, the major and minor premisses being interchanged, and the names being then given as Baralipon, Celantes, Dabitis, Fapesmo, Frisesomorum.

The names of the moods have a mnemonic significance, in which the first three vowels indicate whether the major premiss, minor premiss, and conclusion, in order, are A, E, I , or O , and some of the consonants indicate the traditional reductions of the other moods to the four direct moods of the first figure (see LOGIC, HISTORY OF).

Hypothetical Syllogism, Disjunctive Syllogism, Dilemma.—Besides the categorical syllogism, the traditional logic treats also a number of other kinds of *mediate* inference (i.e., inference from two or more premisses), including especially the *hypothetical syllogism* (or conditional syllogism), the *disjunctive syllogism*, and the *dilemma*. All of these can be exhibited as valid inferences of the propositional calculus, and we shall give them here in this form.

In particular, we shall render the words "if" or "if... then," as used in stating the traditional hypothetical (or conditional) propositions, by the sign \supset of material implication, although this is certainly contrary to the intention of traditional writers. In the Port-Royal Logic, for example, the contradictory negative of *If you eat of the forbidden fruit you will die* is given as *Although you eat of the forbidden fruit you will not die*—whereas if material implication were intended, the contradictory should be rather, *You will eat of the forbidden fruit and you will not die*. Yet in the same work it is explained that a conditional proposition may be true although both parts of it (both the antecedent and the consequent) are false, provided only that the consequence is correctly drawn.

By this it is not meant that the consequent must follow logically from the antecedent, but, as is clear from the discussion and the examples given, that the consequent must follow from the antecedent together with known truths which are taken into consideration. However, this account overlooks that, if two propositions are both false, it is always possible to infer one from the other by means of appropriately chosen truths, which may then be supposed to be known and taken into consideration. It is in this way that the traditional account leads to material implication as the best means of representing it consistently within a more complete theory. An alternative amendment of the traditional account indeed suggests itself, by seeking a satisfactory logistic theory of an implication connective which shall reproduce more closely the ordinary usage of "if... then" in future conditions and conditions contrary to fact, but this has never been successfully carried out. (Compare the discussion of material implication in the first part of this article.)

There is also a question whether the word "or," as used in stating the traditional disjunctive propositions, shall be understood as denoting inclusive disjunction or exclusive disjunction. Here the traditional logic is more explicitly inconsistent—since, although most of the inferences are valid inferences under either interpretation of the word "or," one of them, the *modus ponendo tollens*, is valid only for exclusive disjunction, and the two complex dilemmas are valid only for inclusive disjunction. We shall use exclusive disjunction in *modus ponendo tollens*, but inclusive disjunction elsewhere.

In each entry in the following table the major premiss is given first, or the two major premisses in the case of the dilemmas, then the minor premiss, then the conclusion.

Hypothetical Syllogism

Modus ponens: $A \supset B, A; B$.

Modus tollens: $A \supset B, \sim B; \sim A$.

Disjunctive Syllogism

Modus tollendo ponens: $A \vee B, \sim A; B$.

Modus tollendo ponens: $A \vee B, \sim B; A$.

Modus ponendo tollens: $A \neq B, A; \sim B$.

Modus ponendo tollens: $A \neq B, B; \sim A$.

Dilemma

Simple constructive dilemma: $A \supset C, B \supset C, A \vee B; C$.

Simple destructive dilemma: $A \supset B, A \supset C, \sim B \vee \sim C; \sim A$.

Complex constructive dilemma: $A \supset B, C \supset D, A \vee C; B \vee D$.

Complex destructive dilemma: $A \supset B, C \supset D, \sim B \vee \sim D; \sim A \vee \sim C$.

The inferences from $A \supset B$ and $C \supset A$ to $C \supset B$, and from $A \supset B$ and $C \supset \sim B$ to $C \supset \sim A$ are sometimes added as *pure hypothetical* syllogisms, and the above simpler forms of the hypothetical syllogism are then distinguished as *mixed hypothetical*. Some older works, including the Port-Royal Logic, add a *copulative* syllogism, with major premiss $\sim \cdot AB$, minor premiss A and conclusion $\sim B$, or minor premiss B and conclusion $\sim A$.

TYPE THEORY AND SET THEORY

In the functional calculus of first order there is provision only for individuals as arguments of propositional functions, and it is only individual variables which may be bound by quantifiers. Since the domain of individuals is fixed in advance, and since the classes and relations (and propositional functions generally) which are values of the functional variables are not among the individuals of the fixed domain, this imposes a limitation upon what can be expressed in the notation of the calculus. Indeed it may be thought that the propositions of logic have a character of universal generality which demands for its expression the use of variables of unrestricted range, whose values are not confined to a fixed domain but may be either individuals or classes or relations or anything else whatever. And just this was maintained in particular by Gottlob Frege.

However, the uncritical attempt to introduce such variables of unrestricted range leads to a system which is inconsistent, if besides the variables of unrestricted range, say x, y, z, x_1, \dots , we employ also the usual sentence connectives and quantifiers, and a notation, say $\epsilon(x, y_1, \dots, y_n)$, to mean that x is an n -ary propositional function and holds among the arguments y_1, y_2, \dots, y_n , and adopt what seem to be the natural and obvious axioms and rules of inference. Namely in such a system the antinomy of Bertrand Russell or that of C. Burali-Forti (see ANTINOMY) can be reproduced formally, i.e., in the form of proofs of contradictory theorems of the system. And in fact the significance of these antinomies lies less in their informal statement in words than in their influence upon the construction of logistic systems, through the possibility of their logistic formalization.

In order to obtain a system more comprehensive than functional calculus of first order without falling into antinomy, there are two directions which have been followed. One of these, the direction of type theory, avoids altogether the use of variables of unrestricted range, and introduces instead many different kinds of variables with different restricted ranges. The other, the direction of set theory, has variables of unrestricted range, but imposes restrictions in regard to the existence of sets determined by given conditions. (The word "set" is here used to mean a class which can belong to another class as a member of it, since some forms of set theory admit also classes which are not sets; but outside the context of set theory the words "class" and "set" are generally used synonymously.)

As typical of the two directions we shall describe briefly the simple theory of types, and a form of set theory which is based on the system proposed by Ernst Zermelo in 1908.

The Simple Theory of Types can be described as obtained from the pure functional calculus of first order by successive additions to it.

The first step is to modify the formation rule iv to provide that $(x)A$ shall be well-formed when x is a propositional or functional variable as well as when x is an individual variable. The resulting system is the *pure functional calculus of second order*, if suitable axioms and rules of inference are provided (which will not be stated here, but are similar to those for functional calculus of first order).

Then functional variables of various higher types are adjoined. Namely if c_1, c_2, \dots, c_n are non-negative integers, then (c_1, c_2, \dots, c_n) is a type, and an infinite list of variables of this type is provided: $F^{(c_1, c_2, \dots, c_n)}, G^{(c_1, c_2, \dots, c_n)}, \dots$. A formation rule provides that, if f is of type (c_1, c_2, \dots, c_n) , then $f(x_1, x_2, \dots, x_n)$ is well-formed on condition that each variable x_i is of the type indicated by the corresponding integer c_i , i.e., that x_i is an individual variable if c_i is 0, x_i is a propositional variable if c_i is 1, and x_i is an m -ary functional variable of lower type (one of the variables $F^m, G^m, H^m, F_1^m, \dots$) if c_i is $m+1$. The values of the variables of type (c_1, c_2, \dots, c_n) are propositional functions of the kind which is indicated by this formation rule. And the resulting system, if the new variables of higher types occur only as free variables, and if again suitable axioms and rules of inference are provided, is the *pure functional calculus of third order*. Upon further modifying the formation rule iv, to

allow the new variables of higher types to occur also as bound variables, the *pure functional calculus of fourth order* is obtained.

Then the next step is to adjoin functional variables of still higher types; e.g., one of these new types is $(0, (2, 3), (3))$, and if f is a variable of this type, then $f(x_1, x_2, x_3)$ is well-formed on condition that x_1 is an individual variable, x_2 is a variable of type $(2, 3)$, and x_3 is a variable of type (3) .

In this way, by successive adjunctions of functional variables of higher and higher types—with appropriate changes, at each stage, in the formation rules, axioms, and rules of inference—the pure functional calculi of all finite orders are obtained. The logistic system which embraces all of these in a single system is the *pure functional calculus of order ω* .

A notation $=$, to express that two things are the same or identical, may be introduced by definition:

$$x = y \rightarrow (F^e) \cdot F^e(x) \supset F^e(y),$$

where x and y are variables of the same type, and where the particular letter F is used, with type superscript e so chosen as to make $F^e(x)$ and $F^e(y)$ well-formed.

Finally, to the axioms of the pure functional calculus of order ω , there are added one special axiom, the *axiom of infinity*, and two special axiom schemata, which provide the *axioms of extensionality* and the *axioms of choice*.

The axiom of infinity is to the effect that the number of individuals is infinite. There are many ways in which an axiom having this as a consequence may be formulated in the notation of the system, of which the following (based on an idea of Kurt Schuette) is perhaps the briefest:

$$(\exists F)(x)(\exists y)(s) \cdot \sim F(x, x) \cdot F(x, y) \cdot F(y, x) \supset F(z, y)$$

The axioms of extensionality are that two n -ary propositional functions are identical if they hold among exactly the same ordered sets of n arguments:

$$f(x, y, \dots, u) =_{xy \dots u} g(x, y, \dots, u) \supset f = g,$$

where x, y, \dots, u is any ordered set of n different variables (which may be of various types, the same or different, n being any positive integer), and where f and g are variables of such type as to make $f(x, y, \dots, u)$ and $g(x, y, \dots, u)$ well-formed.

The axioms of choice, or *multiplicative axioms* as they are also called, are:

$$c(f)c(g) \supset_{fg} [f(x)g(x) \supset x \cdot f = g] \supset (\exists h) \cdot c(f) \supset_{f \cdot f(z)} f(z) \supset_{z \cdot (\exists y) \cdot f(x)h(x)} x \cdot x = y,$$

where c, f, g, h, x, y, z are variables which must be no two the same, and of such types that the formula is well-formed.

For the simple theory of types without axiom of infinity a proof of consistency is possible which is similar to that given above for the functional calculus of first order, and which, although more complicated, employs only methods of essentially the same elementary character.

On the other hand it is a consequence of Goedel's incompleteness theorem (see the explanation below) that any proof of consistency of the system with axiom of infinity cannot be of such elementary character, but must employ methods of proof that in some sense surpass anything available in the simple theory of types itself.

The Set Theory of Zermelo can be described as obtained by adjoining additional axioms to a simple applied functional calculus of first order which has one binary functional constant ϵ and one individual constant Λ . The constant ϵ denotes the relation of membership in a set, so that $\epsilon(x, y)$ may be read as " x belongs to the set y " or " y is a set and x is a member of y ." The constant Λ denotes the empty set (the set which has no members). The individual variables may in this theory be regarded as variables of unrestricted range, in the sense that the theory assumes the existence of no entities (sets or others) that cannot be values of the individual variables.

In writing well-formed formulas we shall abbreviate $\epsilon(x, y)$ as xy ; i.e., to state it as a definition: $xy \rightarrow \epsilon(x, y)$.

The notation $=$ may be introduced by a definition analogous to that given above in connection with the simple theory of types: $x = y \rightarrow xez \supset yez$. A notation \subset , to express that one set is a part of (a subset of) another, may be introduced by a similar definition: $x \subset y \rightarrow xez \supset yez$. In both cases z is to be chosen

as the first individual variable (in alphabetic order) which is different from both x and y .

To provide for the notion of an ordered pair, a notation $\{x, y, z\}$ may be introduced to express that z is the ordered pair of x and y : $\{x, y, z\} \rightarrow uex \equiv u \cdot [veu \equiv v \cdot v = x] \vee v \cdot veu \equiv v \cdot v = x \vee v = y$, where u and v are to be chosen as the first two individual variables different from x, y , and z . Relations may then be dealt with in the theory by understanding a relation to be a set of ordered pairs.

The axioms of the theory are those of the functional calculus of first order, and in addition the following axioms and axiom schemata:

Axiom of extensionality: $zex \supset \cdot zex \equiv \cdot zey \supset x = y$.

Axiom of the empty set: $\sim x \in \Lambda$.

Axiom of pairing: $(\exists t) \cdot zel \equiv \cdot z = x \vee z = y$.

Axiom of summation of sets: $(\exists t) \cdot zel \equiv \cdot (\exists y) \cdot zey \cdot yex$.

Axiom of the set of subsets: $(\exists t) \cdot zel \equiv \cdot z \subset x$.

Axioms of subset formation: $(\exists t) \cdot zel \equiv \cdot zex \cdot Az$, where Az is a well-formed formula which may have z as a free variable but does not have t as a free variable.

Axiom of choice: $yex \cdot zex \supset_{yz} [uey \cdot uez \supset u \cdot y = z] \supset (\exists t) \cdot yex \supset_{yz} \cdot wey \supset_{yz} (\exists v) \cdot uey \cdot uel \equiv u \cdot u = v$.

Axiom of infinity: $(\exists t) \cdot \Delta el \cdot xel \supset (\exists y) \cdot yel \cdot zey \equiv \cdot zex \vee z = x$.

Axioms of replacement: $yex \supset_y (\exists u) [Ayz \equiv \cdot z = u] \supset (\exists t) \cdot zel \equiv \cdot (\exists y) \cdot yex \cdot Ayz$, where Ayz is a well-formed formula which may have y and z as free variables but does not have t or u as a free variable.

Axioms of excluded infinite regress: $(\exists x)Ax \supset (\exists x) \cdot Ax \cdot yex \supset_y \sim Ay$, where Ax is a well-formed formula which may have x as a free variable but does not have y as a free variable.

The way in which the theory seeks to avoid antinomy may be seen in particular in connection with the axioms of subset formation. An uncritical formulation might well have included the stronger axiom schema $(\exists t) \cdot zel \equiv \cdot Az$, providing for the existence of a set t of those things z (sets and others) which satisfy an arbitrary given condition Az . But this axiom schema would lead directly to the Russell antinomy, upon taking Az to be $\sim zex$. The weaker schema actually used (the axioms of subset formation) provides only for the existence of a set t of those things z which belong to a previously given set x and satisfy the condition Az . This is not known to lead to antinomy; but $\sim(\exists t) \cdot zel \equiv \cdot \sim zex$ is a theorem.

Concerning the history of these axioms for set theory, see the paragraph about Zermelo in the article LOGIC, HISTORY OF. The axioms of replacement and of excluded infinite regress are additions to the original axiom system of Zermelo, and are sometimes omitted, as although they are independent and for some purposes important, there are also many purposes for which they are not needed.

On the other hand, if the axioms of replacement are retained in the form in which we have here stated them, they have the effect of rendering the axioms of subset formation non-independent; i.e., the axioms of subset formation may then be omitted from the list on the ground that they can be proved as theorems by using the axioms of replacement.

An extension of the Zermelo set theory which is due to John von Neumann and Paul Bernays (see the paper of Bernays cited in the bibliography) adds, to the sets of the Zermelo theory, also classes which are not sets, i.e., which cannot be members of other classes or sets. And for every condition Ax expressed in the notation of the Zermelo theory there is a class of those elements x which satisfy Ax —where an *element* is a set or anything capable of being a member of a set. (In particular there is, according to this extended theory, a class of elements x such that $\sim zex$, but not a set of such elements.)

Two other, different, systems of set theory are treated by W. V. Quine, one in his paper cited in the bibliography, and the other in the 1951 edition of his book. The latter, due jointly to Quine and Hao Wang, is related to Quine's system of 1937. These are not forms of the Zermelo theory but seek to exclude the antinomies by different means.

Goedel's Incompleteness Theorem.—In contrast with the completeness theorem for the pure functional calculus of first order, all known systems of type theory or set theory which are of sufficient strength to provide a logical foundation of mathematics are incomplete. We state this incompleteness theorem, due to Goedel, in the slightly stronger form which was given to it by Barkley Rosser. On the hypothesis that the system in question—it may be in particular either the simple theory of types or any of the systems of set theory mentioned above—is consistent, there is a well-formed formula A which is a sentence (hence without free variables) such that neither A nor $\sim A$ is a theorem.

The proof of the metatheorem proceeds by constructing a particular well-formed formula A , and then showing that, if the system is consistent, A cannot be a theorem, and $\sim A$ cannot be a theorem. However, it can also be shown that, if the system is consistent, the proposition expressed by A is true. More accurately, we can show, by means that are formalizable in the system itself, "If the system is consistent, then _____," filling the blank with a statement of the proposition that is expressed by A . Hence the further metatheorem follows that the consistency of the system cannot be proved by means that are formalizable in the system itself. (This brief statement of the matter is incomplete, and some essential explanations which are here omitted will be found in the article MATHEMATICS, FOUNDATIONS OF.)

Both the incompleteness theorem and the further theorem about the possibility of a consistency proof have the striking feature that they hold not only for a particular system but for any arbitrary extension of it that may be obtained by adjoining additional axioms or rules of inference or both, provided only that the requirement is satisfied that the axioms and rules of inference shall be effective (as described in the first part of this article, in explaining the notion of a logistic system). Having a particular system, which we suppose consistent, and having constructed the sentence A which is then true but not a theorem, we may indeed strengthen the system by adding A to it as an axiom. But the resulting stronger system is still incomplete: in it a particular sentence B may again be constructed by the same method, and it may be shown on the hypothesis of consistency that neither B nor $\sim B$ is a theorem, and that the proposition expressed by B is true.

LOGIC, HISTORY OF. In this article the history of logic is presented as follows:

- I. Ancient Logic
 1. Aristotle
 2. Theophrastus
 3. Stoics and Megarians
 4. The Last Period
- II. Logic in India
 1. Origins
 2. The Old Nyaya (Pracina-nyaya)
 3. The New Nyaya (Navya-nyaya)
- III. Scholastic Logic
 1. Period of the "Old Logic" (Ars Vetus)
 2. Period of the "New Logic" (Ars Nova)
 3. Rise of Terministic Logic
 4. Classical Period of Scholastic Logic
 5. Decline of Scholastic Logic

IV. Modern Logic

1. Ramée
2. Jungius
3. Geulincx
4. Port-Royal Logic
5. Saccheri
6. Leibniz
7. Euler
8. Kant
9. Hegel
10. Bolzano
11. Mill
12. Algebra of Logic
13. Peirce
14. Brentano
15. Frege
16. Venn
17. Peano
18. Burali-Forti
19. Russell
20. Zermelo
21. Richard
22. Hilbert
23. Brouwer
24. Lewis
25. Loewenheim
26. Skolem
27. Post
28. Lukasiewicz
29. Tarski
30. Carnap
31. Herbrand
32. Goedel

I. ANCIENT LOGIC

1. **Aristotle.**—The history of ancient logic begins with Aristotle. This is not to say that until Aristotle's time no one was capable of reasoning correctly. The works of Plato are full of interesting arguments, valid and invalid, and, indeed, the same may be said for nearly all of ancient literature—whether written by philosophers, mathematicians, scientists, historians, grammarians or even by poets—both before and after the discovery of the syllogism. However, in determining the scope of a history of logic, one should not fail to distinguish sharply between the use of logical principles, which may be attributed to anyone who reasons, and the *mention and study* of such principles. Only the latter is specifically the business of logic and accordingly is relevant to its history. It is true that the logician himself, like any other theorist, will have to construct arguments and proofs concerning his subject matter. Nevertheless, it is important even in his case to distinguish between the principles he mentions and those he uses. Thus, for instance, when Aristotle proves his various assertions about the syllogism he often argues in accord with inference patterns which are clearly not syllogistic and which, since he never discusses them explicitly, cannot be considered a part of his logic.

Most of Aristotle's contributions to logic are found in a group of treatises known in later times under the title *Organon* and consisting of the *Categories*, *De Interpretatione*, the *Analytics*, the *Topics*, and the *Sophistical Refutations*. These treatises also contain much that lies outside the field of logic. All of them are written in the abbreviated, notebook style which is typical of the entire Aristotelian corpus, and they abound in textual difficulties. The authenticity of the first two is open to doubt, and the order in which the various works were written is unknown. Yet despite such problems and obscurities one cannot fail to be impressed by the sure and masterful way in which Aristotle sets forth his remarkable discoveries in logic. Most of the relevant material is found in the *Prior Analytics* and the *De Interpretatione* (*Perihermenias*), and we shall therefore restrict ourselves to a quite summary treatment of the remaining portions of the *Organon*.

The *Categories* begins with a division of linguistic expressions into simple and composite. Examples of the composite are "A man runs," "A man wins"; of the simple, "man," "ox," "runs," and "wins." Aristotle then states that every simple expression means one of the following: substance, quantity, quality, relation, place, time, position, state, action, affection; and he devotes the remainder of the treatise to a discussion of these categories. Most of what is included is not directly relevant to the history of logic,

but there are a few passages which bear upon the question of interpreting the important idiom "is predicated of," in terms of which syllogisms are typically stated by Aristotle. Unfortunately, the evidence afforded by these passages tends only to confirm what we gather from the *Analytics*, namely, that Aristotle was not fully clear whether he was speaking of a relation between a thing and a word, or between two things, or between two words. The difficulty is well illustrated by his statement of the one logical principle mentioned in the *Categories*:

Whenever one thing is predicated of another as of a subject, everything said of what is predicated will also be said of the subject; for example, man is predicated of some particular man, and animal of man; thus animal will be predicated of the particular man also.

The *De Interpretatione* continues the classification of linguistic expressions and sets forth some elementary logical relations among declarative sentences of the simplest types. Sentences, as well as the nouns and verbs of which they are composed, are defined as certain species of significant sounds. Observing that some of them, e.g., prayers, are neither true nor false, Aristotle dismisses these as "belonging to the study of rhetoric or poetry" and restricts the discussion to declarative sentences. These are divided into simple and composite: the simple either affirms or denies something of something, while the composite results from conjoining simples. Further restricting the subject to simple sentences, Aristotle divides them into eight groups, explaining as follows: Some things are universal, he says, and some are particular. By "universal" he means what is of such a nature as to be predicated of many things; by "particular," what is not of such a nature; thus Man is a universal, and Callias is a particular. Now some of our (simple declarative) sentences concern a universal as subject, and others concern a particular. For example, the positive and negative sentences "Socrates is white," "Socrates is not white" both concern a particular, viz., Socrates. Of those which have a universal subject, several kinds are distinguished. Such sentences as "Every man is white" and "No man is white," later known respectively as *A-* and *E-propositions*, are said to be of a universal character and about a universal subject. The words "every" and "no" are the marks of the universal character, and in these examples Man is the universal subject. There are two kinds of sentences which are not of a universal character but are nevertheless about a universal subject. First we have such sentences as "Some man is white" and "Not every man is white," later called *I-* and *O-propositions*, and described in the *Prior Analytics* as "particular" sentences. In addition there are sentences like "Man is white" and "Man is not white," called "indefinite" in the *Prior Analytics*.

An affirmation and a denial which have the same subject and predicate, but one of which is of a universal character while the other is not, are called "contradictories" by Aristotle. Thus, "Every man is white" and "Not every man is white" are contradictories, as are "No man is white" and "Some man is white." Of a pair of contradictories, exactly one must be true. An affirmation and denial which have the same subject and predicate and each of which is of a universal character are called "contraries." It is not possible for both members of a pair of contraries to be true, but it can happen that both of their contradictories are true. In other words, contraries may be simultaneously false. This is the case, for example, with the contraries "Every man is white" and "No man is white." In the centuries after Aristotle these relationships were presented schematically by means of the well-known Square of Opposition, which first appears in Apuleius' commentary on *De Interpretatione*.

The remainder of the treatise consists of an unsystematized miscellany of observations, some interesting, some obscure and confused. There is a discussion purporting to show that if one member of every pair of contradictory sentences is true and the other is false, then everything happens by necessity and nothing by chance. The argument is unclear, but it appears to rest in part upon a confusion between true sentences like "Necessarily, if 'Snow is white' is true, then snow is white" and their more idiomatic (as also in Greek) but strictly false counterparts, "If 'Snow is white' is true, then necessarily snow is white." On another subject, Aristotle makes the interesting point that the word "is" has a

different sense in "Homer is" from what it has in "Homer is a poet," and that the former of these sentences does not follow from the latter. In still another place he notices that some predicates will combine in a way in which others will not: thus, from "Socrates is two-footed" and "Socrates is a man" we can deduce correctly "Socrates is a two-footed man"; whereas from "He is good" and "He is a shoemaker" it would be incorrect to infer "He is a good shoemaker." This is reminiscent of the Platonic example: "He (a dog) is yours and he is a father. Therefore, he is your father." The core of Aristotle's logic is in the first seven chapters of Book I of the *Prior Analytics*. There, within the space of a very few pages, is set forth the theory of the syllogism, an intellectual discovery that was of unequalled magnitude for its time and which dominated the science of logic for 2,000 years.

Aristotle first describes the kinds of sentences which may be components of syllogisms. The classification is somewhat different from that given in *De Interpretatione*. Every premiss and conclusion, he says, affirms or denies something of something and thus is positive or negative. It will also be universal, particular, or indefinite. A universal sentence asserts that something belongs to all or none of something else; a particular sentence asserts that something belongs to some or not to some or not to all of something else; an indefinite sentence merely asserts, neither in general nor in particular, that something belongs or does not belong to something else, e.g., that pleasure is not good. Strictly speaking, the foregoing is an account only of assertoric premisses; there are also problematic premisses, to the effect that something *may* belong to something else; and apodictic premisses, which state that something *must* belong to something else. These also are divided into six kinds, in the same way in which the assertoric premisses are so divided. It will be noticed that no mention is made of sentences with particular subjects (in later terminology, singular sentences, or singular propositions). They are entirely ignored in the *Prior Analytics*, and consequently the ancient and familiar example of a syllogism:

All men are mortal.
Socrates is a man.
Therefore, Socrates is mortal.

is quite un-Aristotelian. Furthermore, the indefinite sentences, too, are very nearly ignored by Aristotle. According to Alexander, the reason is that they are "equivalent" to particular sentences.

In preparation for his deductive exposition of the syllogistic Aristotle states the laws of conversion. The universal negative sentence converts into a universal negative; e.g., if no pleasure is good, then no good will be pleasure. The universal and particular affirmative sentences convert, but into particular affirmatives; e.g., if every pleasure is good, then some good is pleasure, and if some pleasure is good, then again some good is pleasure. The particular negative does not convert, since, for example, it does not follow that if some animal is not a man, then some man is not an animal. Using variables Aristotle states these laws in a general way and demonstrates them by procedures known as *ekthesis* and *reductio ad impossibile*:

First, then, let the premiss AB be a universal negative. If A belongs to no B , then B will not belong to any A . For if it belonged to some A —for instance, to C —then it would not be true that A belonged to no B , for C is one of the B 's. And if A belongs to all B , then B will belong to some A . For if it belonged to no A , A would belong to no B , whereas it was assumed to belong to all B . And likewise if the premiss is particular. For if A belongs to some B , then necessarily B belongs to some A , since if it belonged to none, A would belong to no B . On the other hand, if A does not belong to some B , it is not necessary that B should not belong to some A ; for example, let B be Animal and A be Man. For Man does not belong to every Animal, but Animal does belong to every Man.

The Aristotelian definition of "syllogism" is as follows: a syllogism is discourse in which, certain things being posited, something else follows necessarily from their being so. However, his definition is far too wide, applying to nearly all valid arguments, and it does not agree with his own practice. A much better idea of what is meant by "syllogism" may be derived from an examination of the syllogistic formulas actually set forth. The following literal translations will serve this purpose and will illustrate the methods of reduction. Important words which do not occur in

Aristotle's abbreviated statements but which seem to be required by the sense and syntax are enclosed within parentheses. The scholastic names for the moods are due to Peter of Spain.

Barbara. For if A (is predicated) of all B and B of all C , it is necessary for A to be predicated of all C . (*An. Pr.* I, 25 b 37)

Celarent. Likewise, if A (is predicated) of no B but B of all C , (it is necessary) that A will belong to no C . (25 b 40)

Darii. Let A belong to all B , and B to some C . Then if "predicated of all" means what was said at the beginning, it is necessary for A to belong to some C . (26 a 23)

Ferio. And if A belongs to no B , but B to some C , it is necessary that A does not belong to some C . (26 a 25)

Cesare. Let M be predicated of no N but of all O . Then, since the negative converts, N will belong to no M . But M was assumed (to belong) to all O ; so that N (will belong) to no O ; for this has been shown previously. (27 a 5)

Camestres. Again, if M (belongs) to all N but to no O , neither will N belong to any O . For if M (belongs) to no O , then O (belongs) to no M ; but M belonged to all N ; therefore, O will belong to no N ; for the first figure has been produced again. And since the negative converts, N will belong to no O . (27 a 9)

Festino. For if M belongs to no N but to some O , it is necessary for N not to belong to some O . For since the negative converts, N will belong to no M . But M was assumed to belong to some O , so that N will not belong to some O ; for a syllogism in the first figure is obtained. (27 a 32)

Baroco. Again, if M belongs to all N but not to some O , it is necessary for N not to belong to some O . For if it belongs to all, and M is also predicated of all N , it is necessary for M to belong to all O . But it was assumed not to belong to some. (27 a 36)

Darapti. Whenever both P and R belong to all S , (it is true) that P will of necessity belong to some R . For since the affirmative converts, S will belong to some R , so that since P (belongs) to all S , and S to some R , it is necessary for P to belong to some R . For a syllogism in the first figure is produced. It is also possible to make the proof *per impossibile* and by *ekthesis*. For if both belong to all S , then if one of the S 's, e.g., N , is taken, both P and R will belong to this, so that P will belong to some R . (28 a 17)

Felapton. And if R belongs to all S , but P to none, there will be a syllogism that of necessity P will not belong to some R . The same type of proof (will work) by converting the RS premiss. It might also be shown *per impossibile*, as in the previous cases. (28 a 26)

Disamis. For if R (belongs) to all S and P to some, it is necessary for P to belong to some R . For since the affirmative converts, S will belong to some P , so that since R (belongs) to all S , and S to some P , R will belong to some P . So that P (will belong) to some R . (28 b 7)

Datisi. Again, if R belongs to some S and P to all, it is necessary for P to belong to some R . For the same method of demonstration (will work). And it is also possible to demonstrate it both *per impossibile* and by *ekthesis*, just as in the previous cases. (28 b 11)

Bocardo. For if R (belongs) to all S and P does not belong to some, it is necessary for P not to belong to some R . For if to all, and R (belongs) to all S , P will also belong to all S . But it did not so belong. It is also proved without reduction, if one of the S 's to which P does not belong is taken. (28 b 17)

Ferison. For if P (belongs) to no S , but R belongs to some S , P will not belong to some R . For the first figure will be produced again when the RS premiss is converted. (28 b 33)

Pesapo and Fresison. premisses in reversed order. . . . such as, if A (belongs) to all B or to some, but B to no C . For when the premisses are converted it is necessary for C not to belong to some A . Likewise in the other figures: a syllogism always results from conversion of the premisses. (29 a 23)

There is some question as to how these formulas should be interpreted. Traditionally, "Aristotelian" syllogisms have been presented as arguments and not as conditional sentences. The well-known example of a syllogism in Barbara has the form of an argument consisting of two premisses and a conclusion:

All men are mortal.
All Greeks are men.
Therefore, all Greeks are mortal.

As J. Lukasiewicz emphasized, this cannot be obtained by substituting terms for variables in the Aristotelian formula. The difficulty is not only that Aristotle uses expressions like " A is predicated of all B " or " A belongs to all B " instead of " $All B$ is A "; more important, nearly all of the Aristotelian formulas have the form of conditional sentences, and the word "therefore" almost never occurs. Thus, their instances cannot be arguments—at least, not of the usual type. On the other hand, however, Lukasiewicz himself is not very convincing when he argues that the "true" syllogisms are generalized conditionals; on this hypothesis Barbara, for example, would be:

For every A, B, C , if A is predicated of all B and B is predicated

of all C , then A is predicated of all C .

It will be noticed that some of the Aristotelian statements approximate this form, but that others do not. Aristotle's formulations of *Darii* and *Cesare* are not conditionals, and his statement of *Felapton* is clearly metalinguistic. Further, the sense of the word "necessarily," which occurs in nearly every one of the formulas, is not adequately represented by the prefix "For every A, B, C ." Anyway, there is no evidence that Aristotle ever used quantifiers; he seems rather to have thought of variables simply as letters standing in place of terms. Further, a number of passages seem to indicate that, for Aristotle, the syllogisms are *instances* of the formulas containing variables and do not themselves contain variables. All of these obstacles stand in the way of accepting Łukasiewicz's interpretation.

Another, and closely related, difficulty concerns the question whether terms are classes or the names of classes. There are many places in which it appears that Aristotle regards terms as constituents of sentences, the latter being clearly regarded as significant sounds. But there are equally many places where he seems to be thinking of them as classes. Thus, he says "for one thing to be included as a whole in another, and for the other to be predicated of all of the one, are the same." Probably the truth is simply that Aristotle did not honour our much-valued distinctions between the use and mention of linguistic expressions and between arguments and conditional sentences. In asking whether he "really" meant syllogisms to be arguments or conditionals, and whether he "really" meant his logic to concern classes or names, we may be asking questions to which there are no appropriate answers.

The moods of the syllogism are grouped into three figures. Aristotle says that if we want to prove syllogistically that A belongs (or does not belong) to B , we have to take something common in relation to both, and this can be done in three ways: by predicating either A of C and C of B , or C of both, or both of C . "These," he continues, "are the figures of which we have spoken, and it is clear that every syllogism must be in one of these figures." Accordingly, *Barbara*, *Celarent*, *Darii*, and *Ferio* belong to the first figure; *Cesare*, *Camestres*, *Festino*, and *Baroco* to the second; and *Darapti*, *Felapton*, *Disamis*, *Datisi*, *Bocardo*, and *Ferison* to the third. There has been much discussion as to why Aristotle did not anticipate his followers in mentioning a fourth figure, *i.e.*, why he did not consider the possibility of proving A of B by predicating C of A and B of C . Numerous answers, none completely convincing, have been given. In any case, it is probable that Aristotle did recognize the existence of such syllogisms. For he allows interchange of the premisses of a syllogism and says that the result of converting the conclusion of a syllogism is again a syllogism; applying these operations to *Barbara*, *Celarent*, and *Darii* we obtain the moods *Bramantip*, *Camenes*, and *Dimaris* of the fourth figure. The remaining valid moods in this figure, *Fesapo* and *Fresison*, are given explicitly, although with their premisses in reversed order.

As I. M. Bochenski observed, "the assertoric syllogism is probably the most important discovery in all the history of formal logic, for it is not only the first formal theory with variables, but it is also the first axiomatic system ever constructed." (I. M. Bochenski, *Ancient Formal Logic*, North-Holland Publishing Company, 1951.) Aristotle axiomatizes his syllogistic in several ways. In the first of these he chooses as axioms the syllogisms of the first figure. They are said to be "perfect," *i.e.*, intuitively evident. He then proves the validity of the syllogisms in the second and third figures by reducing them to syllogisms of the first figure. The reductions are of two sorts: direct reduction and *reductio ad impossibile*. Direct reductions are made by converting one or more premisses of the syllogism to be proved, reversing their order if necessary, and then deriving the desired conclusion (or its converse) by means of the syllogism to which reduction is made. By this procedure Aristotle reduces *Cesare* and *Camestres* to *Celarent*; *Festino*, *Felapton*, and *Ferison* to *Ferio*; *Darapti*, *Disamis*, and *Datisi* to *Darii*. (See the translations above.) The other method proceeds as follows: from one of the premisses and the contradictory of the conclusion of the syllogism to be proved, one derives

(using the syllogism to which reduction is being made) the contradictory of the other premiss, thus establishing that the conclusion follows from the premisses. Aristotle uses this method to reduce *Baroco* and *Bocardo* to *Barbara*. Then, after reducing all of the moods to those of the first figure, he further states that *Barbara* and *Celarent* alone would suffice as axioms. He proves this by showing how to reduce *Darii* and *Ferio* to syllogisms of the second figure and by reminding us that all syllogisms of the second figure are reducible to *Barbara* and *Celarent*. (We are told that *Festino* may be proved by a *reductio ad impossibile* to *Celarent*, as well as by a direct reduction to *Ferio*.) Elsewhere he observes that the moods of any of the three figures will serve equally well as axioms.

Aristotle arrives at the valid moods by a process of elimination. To show that there is no valid syllogism of a given type, he always produces a counter-example. He does this in a particularly expeditious manner, managing to deal with several possibilities at a time. We quote and explain a typical example.

But if M is predicated of all N and O , there will not be a syllogism. Terms for the affirmative relation are substance, animal, man; for the negative relation substance, animal, number.

This is a condensed argument to show that in the second figure there is no valid mood of the form "If M is predicated of all N and O , then . . ." It makes tacit use of the fact that any substitution of terms for variables which converts the premisses of a valid mood into true sentences will also convert the conclusion into a true sentence. Now suppose there were a valid mood with the indicated premisses and a negative conclusion. Then any substitution of terms for variables which makes the premisses true will also make this negative conclusion true, and will therefore make false the universal affirmative formula " N is predicated of all O ," which is the contradictory of the particular negative and the contrary of the universal negative. But, as a matter of fact, substitution of the terms "substance," "animal," and "man" for " M ," " N ," and " O ," respectively, makes the premisses and this universal affirmative formula true. Therefore, there is no valid mood with the indicated premisses and a negative conclusion. Analogously, since substitution of the terms "substance," "animal," and "number" makes the premisses and the universal negative formula " N is predicated of no O " true, there cannot be an affirmative conclusion. Therefore, there is no valid mood of the type under consideration. Often Aristotle does even better than this, dealing simultaneously with two pairs of premisses and thus eliminating eight possibilities at once.

After sifting out the valid moods of the syllogism Aristotle proceeds to make certain general remarks about them. He notices that in every syllogism at least one of the premisses must be affirmative and at least one must be universal. He points out further that a universal conclusion occurs only when both premisses are universal, while a particular conclusion may follow from premisses which are both universal or one of which is particular. Also, at least one of the premisses must be like the conclusion in being affirmative or negative. Many other less interesting points are made, such as that only *Barbara* has a universal affirmative conclusion.

We have confined our attention to the assertoric syllogism, *i.e.*, to such syllogisms as contain only assertoric components. Actually much the greater portion of *Prior Analytics* I is devoted to modal syllogisms, which contain problematic or apodictic premisses or both. Aristotle develops the theory of such syllogisms in a manner similar to that used for the assertoric syllogisms. However, his treatment is incomplete and contains many errors, and the already complex subject is further complicated by the fact that he uses the modal operators "necessary" and "possible" in a number of different senses, some of which are very difficult to grasp. His contribution to modal logic is undoubtedly important, but a great deal of work remains to be done before it can be regarded as well understood.

The remainder of the *Prior Analytics* and all of the *Posterior Analytics* are devoted primarily to subjects which are not relevant to logic as presently conceived. The same is true of the *Topics* and the *Sophistical Refutations*. In the *Posterior Analytics* Aristotle investigates the nature of scientific knowledge. The *Topics*

attempts to lay down rules for arguing dialectically, *i.e.*, for establishing desired conclusions syllogistically from generally accepted premisses, and the *Sophistical Refutations* consists of a laborious discussion of fallacious arguments. Yet throughout these works there occur incidental remarks which, as Bocheński has shown, reveal that Aristotle was aware of many non-syllogistic laws of logic, including examples from what would now be described as the theory of identity and the calculi of predicates, relations, and propositions. Indeed, the science of logic has very few branches of which the beginnings, albeit sometimes faint, cannot be found somewhere in his writings.

2. Theophrastus.—Theophrastus, Aristotle's successor as head of the Peripatetic school, was evidently a logician of considerable ability. Unfortunately, we possess only a few fragments of his logical works, and in many of these his name is linked with that of his successor, Eudemos. These fragments, however, suffice to show that his work consisted mainly in the development and correction of Aristotelian doctrine. We know but few details. To the first figure of the assertoric syllogism he added five moods which, when the order of their premisses is reversed, are seen to be precisely the five moods of the fourth figure. (Lukasiewicz conjectures that he was led to do this by defining the first figure as that in which the middle term is the subject of one premiss and the predicate of the other.) He expressly identified the indefinite sentences with the particular. He objected, for some reason or other, to Aristotle's use of "*A* does not belong to some *B*" and "Not: *A* belongs to all *B*" as synonymous. Further, it may be conjectured that he used something like the Euler diagrams for the syllogism, since he paraphrases "No *S* is *P*" as "*S* is separate from *P*."

However, Theophrastus' most significant contributions were in the field of modal logic, where, according to Bocheński, he made two major changes: (1) the interpretation of "possible" as "not self-contradictory" instead of "contingent"; (2) the affirmation and consistent application of the principle that the conclusion always follows the weaker premiss. It is also likely that his investigations into hypothetical syllogisms anticipated, to some extent, the Stoic logic of propositions.

3. Stoics and Megarians.—In many respects ancient logic reached its zenith in the writings of the Stoic and Megarian logicians. The Megarian school was founded by Euclid, one of the followers of Socrates. Among his pupils were Eubulides, to whom the Liar paradox is ascribed; Ichthyas, the successor of Euclid as head of the school; and Thrasymachus of Corinth, the teacher of Stilpo. The best-known pupil of Stilpo was Zeno (*c.* 350–260 B.C.), founder of Stoicism. Zeno's successors were Cleanthes and Chrysippus, the latter of whom was the most productive logician of the school. ("If there had been no Chrysippus, there would have been no Stoa"; "If there is any logic in heaven, it is the logic of Chrysippus.") Another important branch of the Megarian school consisted of Eubulides, Apollonius Cronus, Diodorus Cronus, and Philo. Unfortunately, the writings of all these men have been lost, and it is therefore necessary for us to depend upon fragments quoted by later authors. The best of our sources are Sextus Empiricus and Diogenes Laërtius, although we also get bits of information from Cicero, Gellius, Galen, Boëthius, Apuleius, Alexander and the other Greek commentators, Origen, Proclus, Stobaeus, Epictetus, Seneca and a few others. Of these, only Epictetus and Seneca were favourably inclined toward Stoicism, and they were not interested in logic. The result is that our knowledge of the Stoic-Megarian logic has to be obtained principally from persons who were trying to show that it was of no value.

Nevertheless, the picture which can be pieced together from these fragmentary sources is one of a relatively sophisticated and formalized logic quite different from that introduced by Aristotle. It is a logic of propositions, while the syllogistic is a logic of classes or terms; *i.e.*, the values of the Stoic variables are propositions; those of the Aristotelian variables are terms or classes. Further, it is a logic of valid inference schemas, while the Aristotelian formulas are usually propositional forms of conditional type. Stoic-Megarian logic is very modern in a number of important respects. The usual sentence connectives are interpreted truth-functionally, as is customary nowadays, and various possibilities of

defining them in terms of one another are noticed. Arguments are sharply distinguished from the corresponding conditional propositions. The inference schemas which make up the calculus are never confused with the meta-rules for their reduction to one another. The whole logic is conceived in terms of a semantic distinction very similar to G. Frege's distinction between the sense and the denotation of linguistic expressions. In general, it is drawn upon lines very familiar to modern students of the subject.

Stoic semantics rests upon a fundamental distinction among three things: (1) the linguistic sign or sound, *e.g.*, the name "Dion," (2) the existent object denoted by the sign, which in this example would be Dion himself, and (3) the meaning of the sign. The first two of these three things are always bodies, say the Stoics, but the third factor is not a body. It is what Greeks but not Barbarians are able to grasp when they hear Greek words spoken. The technical term for these meanings or senses is "Lekta." On the Stoic view, it is with Lekta, and not with the linguistic expressions thereof, that logic is concerned.

The Lekta are classified in great detail. First, they are divided into deficient and complete. The deficient Lekta are subjects and predicates, a subject being the sense of a proper or class name, while a predicate is the sense of a verb. Complete Lekta are propositions, questions, imperatives, oaths, salutations, etc. Of course, the interest of logic is confined to propositions, which are defined as complete Lekta which are assertoric. They are elsewhere differentiated from other complete Lekta by the property of being true or false. A proposition is the sense of a declarative sentence; if atomic (*see below*) it is somehow composed of the subject and predicate which are the senses of the components of the sentence.

Propositions are divided into atomic and molecular. An atomic proposition is composed of subject and predicate without the help of a logical connective. A molecular proposition always contains at least one connective and consists either of two occurrences of a single proposition (as in "If it is day, then it is day") or of different propositions (*e.g.*, "If it is day, then it is light"). Atomic propositions are either definite (*e.g.*, "This man is walking"), indefinite (*e.g.*, "Somebody is walking"), or intermediate (*e.g.*, "Socrates is walking"). Types of molecular proposition include the negation, conditional, conjunction, disjunction, and several others. The negation of a proposition is said to be formed by prefixing "not," and emphasis was placed upon "prefix." (What this spatial terminology can mean when applied to propositions, as contrasted with sentences, is not explained.) Thus, they said, the correct negation of "It is day and it is night" is "Not both: it is day and it is night," which is of course quite different from "It is day and it is not night." A conditional proposition is one that is formed from two occurrences of a single proposition or from different propositions by means of the connective "if" (*e.g.*, "If it is day, then it is light"). The part immediately following the "if" is the antecedent, and the other part is the consequent, even when the conditional is stated backwards, *e.g.*, "It is light if it is day." A conjunction is a molecular proposition compounded by means of the connective "and," *e.g.*, "It is day and it is light." Similarly, the parts of a disjunction are joined by "or," *e.g.*, "It is day or it is light."

There was a great controversy among the Stoics and Megarians about the meanings of conditionals. Callimachus reports, "Even the crows on the rooftops are discussing the question as to which conditionals are true." Sextus states and illustrates the four main proposals. He arranges these from the weakest (material implication) to the strongest, at each step cleverly producing an example which is true in all the preceding senses but false in the sense at hand.

For Philo says that a true conditional is one which does not have a true antecedent and a false consequent; *e.g.*, when it is day and I am conversing, "If it is day, then I am conversing"; but Diodorus defines it as one which neither is nor ever was capable of having a true antecedent and a false consequent. According to him, the conditional just mentioned seems to be false, since when it is day and I have become silent, it will have a true antecedent and a false consequent; but the following conditional seems true: "If atomic elements of things do not exist, then atomic elements of things do exist," since it will always have the false antecedent, "Atomic elements of things do not exist," and the true consequent, "Atomic elements of things do exist."

And those who introduce "connection" or "coherence" say that a conditional holds whenever the denial of its consequent is incompatible with its antecedent; so that, according to them, the above-mentioned conditionals do not hold, but the following is true: "If it is day, then it is day." And those who judge by "suggestion" declare that a conditional is true if its consequent is in effect included in its antecedent. According to these, "If it is day, then it is day" and every repeated conditional probably will be false, for it is impossible for a thing to be included in itself.

It will be noticed that Philo has defined what is now called "material implication." This definition seems to have been the one which found the greatest favour with the Stoics. It occurs in many of the fragments, sometimes even in what amounts to truth-table form:

Since, then, there are four possible combinations of the parts of a conditional—true antecedent and true consequent, false antecedent and false consequent, false and true, or conversely true and false—they say that in the first three cases the conditional is true (*i.e.*, if the antecedent is true and the consequent is true, it is true; if false and false, it again is true; likewise, for false and true); but in one case only is it false, namely, whenever the antecedent is true and the consequent is false.

The view of Diodorus is not as clear as that of Philo, but from his definition of the "possible" as "that which either is or will be true" we can determine that a conditional holds in the Diodorean sense if and only if it holds *at all times* in the Philonian sense. For example, "If it is day, then it is light" holds in the Diodorean sense provided that for every value of *t* the propositional form "If it is day at time *t*, then it is light at time *t*" is a true Philonian conditional. The third sense mentioned in Sextus' list is what is now called "strict implication"; the fourth is nowhere taken up again.

Two basic types of disjunction were recognized by the Stoics: exclusive and inclusive. Exclusive disjunction was most used, and it is the only type of disjunction involved in the Stoic calculus of propositions. An exclusive disjunction is true if and only if exactly one of the disjuncts is true, *e.g.*, "It is day or it is night." For inclusive disjunction we possess no clear truth-functional definition, but there are illuminating examples, such as "Socrates is walking or Socrates is conversing." There seem also to have been non-truth-functional definitions, according to one of which a disjunction is not true unless the disjuncts are incompatible. As to conjunction, the case is simpler. A conjunction is true if and only if both parts are true. A negation is true if and only if what is negated is not true.

Chrysippus, in reference to the statement "If anyone is born under the Dog Star, then he will not drown in the sea," recommends that it be expressed as follows: "Not both: someone is born under the Dog Star and he will drown in the sea," thus showing that he knew how to express material implication by means of negation and conjunction. There is also some evidence that the Stoics knew how to define exclusive disjunction in terms of negation and equivalence.

As with Aristotle's syllogistic, however, the most interesting aspect of the Stoic logic of propositions is its arrangement into a deductive theory. The elements of the Stoic theory are arguments, not propositions, where an argument is regarded as a system of propositions containing premisses and a conclusion. Arguments of five types are taken as basic, and all others are declared provable in terms of these. The basic types are represented by the following five schemas:

- I. If the first, then the second.
The first.
Therefore, the second.
- II. If the first, then the second.
Not the second.
Therefore, not the first.
- III. Not both the first and the second.
The first.
Therefore, not the second.
- IV. The first or the second.
The first.
Therefore, not the second.
- V. The first or the second.
Not the first.
Therefore, the second.

For an example of a proof in the system, consider the following schema:

1. If both the first and the second, then the third.
 2. Not the third.
 3. The first.
- Therefore, not the second.

The Stoic proof given by Sextus makes use of the following meta-rule: "If we have premisses which yield a conclusion, then we have in effect also the conclusion among the premisses, even if it is not explicitly stated." From 1 and 2, by a basic argument of type II, we get

4. Not both the first and the second.

which, according to the meta-rule, can now be considered as one of the premisses. From 3 and 4 we then obtain the conclusion by a basic argument of type III.

We know that there were four meta-rules by means of which such proofs were to be carried out. Unfortunately, we possess only two (or possibly three) of these rules. The first was "If from two propositions a third is deduced, then either of the two together with the denial of the conclusion yields the denial of the other," and the third was "If from two propositions a third is deduced and there are propositions from which one of the premisses may be deduced, then the other premiss together with these propositions will yield the conclusion." Perhaps the rule used in the example above is another version of this one. The Stoics seemed to think that their system was complete, *i.e.*, that every valid argument in the calculus could be reduced to a chain of arguments of the five basic types. Without knowing all four of the meta-rules we are not in a position to evaluate this claim.

Examples of Stoic proofs are very few in number. However, numerous arguments are mentioned and schematized without proof. For instance, there is the schema

- Either the first or the second or the third.
Not the first.
Not the second.
Therefore, the third.

Chrysippus said that even dogs make use of this sort of argument. For when a dog is chasing some animal and comes to the junction of three paths, if he sniffs first at the two paths down which the animal did not run, he will rush off down the third path without stopping to smell. Another schema is

- If the first, then the second.
If the first, then not the second.
Therefore, not the first.

A Stoic example of an argument of this type is

- If you know that you are dead, then you are dead.
If you know that you are dead, then you are not dead.
Therefore, you do not know that you are dead.

The Stoic and Megarian logicians, like logicians of all times, were greatly interested in paradoxes, the most famous of which was the Liar. This important antinomy was the subject of much writing in antiquity, including perhaps 28 books by Chrysippus alone. In fact, there is an ancient epitaph which says that Phileas of Cos died from spending his nights thinking about it. The Liar appears in several forms. Alexander gives "The man who says 'I am lying' is both telling the truth and lying." Cicero's version is "If you say that you are lying and tell the truth, then you are lying." Gellius asks, "When I am lying and say that I am lying, am I lying or telling the truth?" A closely related paradox, often called "the Epimenides," first appears in the Apostle Paul's *Epistle to Titus*. Paul there reminds Titus that even the Cretan prophet (identified by commentators as Epimenides) said that all Cretans were liars, gluttons, and evil beasts. He adds that what Epimenides said was *true*! No clear solution to any of these formulations is to be found in extant ancient literature.

4. The Last Period.—The history of ancient logic after Chrysippus is a subject still awaiting exploration in the second half of the 20th century. In the imperfect state of knowledge it appears that there were no logicians worthy of being mentioned in the same breath with Aristotle, Diodorus and Chrysippus. The period was not a creative one, new problems and methods being entirely

lacking, and what literature there was consisted primarily of commentaries and compendiums. In this connection, the contemporaries Galen and Apuleius (c. A.D. 150), whose handbooks are extant, deserve mention. Among the commentators, Alexander of Aphrodisias, a Peripatetic of the 3rd century A.D., was clearly a competent logician. His commentary on the *Organon* remains down to the present as perhaps the best exegetical account of this work. Of the later Greek commentators on Aristotle, Simplicius must be listed as one of the few who wrote intelligently about matters of logic. Martianus Capella, author of a Latin handbook of great importance for the transmission of ancient logic to later times, should also be mentioned.

Anicius Manlius Severinus Boëthius (c. A.D. 480-524), the last Roman philosopher, was not a very good logician but is nevertheless highly important because of his influence on the middle ages. He wrote a number of books on logic, including *De Syllogismo Hypothetico*, *De Syllogismo Categorico*, and the commentaries on *De Interpretatione*. In these works we find Aristotelian logic presented in a terminology and manner now known as "traditional." Thus, the syllogisms are stated as arguments and not in conditional form. The Square of Opposition appears in its usual form, and many other details of classical logic occur for the first time in Boëthius.

In the *De Syllogismo Hypothetico* we find a number of formulas best interpreted as theorems or rules of the propositional calculus. Some of them appear to be absurdly erroneous, but Van den Driessche has shown that Boëthius occasionally used "if" in the sense of material equivalence. In the light of this explanation, such formulas as

If not-*a*, then *b* implies *c*: but
b implies *c*; therefore, not-*a*.

are seen to be valid, after all.

With Boëthius, ancient logic comes to a close. (B. Ms.)

II. LOGIC IN INDIA

1. Origins.—The origins of formal logic in India lie in exegesis and debate. By perhaps the 4th century B.C. the school of exegetes or interpreters of Vedic texts (*mīmamsa*) began to furnish technical terms and a few basic concepts that were to be used later in logic. Actual logical operations are first found in the patterns of debate, called in some schools *nyaya*, which crystallize about the 2nd century B.C. The opening argument of the Buddhist *Kathavatthu* of this period falls into such a formal pattern. It contains a refutation that may be summarized thus:

If my first statement (*a*) was true, then you should consent to my second (*b*). You are wrong to say that *a* is true but *b* is not true. If *b* is not true, then *a* is not true. You are wrong to say that *a* is true but *b* is not true.

This is certainly an approach to propositional logic, as Stanislaus Schayer has pointed out. But it is consistent with the practical nature of such texts that while logical operations are actually performed no general rules are yet given for their performance.

These patterns of debate were often very lengthy, their form being chosen for psychological or rhetorical effect. According to the Jain author Bhadrabahu (1st century B.C.) the best pattern is one of ten members, which he lists as follows: (1) general thesis, (2) particular thesis, (3) general reason, (4) particular reason, (5) counter-argument, (6) denial of the counter-argument, (7) example, (8) doubting the example, (9) laying the doubt, (10) conclusion. It is from such a pattern as this that the classical Indian syllogism, likewise called *nyaya*, arises.

2. The Old Nyaya (Pracina-nyaya).—The major school of Indian logic takes its name from the syllogism. The oldest writings of the school, the *Nyayasutras*, may go back to the time of Christ but acquired additions perhaps as late as A.D. 200. The early period of the school is characterized by intense and beneficial argument between orthodox (Hindu) and Buddhist logicians. Important contributions to logic were also made by the physicists (*vaiśeṣika*) in the early period and from the 5th century onward by the Jains.

The classical Indian syllogism is found in the earliest Nyaya

texts. It consists of five members and shows clearly its origin from a pattern such as Bhadrabahu's (see above). It has become a syllogism by the expansion of the "example" to include a statement of universal concomitance or pervasion (*vyapti*). In the following example the particular argument is directed against the exegetes, who claimed that the word of the Veda is eternal.

1. Thesis: Word (is) non-eternal,
2. Reason: because (it possesses) the property of being produced.
3. Example: What possess(es) the property of being produced (is) seen to be non-eternal, as a pot. What possess(es) the property of not being produced (is) seen to be eternal, as the soul.
4. Application: It (viz., word) (is) like this (viz., possesses the property of being produced).
5. Conclusion: Therefore, word (is) non-eternal.

The original of the above contains no finite verb. According to commentators the last three members only are assertions. In the first two the terms are simply brought together without anything yet being asserted of the truth or falsity of the collocation.

This syllogism contains three parts (*ansa*) or terms. (1) The *paksha* (field), viz., the subject of thesis and conclusion. It is called a field because the other two parts occur (*vartete*) in it. In the above example *paksha* = word. (2) The *hetu* (reason proper). In the example *hetu* = the property of being produced. (3) The *sadhya* (that which is to be proved). The early Nyaya argues about just what the *sadhya* is, e.g., whether in the above example it is "the non-eternality of word" or "word-as-non-eternal" or, what was finally agreed on, simply "non-eternality."

This analysis shows how the classical Indian syllogism differs both from those of Aristotle, the terms of which are classes, and from the formulas of propositional logic. The *paksha* is normally a single individual; *hetu* and *sadhya* are regularly properties, expressible in Sanskrit by an abstract noun. The translation of the third member as " $F(x) \supset G(x)$ " may refer to the same facts in a given instance as the Indian original, but the facts are not arranged in the Indian way. The letter *F* refers by an indissoluble expression to two notions which are quite distinct to the Indian logician: the *hetu* and the relation by which the *hetu* occurs. In the later development of Nyaya either of these notions may be qualified independently of the other.

The Buddhist Vasubandhu (4th century A.D.) distinguishes between inference for others (*pararthanumana*, i.e., formal debate), which requires the presence of all five members, and inference for oneself (*svarthanumana*), which requires only the first three. The syllogisms of later textbooks are regularly given in the three-membered form. Prasastapada the physicist and the Buddhist Dinnaga (both c. A.D. 400) give systematic lists of fallacies.

Dinnaga is the first to give a "wheel of reasons" (*hetucakra*), that is, a systematic list of possible *hetus*. His list is based on the distribution of the *hetu* with respect to the *sapaksha* (objects other than the *paksha* but like it in being loci of the *sadhya*) and the *vipaksha* (objects other than the *paksha* and unlike it in not being loci of the *sadhya*). There are nine possible distributions, as the *hetu* may occur in all, part of, or none of either of these areas.

This wheel of reasons is vastly increased by Uddyotakara (c. A.D. 600) of the orthodox Nyaya, who gives 176 possible *hetus*. The increase is occasioned in the first instance by the addition of cases where *sapaksha*, *vipaksha*, or both simply do not exist. Thus, as an example of the third type: "Everything is eternal, because it (is) an object of knowledge." Other refinements of Uddyotakara are to distinguish cases where the *hetu* occurs in all, part, or none of the *paksha* itself, where the *hetu* is complex, e.g., "Word (is) non-eternal, because while it (is) nameable it (is) an object of knowledge," etc.

The Buddhist Dharmakirti (7th century) propounds a further division of *hetus* into: (1) Those which possess a common nature with the *sadhya*, e.g., "This is a tree, because it is a *Simsapa* (tree)." (2) Those which are an effect of the *sadhya*, e.g., "This hill possesses fire because it possesses smoke." (3) Those which are cases of nonperception, e.g., "There are no *Simsapas* here, because we perceive no trees." It is of this third class, which includes

inferences from negative premisses and inferences leading to negative results, that Dharmakīrti's analysis is most elaborate. He lists 11 varieties.

The Old Nyaya is summed up from an orthodox standpoint by Vacaspati Misra, who wrote his *Nyayasucinibandha* in A.D. 976. The date A.D. 841, given in many books, is due to an error in identifying the era.

3. The New Nyaya (Navya-nyaya).—Udayana (11th century) and others were instrumental in altering the Nyaya to the form which it assumes in the hands of Gangesa (14th century according to the evidence adduced by Dinesandra Bhattacharyya). Gangesa for the first time expressly refers to his school as the New Nyaya. In the centuries which followed, other schools also contributed to logic, notably the pluralistic Vedānta of south India (e.g., Jayatīrtha and Vyasatīrtha), the neogrammarians (e.g., Nagesa Bhatta), and the Jains. The following account is limited to the New Nyaya since its contributions appear to be the most important.

The chief innovations of the New Nyaya are three: a new method of universalization, rendered possible by the concept of limitation (*avacchedakata*); the discovery of a number of laws similar to the theorems of propositional logic; a new interest in the definition of relations and the use of these relations in operations of considerable complexity.

The method of universalization springs from a dissatisfaction which had always been felt with quantifiers. "All things which possess smoke possess fire" had troubled even the old logicians and for more reasons than one. There was the formal difficulty of binders. Mountain fire does not occur in a kitchen nor kitchen fire on a mountain. Deeper than this was a problem of knowledge. Even if interpreted without cross-connection, such statements refer to facts which the Naiyayikas claim are impossible to be known except by inference. And inference cannot serve as the basis for inference. What we perceive, say the Naiyayikas, are the generic principles (*jati* or *vibhajakopadhi*) that reside in the individual manifestations with which the senses come in contact. If a universal statement is to serve as the basis of inference, it should be phrased in accordance with the facts presented by perception. The New Nyaya method of so phrasing statements appears clumsy in English translation and can best be shown by a graduated example.

For "All that possesses smoke possesses fire" let us first substitute the equivalent expression "No case of smoke occurs in what is not a locus of fire." And for this let us substitute again: "The absence of smoke which occurs in the locus of a generic absence of fire is a generic absence." The terms to be universalized are now (a) generic absence of fire and (b) generic absence (of smoke). Absence *a* is said to be such that its counterpositiveness (*pratiyogita*, the nature of the thing which it denies) is limited (*avacchinna*) by fireness (*vahnitvavacchinna-pratiyogitanirupitabhava*). That is to say, we are denying not this or that case of fire but any case you choose of an entity inhered in by fireness. Absence *b* is said to be an absence whose counterpositiveness is limited by smokeness.

Notice that in these substitutions, which sound so clumsy in English, the Sanskrit expression is a single compound word. The literal rendering of *vahnitvavacchinna-pratiyogitanirupitabhava* would be fireness-limited-counterpositiveness-described-absence. It is this syntactical peculiarity which allows the New Nyaya to operate with such terms somewhat as the modern logician operates with the symbols *p* and *q* or *F* and *G* where these symbols stand for whole propositions or functions. Accordingly, we find in the New Nyaya definitions of conjunction, disjunction, and implication which cover the facts referred to by sentence connectives as well as class connectives. One must bear in mind, however, that a translation of these definitions into logic notation is never an exact one. The New Nyaya units are never precisely propositions or classes; they are the referenda of abstract nouns. New Nyaya techniques are parallel in many respects to those of modern logic: thus, where the western mathematician or logician speaks of a class of classes the Naiyayika speaks of the abstract of an abstract; but parallel lines do not actually meet.

This New Nyaya method of universalizing by abstraction offers a quite satisfactory substitute for quantification so long as the number of terms and length of operations is not too great. Limits are imposed by human memory and corporeal breath but these limits are fairly wide. In formal debate Naiyayikas of the present day will use words that run to 300-400 syllables and take more than a minute each to pronounce.

As counterpositiveness is limited by an abstract determining the nature of the entity denied, so are causeness, effectness, etc., limited by abstracts which determine or show the precise selection of things caused or effected. A further step is taken by the technique of relational limitors. The counterpositiveness of absence limited by fireness is said to be limited also by the relation of contact when we deny the presence of fire in a locus such as hearth, by a relation of objectivity if we deny that fire is an object of knowledge, by identity if we deny that fire is water, etc. In this way the New Nyaya comes to investigate the relations between entities, and by simplifying all complex relations into chains of relations of two terms each, it is able to analyze situations of considerable complexity.

The New Nyaya reaches its height of analytical power with Raghunatha Siromani (c. 1475-c. 1550). This philosopher is so famous for the innovations he introduced in metaphysics, where he overthrew Nyaya tradition for a system much closer to Vedānta, as he is for his logic. Raghunatha constructs definitions of concomitance and pervasion (*vyapti*) that will fit cases of compound and complex *hetu* and *sadhyā*. In his analysis of relations he comes on a discovery of the true nature of number. It is typical of his school that he does not distinguish abstracts or classes (e.g., pairs, triples) from the corresponding cardinal numbers (e.g., 2, 3). He distinguishes the relation by which twoness is connected with the components of pairs (the relation of inherence) from the relation by which twoness is connected with the pairs as abstracts. The latter relation, called *pariyapti* (which may be translated literally by coining the phrase "circumtaining relation"), corresponds to what Frege in 19th-century Europe expressed by saying that a number belongs to a concept; it represents in another form Frege's insight that, e.g., the number 2 should be attached to the concept, *satellite of Mars*, rather than to the concrete physical objects, Deimos and Phobos.

The creativeness of the New Nyaya, like that of all schools of Indian philosophy, declines from the beginning of the 18th century, but competent Naiyayikas and a few brilliant ones are still to be found in Benares, Calcutta, Mysore and in the district of Nadia in Bengal, the birthplace of Raghunatha.

(D. H. H. I.)

III. SCHOLASTIC LOGIC

Medieval scholastic logic is characterized by its dependence on classical tradition, by its use of the Latin language and by the influence of Christian theology. While tradition and the Latin language had a more direct bearing on its formation and development, theology influenced it rather indirectly, partly by demanding a well-developed logic for the discussion of theological questions, partly by posing a few logical and semantical problems of its own; for example, the problem of the truth or falsity of propositions concerning future contingent facts, or the problem of the formality of logical discourse in terms of the divine Persons of the Holy Trinity. The Latin language, however, was of far greater importance than theology in the development of medieval logic. Essentially and entirely, the logic of the schoolmen was based on a "natural" language which, with the help of the grammarians (mostly Priscian and his medieval disciples like Elyas), was analyzed, reduced to rules and adapted to the needs of logic. Consequently the language of scholastic logic is richer, or rather more complicated and more involved in the subject matter, than the artificial languages of modern logic. But above any other factor, it was tradition that guided the development of scholastic logic.

Primarily through Boëthius and Apuleius, the early schoolmen believed themselves in uninterrupted contact with ancient logic. What they actually had, however, was but a fragment of the whole.

It was only toward the end of the 12th century that the total body of Aristotelian logic became known; and at the same time the Arabian philosophers—notably Averroës, the great commentator on Aristotle—became available to the schoolmen, while elements of Stoic logic still continued, transmitted primarily from Cicero through Boëthius and Apuleius.

By way of summary, it can be said that scholastic logic began to develop in the 12th century, reached maturity in the 14th and 15th centuries, and declined rapidly from the 16th to the 18th centuries. It is impossible to fill this bare outline with complete details. Modern scholars, thanks to the pioneer work of Jan Lukasiewicz, were, at mid-20th century, only on the verge of bringing to light the highly developed logic of the 14th and 15th centuries—a logic that up to a few decades before had been completely lost.

1. Period of the "Old Logic" (*Ars Vetus*).—Fragments of ancient logic were transmitted to the scholastics through the works of the church fathers, primarily St. Augustine. The main sources, however, were Porphyry's *Isagoge*, or *Introduction to the Categories of Aristotle*, and the *Categories* and *Perihermenias* (*De Interpretatione*) of Aristotle.

Later, when other logical treatises of Aristotle became known, these three works were grouped together under the title of *Ars Vetus* (Old Logic), while the newly discovered works were called *Ars Nova* (New Logic).

Another part of the logical heritage from antiquity was Cicero's *Topics*, to which must be added the commentaries of Boëthius on the works included in the *Ars Vetus*, his *Introduction to the Categorical Syllogism*, his treatises *On Topical Differences* and *On Hypothetical Syllogisms* and a few minor works, together with the *Perihermenias* of Apuleius of Madauros who also treated the categorical syllogism.

Thus the logicians of the early middle ages—thanks to Cassiodorus and the Benedictine monks who preserved what they could of ancient learning—had at their disposal a classification of terms; a theory of definition and division; an analysis of sentences; the truth and falsity both of simple categorical sentences and of modal sentences and a theory of their oppositions, a theory of the categorical syllogism and of the hypothetical (mostly conditional) syllogism; and a theory of dialectical or topical inferences. Through Cicero, Boëthius, and Apuleius, fragments of Stoic logic were also available to the early scholastics, and Apuleius provided the additional help of a primitive systematization of logic. The most conspicuous deficiency of early medieval logic, measured according to the standard of Aristotelian logic, was the lack of any treatment of the modal syllogisms and of any theory of demonstration.

The history of logic from the end of the ancient world up to the 11th century can be summarized in the one main fact that this partial legacy from antiquity was at least tenaciously preserved and slowly and thoroughly absorbed.

The real development of scholastic logic began with Peter Abelard (1079–1142) and his school. Although contemporary writers speak much of the great activity in logic during this time, and although many logical tracts are still extant in manuscript, little is actually known about the logic of the period. Abelard's *Glosses to Porphyry*, the *Categories* and *Perihermenias* are the only complete texts edited, and they deal more with semantical and philosophical problems (universals) than with logic. His *Dialectica*, substantial parts of which were published by Cousin, seems completely dependent on Boëthius and Apuleius for its logic; in fact it amounts to little more than a systematization of the Boethian legacy.

There are five parts: (I) On the Parts of Speech (*Oratio*), On the Predicables, On the *Categories*, and On the Content of *Perihermenias*; (II) On Categorical Propositions and Syllogisms, or the *Prior Analytics*; (III) *Topics*; (IV) On Hypothetical Propositions and Syllogisms, or the *Posterior Analytics* (!); and (V) On Divisions and Definitions.

It may be remarked in passing that Abelard was quite aware that it was his logic and his daring application of it to theological problems rather than the scandal of his private affairs that

brought him into conflict with St. Bernard (*Odiosum me reddidit mundo logica*).

John of Salisbury, a disciple of Abelard, and a great admirer of the *Topics* or *Dialectics*, gives in his *Metalogicon* (*Et quia logicae suscepit patrocinium, Metalogicon inscriptus est liber*; ed. by Clemens C. I. Web, p. 3, Oxonii 1929) many details about the enormous activity in logic that was then going on. He mentions Adam of Little Bridge (*de Ponte Parvo*), an Englishman named after the place where he taught in Paris, who also wrote a textbook, an *Ars dialectica* or *Ars discernendi*. He tells a remarkable story about one of Adam's disciples, William of Soissons, who apparently composed a *machina*, a calculus of logic. According to John of Salisbury, this man learned from Adam of Little Bridge certain quite remarkable consequential rules for the proof of which he used his "machine"; for instance: From one impossible (sentence?) every impossible follows. Although John refuses to accept this, it nevertheless seems to be the forerunner of the later scholastic consequential rule: From an impossible anything follows.

There were about 12 handbooks of logic in use at this time, but they seem to have been more or less of the same type. In any case none of them gained general recognition, and none is accessible to us in printed form.

2. Period of the "New Logic" (*Ars Nova*).—Around 1200, according to Alexander Neckam (d. 1217), the school at the Little Bridge in Paris required the reading of the *Ars Vetus*, and in addition, Aristotle's *Topics*, *Sophistical Refutations* and the two *Analytics*, these last constituting the *Ars Nova*. From then on the scholastics had at their disposal the entire *Organon* of Aristotle. They immediately began the work of assimilation, and it can be safely stated that around the middle of the 13th century the whole of Aristotelian logic had been completely absorbed and was being extensively used by the schoolmen, notably also by the theologians.

The process of assimilating the *Organon* was greatly helped by the influx of oriental literature into the Latin occident. Long before the scholastics became acquainted with the whole of the *Organon*, the Arabians, through the help of the Syrians, had absorbed Aristotelian logic. It is said that al-Farabi (d. 950), "the Second Philosopher" (Aristotle being "the First Philosopher," Avicenna, "the Third"), directed his attention largely toward the logic of Aristotle and introduced it into the culture of Islam. He overcame the violent reaction of the Islamic theologians and paved the way for "the Third Philosopher," Avicenna (Ibn Sina, d. 1037 in Persia). The part of Avicenna's *Logic* that was translated into Latin toward the end of the 12th century is but an insignificant fragment of his well-developed treatise. His complete original work never directly reached the scholastics, and like the entire "hellenizing Arabian philosophy," as M. Horten calls it, remained foreign to orthodox Arabian philosophy and theology. Most important, as far as scholastic logic is concerned, was the work of Averroës (Ibn-Rushd, d. 1198 in Spain). His excellent and faithful commentaries—the scholastics used to call him simply "the Commentator"—for which he in turn exploited the earlier Greek commentaries—appeared in the first half of the 13th century at Paris and Oxford.

As far as logic is concerned, it seems that the influence of the Jewish philosophers on the scholastics was nil or at most negligible. Even the classical definition of truth as conformity of thought with reality (*adequatio rei et intellectus*), which Thomas Aquinas attributed to Isaac Israeli, is actually not to be found at all in Israeli's *Book of Definitions*. The formula is of Arabian origin.

Thus, through acquaintance with the culture of the east, the schoolmen obtained access to a wealth of material which they used extensively and well. But parallel to this opening up of sources from Arabian philosophy went the direct contact with the Greek sources of Aristotle and his commentators. Thus the revival of the ancient Aristotelian logic was complete. This abundance of newly acquired material was brought together in the voluminous work of Albertus Magnus. He wrote no sum of logic, to be sure, but he paraphrased the whole *Organon* of Aristotle, including also the additions made by Boëthius, by drawing from the Arabian

sources. How far he went independently beyond this scope is difficult to say at present. His logic, as far as syllogistics and the modal logic is concerned, is essentially that of the Aristotelian commentators.

Several near-contemporaries of Albertus Magnus also made important contributions to the development of logic. Robert Grosseteste (d. 1253), bishop of Lincoln, wrote a commentary to the *Posterior Analytics* which had great influence and was widely used. St. Thomas Aquinas (d. 1274) wrote an important commentary to *Perihermenias*, making use of the translations from the Greek furnished by William of Moerbeke. One of his followers, Giles of Rome (d. 1316), composed valuable commentaries to all the works of the *Organon*. Robert Kilwardby (d. 1279), the fellow Dominican and opponent of St. Thomas, also produced commentaries to logical writings, as did Duns Scotus (d. 1308) and the so-called Averroists such as Boethius of Dacia (c. 1285).

It is not easy to state just how far these logicians went beyond the matter they had at hand. Clearly, their commentaries did not simply repeat or explain, but sifted and developed as well. The confusing state of the Aristotelian logic of modalities, which was keenly felt by some logicians, was to a certain extent overcome by the distinction of Theophrastus' *sensus divisus* or the modality of the thing, and the *sensus compositus*, or the modality of the dictum. A similar advance can be noted in syllogistics in general. From Averroës the schoolmen learned to enumerate all possible combinations in each figure and to eliminate the invalid moods. Beyond this, nothing definite can be said until further research has been completed.

It is worthy of note, however, that these commentaries to the classical treatises strictly followed the line of development presented in the treatises themselves, taking little or no cognizance of the current of Terministic logic that finally absorbed the Aristotelian. This is true even of those commentaries written by logicians who also wrote original tracts completely in line with Terminism.

3. Rise of Terministic Logic.—Genuine scholastic logic did not originate from the revival of Aristotelian logic, but rather had its roots in earlier tradition, inaugurated by Boëthius and Apuleius and developed by Abelard and his successors in constant contact with grammar. It was the logic of speech (*scientia sermocinalis*), in differentiation from, though not in opposition to, the logic of second intentions. This was the logic that remained basic not only in the sense that it was obligatory for beginners, but also in the sense that it was the starting point for an enormous and original productivity in logic. This logic of the Terminists or Summulists took definite shape, as far as is known at present, toward the middle of the 13th century, and was given its classical form by Petrus Hispanus (Peter of Spain, later Pope John XXI, d. 1277), whose famous textbook remained in use until the 17th century. Terminism was developed primarily by the artists (philosophers) rather than by the theologians, who were relatively late in taking the leading part in it; there are, however, traces of Terministic logic in all the great theologians of the 13th century, beginning with Alexander of Hales (d. 1245).

Terministic logic led its own life, was in constant contact with the logic of the commentators, and was confined neither to the Realists nor to the so-called Nominalists, for it was indifferent to metaphysical implications.

Of the numerous *summulae* composed during the 13th century, only two have been printed in modern times—those of William of Shyreswood (d. after 1267) and Peter of Spain—and a few others have been described. Their relation to Apuleius is evident from the fact that all of them start with a discussion of propositions (*Perihermenias*) and include compound propositions. Their indebtedness to the grammarians is obvious from the introduction of semantical problems; their character as textbooks is likewise evident from the introduction of mnemonic verses, some of which have survived up to the present (for instance, *Barbara celarent*), and the discussion of sophismata. The pattern of these textbooks for beginners is essentially the same. They open with a tract on propositions, then deal with terms (at least with the five predicables of Porphyry), then with the categorical syllogism, fol-

lowed by topical rules and ending with fallacies. However, within this framework and sometimes scattered throughout, as in Peter's *Summulae*, there is found a group of additional tracts which constitute the most important contribution of the Summulists. They were called in the middle ages the *Parva Logica*, or the tracts on the properties of terms. These properties are the semantical relations of terms in the context of propositions: *suppositio*, *copulatio*, *appellatio*, *ampliatio*, and *restrictio*, to which are added *distributio* and the corresponding properties of relative terms. *Suppositio* is the use of a term that stands for something in a proposition. According to the older, Realist, logicians, a term signifies that for which it is instituted by convention, that is, for a concept or for a nature; but it stands for (*supponit*) that for which it is actually used in a proposition. Hence *suppositio* is the most general property of a term. The predicate term calls for (*appellat-appellatio*) verification for the time indicated by the tense of the verb; the verb itself and true adjectives have *copulatio* (binding); a term may be restricted (*restrictio*) in its scope by the tense of the verb or by the adjectives, or enlarged (*ampliatio*) in a similar way, and may be distributed (*distributio*) by quantifiers, and refer back to another term when it is a relative pronoun. Thus in the sentence: "Every white man was an animal," the terms "white" and "was" have *copulatio*; "animal" has *suppositio*, for it stands for the nature "animality" in every man; and it also has *appellatio*, since it calls for existing men, but only according to the form of the verb—that is, at some past time it must have been true to say: "This white," pointing at a man who is now or was white, "is an animal." The term "man" is restricted by the adjective "white" to stand for fewer individuals than it is able to stand for alone, and the term "white man" is distributed for every individual man who is white.

Of all these properties, it was *suppositio* that received the fullest treatment and the most extensive development. The *suppositio* (individuals in a broad sense) for which a term can stand are, according to the Realists, either individuals, or the nature signified by the term, or the term itself. In the first case it is called personal *suppositio*, in the second, simple *suppositio*, and in the third material *suppositio*. The first two apply to terms in use, the latter to terms in mention. Further distinctions are made, such as common *suppositio* (of a common term) and discrete (of a singular term or its equivalent); natural *suppositio* (the standing of a common term for anything it can stand for), and accidental *suppositio* (the standing of a common term for that which the context requires). Accidental *suppositio* is either simple or personal, and personal *suppositio* is further subdivided into confused and distributive (when a term stands for every individual), determinate (when a term stands for at least one individual), and confused only (when a term is bound or "immobilized" by the essence signified by another term).

It is obvious that semantical and intensional considerations prevailed among the Summulists, although the foundation for an extensional interpretation was laid and to a certain extent developed. It remained for the following period to develop this fully.

The Summulists' interest in semantical relations also led them to study the syncategorematic terms as distinct from the categorematic, which distinction probably goes back to the Stoics. While categorematic terms have a definite object that they signify by convention, syncategorematic terms (e.g., the conjunctions "and," "or," "if-then," etc., the signs of negation and predication such as "no" and "is," etc., the quantifiers "every," "none," "some," etc.) have signification only with categorematic terms, but not alone. This led the Summulists already to understand them as logical operators or functors (*officiales*), and thus they advanced from a semantical to a syntactical interpretation of them. The great interest of the Summulists in these terms is apparent from the fact that they treated them extensively in several independent tracts, and also by the fact that they gave considerable attention to another type of logical literature, the *Sophismata*, which dealt mainly with the same matter. *Sophismata* (which seem to have originated in the school of Abelard) are not always false arguments; they are rather ambiguous sentences that owe their ambiguity precisely to the syncategorematic terms contained in them.

In the medieval texts they are always treated in the same manner; the *positio* of the sophisma (one sentence) is followed by the *probat* (it is proved) etc., and the *improbat* (it is disproved) etc., and terminated by the *olutio* of the *probat* or of the *improbat* or of both. The study of such tracts was an excellent means of obtaining practice and skill in the application of logical rules.

It may be well to add here that for the same reason—for practice in logic—the so-called *Obligatio* was introduced and developed. *Obligatio* has almost the same meaning as axiomatics in the modern sense, for the *Respondens* binds himself to the acceptance of a proposition and its consequences, and has to guard against the contradictions in the original sentence (the *positio* or *petitio*) or its opposite (the *depositio*), and in the consequences assuming pertinent or impertinent sentences. One kind, the *impositio*, deals with the use of symbols (for propositions or terms) and its limitations.

4. Classical Period of Scholastic Logic.—The classical period of scholastic logic which began, roughly speaking, c. 1300, achieved the synthesis of the entire Aristotelian logic with the Terministic logic and systematized that synthesis on the basis of consequential rules. It is impossible to mention the names of all those who deserve credit for this splendid accomplishment, but at least a few of the greatest among them require some comment.

It is becoming more apparent, as research progresses, that the main impetus of the new movement came from Oxford—or in any case from England—with Roger Bacon (d. after 1292) as a forerunner. Sutton, perhaps the Dominican Thomas Sutton (c. 1300), composed a tract on consequential rules which was quoted and commented on later by Albert of Saxony. Judging from Albert's comments, the tract was marked by a high degree of formality. The two outstanding men of this period, however, were the so-called Nominalist, William Ockham (Occam), and the Realist, Walter Burley. They had immediate followers among equally great logicians, partly at Oxford, where the Mertonians (William Heytesbury; Richard Swineshead, "the Calculator," who was highly praised by Leibniz; John Dumbleton; Ralph Strode; and Richard Ferabrich) held sway; and partly at Paris, where Jean Buridan and Albert of Saxony were leaders.

Ockham (c. 1300–1349) composed three sums of logic, two of which are still unedited. The first and longest is known as the *Summa Logicae*. It is written not for beginners, but for theological students, and as such is a work of maturity. In the spirit of the Terminists, Ockham arranges the entire *Organon* of Aristotle into three parts: (I) On Terms; (II) On Propositions; (III) On Argumentation (the syllogism in general, the demonstrative syllogism, the Topical rules, the fallacies). To the first section are added the *Parva naturalia*; to the second, a discussion of compound propositions; to the third, after the Topical rules, a tract on *Obligatio* is added. Ockham gives only brief mention to hypothetical syllogisms, but he treats *in extenso* of modal syllogisms and mixed syllogisms in a manner that leads far beyond Aristotle. Although he formulates the general consequential rules in the section dealing with the Topical rules, he speaks of them in all three parts of the *Summa*, clearly implying that he considers them the basis of syllogistics.

The step that made Ockham's implication explicit was taken by Walter Burley (c. 1275–1345), a staunch adversary of Ockham in many respects but one with him in the purely formal treatment of logic. The bulk of his *De puritate artis logicae* was written after Ockham's *Summa*. As far as is known, this is the first work in the history of logic that places the consequential rules first and reduces syllogistics to a subdivision thereof.

Of the continental logicians, one of the most important was Jean Buridan (c. 1295–1366), who rewrote the *Summulae* of Petrus Hispanus, revising the theory of *suppositio* and putting it before the treatment of syllogistics, and adding a tract on demonstration.

Buridan's disciple, Albert of Saxony (c. 1316–90), rector of the University of Paris and afterward of the newly founded University of Vienna, and later archbishop of Halberstadt, integrated in his *Perutilis Logica* Burley's concept of logic (whom he often quoted in his other works), with Buridan's improvement, into the

system of William of Ockham. Thus was finally completed a system of scholastic logic which would seem to be unsurpassed by that of any other schoolman. This highly condensed and nevertheless complete logic contains six tracts. The first deals with terms; the second, with *suppositio* (adding many rules); the third, with propositions; the fourth, with consequential rules; the fifth, with fallacies; the sixth, with *Insolubilia* (insolvables, antinomies) and *obligatio*. In the first three tracts, Albert follows Ockham closely as to arrangement and content, though the second part is much better organized and considerably extended. The fourth tract, however, combines the thought of Ockham, Burley and Buridan, welding together in an ingenious system (and in this order) the general consequential rules of simple categorical propositions, of modal propositions, the consequential rules of categorical, hypothetical, modal and mixed syllogisms and the topical consequential rules. Again syllogistics is subordinated to a general theory of consequential rules.

In this work, as in all the others of the period and of subsequent periods, it is characteristic that the theory of consequential rules is treated as of primary importance. Two other dominant characteristics are a mainly extensional interpretation of the theory of *suppositio* in combination with a perfect sense for the formality of logic.

This character of the formality of logic is clearly and succinctly expressed by Albert, following Burley. The syncategorematic elements of discourse are the form; they are the skeleton of logical discourse and are clearly understood as being the constants on which the formal validity of inferences rests. The categorematic terms are understood as the material elements; variables are used for them and the rule of uniform substitution applied. Thus the inference: "A man is running, therefore an animal is running," is not valid. For the substitution made in: "If *a* is *b*, then *c* is *b*," not by *a*/man, *b*/running, *c*/animal (which would yield the true inference), but by *a*/man, *b*/running, *c*/tree, will make it a false inference. However, the inference, "If *a* is *b*, then what is *b* is *a*," is formally valid. It is also expressly stated that the position of terms or propositions belongs to the form. Hence it is not the same to say: "*Socrates ab homine differt*" ("Socrates differs from a man") and "*Socrates differt ab homine*" ("Socrates differs from man"). The former is true and the latter false. To be "formally true," "logically true" and "universally true" are interchangeable expressions. Since the syncategorematic terms as the syntactical constants of logical discourse are fixed by definition, though not by a definition of a thing (*quid rei*) but of the meaning of the term (*quid nominis*), because there is nothing corresponding to them in the object world, the famous and much misunderstood distinction between that which is true because of the expression (*de virtute sermonis*) and that which is true according to the intention of the author, calls for a rigorous analysis of ordinary speech and its reduction to exact language. In fact, it was one of the main tasks of scholastic logicians to codify laws for the complicated Latin language in order to make it a vehicle for valid inferences.

The negation of terms (yielding infinite nouns and verbs), of simple and modal categorical propositions, and of compound propositions (called hypothetical), is consistently carried through. The contradictory opposite of an expression or a sentence is always obtained by adding the sign of negation to the term itself or to the principal element of the proposition. In the latter case, this is either the verb or the modality or the main statement-connective. Lacking adequate symbolism—only term and proposition variables are used—the scholastics scrupulously insisted that the sign of negation must precede that which it is supposed to deny. Hence, a typical negation of a conditional sentence would be: "Non, si *a* est *b*, *b* est *c*."

It was partly through this device for negation and partly because of their interpretation of the "vel," the "or-conjunction," that the schoolmen, long before Augustus De Morgan, formulated the laws that bear his name. It seems that England discovered them, just as it rediscovered them; for Ockham and Burley are both in complete and perfect command of them as understood by modern logicians—that is, as applying to unanalyzed propositions.

According to Burley, the negation of: "*a et b*" ("*a*" and "*b*" being proposition variables) is "*non: a et b*," and this is equivalent to: "*non a vel non b*"; and the negation of: "*a vel b*" is "*non: a vel b*," and this is equivalent to: "*non a et non b*."

In a surprisingly extensive form, the conditional propositions and inferences between them were studied during this period and developed into a whole system. Sometimes they were united in tracts usually entitled: *De Consequentis*, of which the earliest seems to be that of Thomas (?) Sutton. Others were written by Ralph Strode and Jean Buridan—at least there is a printed text attributed to him. These tracts contain the basic theses or laws of modern propositional calculus and some of the theory of quantification, but they are not formulated as laws or theses—though sometimes used as such—but are rather formulated in a meta-language and as rules for inferences, using as names for variables or substitutions for them "antecedent" and "consequent."

The term "consequence" can be equated with "conditional proposition," though some logicians restrict it to mean logically, that is formally, valid inference. The *officialis* or operator "*s*" (if-then) is understood sometimes in the Diodorean, sometimes in the Philonian, sense; in the latter sense definitely by John of Cornwall (Pseudo-Scotus), most probably also by Ockham. Lately Ernest A. Moody devoted a special study to consequential rules and formulated more than 60 of them, corresponding to the rules given by the scholastics, and corresponding also to theses of the propositional calculus in *Principia Mathematica* and in C. I. Lewis's system of strict implication (Lewis and Langford, *Symbolic Logic*). If to these are added the modal consequences, the number goes far beyond 100, and if the syllogistic consequences of all forms are added, the number goes far beyond 1,000.

Though all the classical scholastic logicians speak of syllogistical consequences, at least one of them was aware that a syllogism in the form received from the Aristotelian commentators is not a consequence, that is, not a conditional proposition, but a juxtaposition of categorical propositions. And since as such a syllogism is neither true nor false, the denial of the conclusion of a syllogism does not infer the denial of the premisses. In order to make the rule: "From the denial of the consequent follows the denial of the antecedent" applicable to syllogisms, we must transform them into compound conditional propositions of which either the antecedent or the consequent is composed of two categorical propositions joined by the connective "and."

The theory of consequential rules deeply penetrates the entire theory of *suppositio*. The definitions of various forms and subdivisions of *suppositio* are given by formal consequences which are called "descent." The scholastics made use of four different quantifiers which are defined as follows: The universal quantifier ("every") allows the descent from a common term to copulative propositions in which the common term is particularized (*singularizatio*), and all individuals are enumerated for which the common term stands. In a similar way the particular quantifier ("some") allows the descent to a disjunctive proposition, the collective quantifier ("all") to one proposition, in which the term is singularized and its elements joined by "and"; the disjunct or confused quantifier to one categorical proposition in which the term is singularized and its elements joined by "or." For example: "Every man is an animal" is equivalent to: "This man is an animal, and that man is an animal," and so on for every individual man that is an animal. "Some man is an animal" is equivalent to: "This man is an animal or that man is an animal, etc." "All Apostles are twelve" is equivalent to: "This Apostle and that Apostle and so on for all the Apostles, are twelve." "Every man is an animal" is equivalent to: "Every man is this or that or that, etc., animal." Later scholastics also studied the relations between the various quantifiers.

During this period, and certainly beginning with Ockham, a semantical definition of truth and falsity on the basis of the theory of *suppositio* was elaborated. In its simplified form it runs: "A proposition is true if subject and predicate stand for the same or do not stand for the same as is denoted by that (affirmative or negative) proposition." Hence the proposition: "A man is white" is true if, and only if, there is a thing of which it can be

said that this is a man and this same is white.

The theory of *suppositio* also solves the problem of the so-called existential import. Hardly any of the scholastics understood a categorical universal affirmative proposition as equivalent to a conditional proposition, although they understood the latter as a consequence from the former. A scholastic universal proposition is simply invested with existential import and in order to make the *conclusio ad subalternatam* valid, it is not necessary to add an existential proposition. Later scholastic logicians added a conditional to the descent, for instance: "Every man is an animal, therefore this man, if he exists, is an animal, etc." Or they added the so-called *constantia*, that is, the proposition: "and these are all . . ." However, since the scholastics were keenly aware of the problem and moulded their theory of *suppositio* accordingly—which theory varied, for the Realists admitted the existence of universal things and the Nominalists denied it—and since many admitted the *suppositio naturalis* which was often understood as being of necessary matter, they paid attention to the problem of the conversion of propositions, and were extremely cautious about the conversion by contraposition and in the use of infinite terms (that is terms like "not-man," "not-stone").

The various and varied discussions of the logical antinomies can only be hinted at here. No more than passing mention can be made even of Raimon Lull (c. 1235–1315), whose *Ars Magica* and his method of combination (*mixtiones*) so deeply influenced Leibniz, for there is no authentic interpretation of the work of this challenging thinker who was both mystic and logician.

5. Decline of Scholastic Logic.—Toward the end of the 14th century, the decline of scholastic logic set in. The ravages of Black Death, the wars between France and England, the western schism, all acted unfavourably on the scientific culture of the late middle ages. Yet it is remarkable that especially scholastic logic managed for more than a century to maintain its high standard. Its worst enemies arose from the ranks of the Humanists who preferred classical style, poetry, and rhetoric to the rigour of the "barbaric" Latin of scholastic logic. Nevertheless it was Italy, the centre of Humanism, that produced the best logicians of the period. Paul of Venice (d. 1429), an alleged Averroist but certainly of the school of the Nominalists, composed a *Logica Magna* and *Parva*. The former is a truly monumental work, not only in regard to its size, but in the thoroughness of its formal treatment of logic as well. Paul admits only simple conversion as formally valid, applies quantification also to material *suppositio*, and has a most interesting discussion of the semantical antinomies. A more succinct and highly systematized logic, composed entirely in the form of theses, was produced by his disciple, Paulus Petrus (d. 1451).

During this time many commentaries were written, mostly on the *Summulae* of Petrus Hispanus, or on Buridan (for example, the very important commentary of Dorp). Some writers also commented on the *Logica Parva* of Paul of Venice, and on a few others of lesser importance. These commentaries are of value for historical notes. It seems that the Realists, during this period, confined their activities to writing commentaries, although toward the turn of the 15th century they began to produce original tracts, largely based on the revised order of the *Summulae* of Petrus Hispanus. Of the Scotists, mention should be made of the commentaries of Johannes Magistri (c. 1400), of Johannes de Monte (c. 1450) and especially of Petrus Tartaretus (rector at Paris, 1490–1495) who also composed an excellent little tract on the Descent. Of the Thomistic tradition, the logic of St. Vincent Ferrer (written 1372) merits attention, and the more extensive work of Chrysostom Javellus (d. 1538), both of which continue the realist Terminist logic.

Under the impact of the Reformation and the new philosophy, the so-called Nominalistic logic, and in general the extremely formalized logic of the 14th and 15th centuries, disappeared from the scene. With the Counter Reformation, toward the end of the 16th century, a kind of scholastic renaissance took place, but it disregarded much of the former achievement, going back primarily to the philosophy of St. Thomas and Duns Scotus. Johannes Sancto Thoma (1589–1644) composed a logical tract that be-

drawn some attention from modern scholars; and the works of Silvester Maurus, S.J. (1619-87), and Bartholomew Mastrius, O.F.M. Conv. (1602-73), have also won the notice of recent writers.

The 17th century saw the complete disintegration of scholastic logic. Subsequent degeneration was so rapid that by the middle of the 18th century it was dead to all practical purposes.

See also the separate articles on many of the logicians mentioned in this section. (PH. B.)

IV. MODERN LOGIC

In this section we outline the development of deductive logic from the 16th to the middle of the 20th century. The history of inductive logic is treated in the articles INDUCTION; PROBABILITY; and SCIENTIFIC METHOD.

1. **Ramée.**—Pierre de la Ramée, or Petrus Ramus, whose anti-Aristotelian position was widely influential, is perhaps the first of the post-scholastic logicians who deserves mention here. One of the earliest noteworthy works on logic in a modern language is his *Dialectique* of 1555, though other works are in the traditional Latin. His *Dialecticæ Libri Duo* of 1556, long used as standard (John Milton's *Artis Logicæ Plenior Institutio*, 1672, is, e.g., but a revised edition of it), has a much modified and abbreviated version of the older logic, omitting the immediate inferences altogether and greatly simplifying the rules of the categorical syllogism. In an altered classification into moods or kinds, a special place is provided for syllogisms having two singular premisses, including not only the two moods of the expository syllogism (see LOGIC) but inferences involving a singular predicate, such as: Octavius is heir of Caesar, I am Octavius, therefore I am heir of Caesar; Judas that wrote the Epistle was the brother of James, Judas Iscariot was not the brother of James, therefore Judas Iscariot was not the Judas that wrote the Epistle.

Propositions with singular predicates had been treated by Ockham, Pseudo-Scotus, and other scholastics—as well as the expository syllogism, by some as confined to the third figure, so that the singular middle term occurs only as subject, but by others as admitting moods also in other figures. And indeed Pseudo-Scotus already maintained that syllogisms with singular premisses should be brought into the Aristotelian form by rereading in the following way: Everything which is Octavius is heir of Caesar, everything which is I is Octavius, therefore everything which is I is heir of Caesar. The Ramistic treatment of these singular inferences as non-Aristotelian was later countered on similar grounds by Thomas Spencer (*The Art of Logick delivered in the precepts of Aristotle and Ramus*, London, 1628) and, more sharply, by the mathematician John Wallis (q.v.) in his Cambridge thesis of 1639, published in 1643, and in his *Institutio Logicæ* of 1687. Wallis reached the conclusion that singular propositions are to be assimilated to universal propositions for purposes of the syllogism, on the ground that the predicate of a singular proposition and of a universal proposition are alike predicated of all, of the whole rather than a part of the subject. Following, not necessarily Wallis, but earlier writers generally, the authors of the Port-Royal Logic (see below) give a similar account of singular propositions, so that it is said that all propositions can be reduced to the four forms *A, E, I, O*. And this remained the generally accepted doctrine until the traditional point of view was superseded by the development of modern logic in the 19th and 20th centuries.

2. **Jungius.**—Joachim Jungius, in his *Logica Hamburgensis* of 1638, brought forward and discussed a number of forms of inference that are not reducible to the traditional immediate inferences and syllogisms. Relations especially are involved in these, and if widespread attention and study had been given to the matter, the logic of relations might have been developed two centuries in advance of the actual event. But Jungius remained without important influence, except upon Leibniz, and his contributions to logic were ignored by his successors or (e.g., by Wallis) dismissed as reducible to the traditional doctrine.

One of these forms of inference which Jungius considers is that of the so-called *oblique inferences*, which had already been treated by Aristotle. An example is: The square of an even number is

even, 6 is an even number, therefore the square of 6 is even. The significance of this, as it appeared in the light of much later developments, may be seen by attempting to reduce to traditional syllogistic form as follows: Every even number has an even number as square, 6 is an even number, therefore 6 has an even number as square. In this way the conclusion has 6 as its subject. And if we wish then to infer, in another syllogism, that 36 is the square of 6 and therefore 36 is even, we must first transform the conclusion so that it will have as its subject, the square of 6. The inference which is missing from the traditional catalogue of forms is the immediate inference (if we wish to call it that) from the proposition, 6 has an even number as square, to the proposition, the square of 6 is an even number.

To make the issue clearer we may put the inferences into modern notation, using $e(x)$ to mean that x is even, and $s(x, y)$ to mean that the square of x is y . The first inference is then from the premisses $e(x) \supset s(x, y) \supset e(y)$ and $e(6)$ to the conclusion $s(6, y) \supset e(y)$, and the second inference then uses the additional premiss $s(6, 36)$ to draw the conclusion $e(36)$. Relational inferences of this sort—here illustrated in a case so simple as to be almost trivial—are as a matter of fact essential to nearly all important mathematical reasoning.

Other examples of Jungian relational inferences are the following. A circle is a figure, therefore who draws a circle draws a figure: $c(x) \supset f(x)$, therefore $c(x) \wedge d(x, y) \supset f(x) \wedge d(x, y)$. A reptile is an animal, therefore Who created every animal created every reptile: $r(x) \supset a(x)$, therefore $a(x) \supset C(x, y) \supset r(x) \supset C(x, y)$. David is the father of Solomon, therefore Solomon is the son of David; i.e., upon supplying a tacit premiss, $f(x, y) \supset_{sy} s(y, x)$, $f(S, D)$, therefore $s(D, S)$. (This last had been considered also by Galen.)

3. **Geulincx.**—Arnold Geulincx published in 1662 *Logica Fundamentis Suis, a quibus hactenus collapsa fuerat, Restituta*. Though the title indicates the author's intention to restore neglected fundamentals, this is not just a reproduction of the scholastic logic but an original work. Following are some points of special interest. The doctrine of *suppositio*, largely ignored by other logicians of the period, is here reproduced in altered terminology and with some alteration in content; the possibility of using the same term with different kinds of *suppositio* is treated as being (with a suitable exception to allow for syllogistic inference) a form of equivocity, and the device is mentioned in particular of underlining in manuscript or using a distinct style of type in print, to distinguish "grammatical" (i.e., material) *suppositio* and "logical" (i.e., simple) *suppositio* from others. It is argued that negation may be applied only to propositions, and not to terms. Detailed rules (not new except in viewpoint) are given for the reduction of negations, including what are now known as the De Morgan laws of the propositional calculus, the law of double negation, and such reductions as that of *not all not* to *some*, i.e., of $\sim(x) \sim$ to $(\exists x)$. Treatment of the categorical syllogism is brief but adequate, and is supplemented by mention of the inference known as the anti-syllogism (example: Peter is not an animal, therefore either Peter is not a man or some man is not an animal). What would now be called valid inferences of the propositional calculus are especially well handled, in spite of the handicap of doing it entirely in words, without the aid of special symbols other than the use of capital letters to stand for propositions. Disjunction is explained clearly as inclusive, and *modus ponendo tollens* is rejected (in contrast with the uncritical acceptance of this inference by Ramus and by the Port-Royal Logic). The copulative syllogism (see LOGIC) is treated by use of the appropriate De Morgan law to reduce it to *modus tollendo ponens*. No reduction of the negation is given in the case of conditional propositions, but negations of such propositions are considered, and the following inferences are allowed: from $\sim . A \supset B$ to $\sim . \sim B \supset \sim A$; from $B \supset C$ and $\sim . A \supset C$ to $\sim . A \supset B$; from $A \supset B$ and $\sim . A \supset C$ to $\sim . B \supset C$; from $A \sim B$ to $\sim . A \supset B$.

Geulincx considers at one point the inference: Every white man is white, every white man is a man, therefore some man is white. He notes that the premisses are necessary, but the conclusion contingent. And he rejects the inference on the ground that the

word "white" is used equivocally—in the conclusion to refer to the present time, and in the premisses absolutely, *i.e.*, without reference to time—so that the syllogism has four terms. The weakness of this is that there are still only three terms in the premisses, and on the traditional doctrine a conclusion should follow in Darapti. But it remained for Leibniz some decades later to give more serious consideration to the problem of existential import.

4. Port-Royal Logic.—Port-Royal Logic or *La Logique ou l'Art de Penser*, the original title, was written by Antoine Arnauld and Pierre Nicole, possibly with the collaboration of some others, and was first published in 1662. It was, like Ramus, long and widely used (both Latin and English translations appeared in England) and though the authors follow Ramus in the fourfold division of logic into idea, judgment, reasoning and method, they restore the Aristotelian-scholastic treatment of opposition, conversion and the categorical syllogism.

An important original contribution of the Port-Royal Logic is the distinction between *comprehension* and *extension*—of ideas, as the authors say—or of concepts, or of terms, as is more usually said by later writers. The comprehension of a concept consists namely of all those attributes which are contained in it and cannot be removed from it without destroying it—as, *e.g.*, the authors say, the idea (concept) of a triangle contains extension, figure, three sides, three angles, the equality of the sum of these three angles to two right angles, etc. And the extension of a concept consists of the subjects to which it extends, or of what were traditionally called the inferiors of a general term—so that, *e.g.*, the extension of the concept of a triangle consists of all the different species of triangles: isosceles, right, obtuse, etc. This distinction was widely adopted by later writers and became a standard part of the traditional logic. Along with Mill's connotation and denotation of names it may be thought of as a forerunner of Frege's distinction of sense and denotation (*see SEMANTICS IN LOGIC; CONNOTATION; and DENOTATION*).

The Port-Royal Logic also contains the first publication of the ideas of Blaise Pascal (*q.v.*) about the nature of definition. Namely it was Pascal who first observed that every demonstrative science must begin, not only with unproved propositions (*see AXIOM, and POSTULATE*) but also with undefined terms, or *termes primitifs* as they are called in the Port-Royal Logic. Pascal also restricts definitions in mathematics to nominal definitions, *définitions de nom*, which consist merely in the giving of a name to something which has been clearly designated in terms completely known; the use and purpose of such definitions is the abbreviation of discourse; they are entirely free, and never subject to being contradicted; and, as Pascal wrote in a letter to Le Pailleur, one may equally well define something impossible as something actual. These ideas were taken up by the authors of the Port-Royal Logic, who lay great emphasis on the need for careful definition as a means of avoiding confusion of thought. However they retain also the notion of a real definition, or *définition de chose*, as a proposition which explains the nature of a thing by means of its essential attributes, and which is therefore capable of being confirmed or disputed. And the idea, which arose much later, that primitive terms and axioms (or postulates) are, like nominal definitions, arbitrary, is not to be found in the Port-Royal Logic; on the contrary the authors demand, following Pascal, that primitive terms shall be completely known, and axioms completely evident.

5. Saccheri.—Giovanni Girolamo Saccheri's *Logica Demonstrativa* of 1697 and 1701 also requires mention, though the author is (deservedly) better known for the partial anticipation of non-Euclidean geometry in his *Euclides Vindictus* of 1733 (*see GEOMETRY, NON-EUCLIDEAN*). The *Logica* provides a treatment of the traditional logic in the form of a series of demonstrations based on postulates and definitions, in the manner of works on geometry. Two points are emphasized which afterward played an important role in the *Euclides Vindictus*, namely: (1) the law of Clavius (*see LOGIC*) and the associated method of proving a proposition by showing it to be a consequence of its own negation; and (2) the distinction between nominal definitions and real definitions, on the basis that the former merely state the meaning of a term, whereas

the latter carry also the assertion of existence.

(1) is the *consequentia mirabilis* of 17th-century scholastic writers. Geronimo Cardano (*q.v.*) writes in his *De Proportionibus* of the striking character of this method of proof, which he thought to be his own discovery. Knowledge of the method came to Saccheri through Christopher Clavius, by whose name the law is sometimes known, and who, in commentaries on Euclid and on Theodosius, points to its use by Euclid, by Theodosius, and by Cardano. But Saccheri was the first to exploit this method of proof systematically—in his *Logica* and in *Euclides Vindictus*.

Significant in (2) is that definitions are always of terminology, and real definitions are distinguished from nominal by the added demonstration or assumption of existence. Otherwise Saccheri had been anticipated by Pascal and in the Port-Royal Logic, in regard to the nature of nominal definitions and the fallacy of misusing a nominal definition in the role of a real definition. (But Saccheri, in his Latin terminology and in his notion of nominal definition, is evidently following Ockham and other scholastics rather than Pascal.)

6. Leibniz.—Gottfried Wilhelm von Leibniz (*q.v.*; Leibniz brought forward already in a work published in his youth (*Dissertatio de Arte Combinatoria*, 1666) the project of constructing a universal exact system of notation, a symbolic language, in which all concepts would be so analyzed into their ultimate constituents, by the notation itself, that it would be the means for a fundamental knowledge of all things. This project of a *lingua characteristica universalis* was partly based on the ideas of Lull, to whom Leibniz refers. Leibniz continued to advocate it throughout his life, later adding as an important part the project of a *calculus ratiocinator* or calculus of reasoning. And though the total program of Leibniz, as just described, is no doubt not even theoretically fulfillable, the *calculus ratiocinator* remains an important forerunner of the logicistic method in logic.

Leibniz's contributions to logic remained largely unpublished during his lifetime. The most important waited publication much more than a century. But Raspe's *Oeuvres Philosophiques de Leibniz*, published in 1765, contains a purely descriptive paper about the *lingua characteristica universalis*, a paper which treats the difficulty concerning existential import, and the *Nouveaux Essais sur l'Entendement Humain*.

In the paper on existential import, Leibniz is led to hold that all four of the categorical forms *A, E, I, O* are to be understood on the basis of a tacit presupposition that the terms which enter are existent (are not empty). This Leibnizian solution of the difficulty has often been adopted since; and if class variables are used to formulate the traditional logic of categorical propositions, the solution may be put in the form of restricting the range of values of the variables to *non-empty* classes. There is, however, the objection that this seriously reduces the applicability of the traditional logic, as it may be impracticable to ascertain in advance that all terms are existent, and syllogistic reasoning may serve a substantial purpose even in cases in which it is possible or probable that some of the terms are empty.

In a passage in the *Nouveaux Essais*, Leibniz discusses the relational inferences of Jungius, correctly remarking that they cannot be reduced to any traditional syllogism except by a *changement des termes* which renders the total process of inference asyllogistic (*see above*).

The same work also contains a statement of the law of identity in the form, "*A is A*," or "*All A is A*." This law must not be credited exclusively to Leibniz—since Leibniz refers to its use by Ramus to treat the Aristotelian conversions as special cases of categorical syllogisms—and since indeed this possibility was known in the 13th century, and there is mention already by Boëthius of what John Locke (in 1690) called "identical propositions." But it was Leibniz who first ascribed to the law of identity a special status as a "primitive truth of reason."

In many of his works Leibniz seems to overestimate the importance of one or both of the laws of contradiction and identity. In the *Nouveaux Essais* Leibniz avoids saying that these laws are alone a sufficient basis for the whole of logic, and even may be thought to imply the contrary. But elsewhere he is less cautious

especially in writings that were not intended for publication. Thus in *Réflexions sur l'Essai de l'Entendement Humain de Mr. Locke* (published with Locke's letters in 1708) and in the reply to the first letter of S. Clarke (published in 1717 after Leibniz's death) it is said that the law of contradiction, so stated as to include the law of identity, suffices to demonstrate either all truths independent of experience or all principles of mathematics. It would seem that Leibniz at times really hoped that all necessary truths might be demonstrably reduced to these very simple ones—though indeed with the aid of certain principles of inference, especially the syllogism in Barbara (*cf.* the letter quoted by J. E. Erdmann, vol. 1, p. 81). But some of his successors made the idea into an unsupported and almost meaningless item of doctrine—see THOUGHT, LAWS OF.

Leibniz's actual attempts at the construction of a *calculus ratiocinator* were made in the period from 1679 to 1690 and are published, some in Erdmann's *Opera Philosophica* (vol. 1, 1840) and C. I. Gerhardt's *Philosophische Schriften* (vol. 7, 1890), the remainder in L. A. Couturat's *Opusculs et Fragments Inédits* (1903). These show beginnings from which the modern treatment of logic might well have developed. But their content remained unknown for 150 years, and historically only the generalities of Leibniz's program exerted any influence.

In the century following Leibniz there were many attempts at a logical calculus, of which the most widely known and discussed were those of Gottfried Ploucquet (in 1763) and of Johann Heinrich Lambert (*q.v.*) (in 1767, and in a number of fragments published in *Lamberti Logische und Philosophische Abhandlungen*, vol. 1, 1782). Lambert's are noteworthy as containing some beginnings of a logic of relations. But none of the attempts produced a satisfactory calculus, and the main trend of opinion was against this direction.

7. **Euler.**—Leonhard Euler (*q.v.*), in his *Lettres à une princesse d'Allemagne* (vol. 2, 1770), illustrated his treatment of the categorical syllogism by using the interiors of three circles to represent the minor term, the middle term and the major term. Thus $s(x) \supset m(x)$ is pictured by showing the circle for s entirely within that for m , and $s(x) \supset \sim m(x)$ by showing the two circles as non-overlapping, etc. This method of visually checking the validity of syllogisms was brought into general use through its adoption by Euler, and came to be known as the *Euler diagram*, though the device did not originate with Euler. Such circle diagrams had been employed in special cases by Johann Christoph Sturm (*Universalia Euclidea*, 1661); and they were used by Leibniz to treat the categorical syllogisms systematically, in a fragment not published until 1903; but their first systematic use for this purpose in a published treatise seems to have been by Johann Christian Lange (*Nucleus Logice Weisianaë*, 1712).

8. **Kant.**—Immanuel Kant (*q.v.*) contributed little to logic. Indeed it was his opinion that logic had made no important step either forward or backward since Aristotle, and seemed to all appearance to be finished and complete (*Kritik der reinen Vernunft*, preface to 2nd ed., 1787). But his influence was great because of his reputation in other fields. In particular the general acceptance of the term, *analytic*, for propositions that are true on logical grounds alone is traceable to Kant, although Kant's own definition of the term would restrict it to a narrow subclass of such propositions, and although the term, *analytic*, and its opposite, *synthetic*, had been used already by Christian August Crusius in 1747. The now familiar contention that "existence is not a predicate" is due to Kant, who used it (*op. cit.*) as an objection against the so-called ontological proof of the existence of God; but a satisfactory positive analysis of the notion of existence had to await the introduction of the quantifiers by Frege and Mitchell.

9. **Hegel.**—Georg Wilhelm Friedrich Hegel (*q.v.*), in *Wissenschaft der Logik* (1812–16), denounces the Leibnizian project of a universal symbolic language as shallow and senseless, and singles out for special attack Ploucquet's recommendation of his calculus as making possible the mechanical performance of logical inference without danger of error if the rules of the calculus are followed. Hegel is similarly critical of the Euler diagrams, and even of the long-established formal treatment of the syllogism as it appeared

in the traditional logic of his day. It is not without some justice that he reproaches the latter with being in an ossified and contemptible state. But Hegel represents, as an extreme example, the tendency which long prevailed to hold logic itself in low esteem and to devote the greater part of a work on logic to other subjects, especially to topics in epistemology and metaphysics that bear upon the traditional logic or are suggested by it.

10. **Bolzano.**—Bernard Bolzano's *Wissenschaftslehre* of 1837 contains many original contributions of which the importance was long overlooked, and its proper place in the history of logic came to be seen only in the light of much later developments. In this brief account we confine attention to a single point, Bolzano's treatment of the notion of analyticity.

Bolzano introduces notions of analyticity in a *wider* and in a *narrower* sense; but of these only the latter is free from serious objection, and will be described here. It will be convenient to state Bolzano's definition with respect to a formalized language, though it must be remembered that Bolzano did not have this means available, and such restatement of his definition gives it an appearance of greater rigour than was possible for Bolzano himself. We may take this language to be the set theory of Zermelo (*see* LOGIC), with a large number of individual constants added, corresponding to the words of various kinds that appear in an English dictionary, so that the language becomes (theoretically) usable for purposes of ordinary discourse as well as for expressing propositions of pure logic and of mathematics. Also we state the definition as for an *analytically true sentence*, although Bolzano deals rather with the proposition ("Satz an sich") expressed by a sentence; and we employ the terminology explained in the article LOGIC, instead of Bolzano's own. From any sentence let a corresponding propositional form be obtained by replacing every extra-logical constant (Bolzano says extra-logical concept) by a variable, two or more occurrences of the same constant being replaced always by the same variable, and different constants by different variables. A sentence is then analytically true (in the narrower sense) if either: (1) the corresponding propositional form is true for all values of the variables; or (2) the sentence can be reduced to one satisfying condition (1), by a series of steps which consist in replacing an occurrence of an individual constant by a synonymous constant or a well-formed part by a synonymous well-formed part.

This definition is not without its difficulties. In particular no explication is offered of the notions of synonymy and of being true for all values of the variables (or satisfied by all values of the variables—*see* SEMANTICS IN LOGIC), but these notions are taken for granted; indeed the notion of synonymy is not explicitly present at all, but is implicit in the treatment of propositions rather than sentences, and its role is indicated only by some examples. Bolzano himself calls attention to the possibility of dispute as to which constants, or concepts, shall be recognized as logical and which as extra-logical (though in the case of the particular language which we have here selected for the purpose of illustration, it might be possible so to control the vocabulary of added individual constants that all constants but Λ and ϵ would be clearly extra-logical). In spite of such difficulties, Bolzano must be credited with having proposed the first definition of a distinction between analytic and synthetic propositions that deserves serious consideration from the point of view of its logical adequacy.

A minor point is that Bolzano completed Kant's classification of propositions into analytic (analytically true) and synthetic by adding a third category of the analytically false.

11. **Mill.**—John Stuart Mill's *A System of Logic, Ratiocinative and Inductive* (1843) is remembered for its contributions to inductive logic, which are outside the scope of this article, and for its introduction of the distinction of CONNOTATION and DENOTATION, which is treated in the articles of those titles.

12. **Algebra of Logic.**—The algebra of logic had its beginning in publications of George Boole (*q.v.*) and Augustus De Morgan (*q.v.*) which appeared simultaneously in 1847. There are two main divisions.—The algebra of classes has three basic operations, the logical sum (or union) $F + G$ of two classes F and G , the

logical product (or intersection) FG of F and G , and the complement F' of a class F . In the notation introduced in the article *Logic*, $F + G$ may be explained as meaning $\lambda x[F(x) \vee G(x)]$, FG as meaning $\lambda x[F(x)G(x)]$, and F' as meaning $\lambda x \sim F(x)$. The notation \circ was used for the empty class; and 1 for the universal class, i.e., the class which coincides with the domain of individuals so that all individuals belong to it. And equations and inequalities were written, such as $G + H = F' + G'$ to mean that the logical sum of G and H is the same as the logical sum of the complements of F and G , or $FG \neq \circ$ to mean that the logical product of F and G is not empty, or $F \leq G$ to mean that F is contained in G in the sense that all individuals belonging to F belong also to G .—The algebra of relations has six basic operations, the logical sum $F + G$ of two relations F and G , the logical product FG , the contrary F' (or $-F$), the relative sum $F \dot{+} G$, the relative product $F \dot{G}$, and the converse F . These may be explained as meaning respectively $\lambda x \lambda y [F(x, y) \vee G(x, y)]$, $\lambda x \lambda y [F(x, y)G(x, y)]$, $\lambda x \lambda y \sim F(x, y)$, $\lambda x \lambda y (z) [F(x, z) \vee G(z, y)]$, $\lambda x \lambda y (z) [F(x, z)G(z, y)]$, $\lambda x \lambda y F(y, x)$. The notation \circ was used for the empty relation, 1 for the universal relation, \circ' for the relation of diversity (which holds between x and y if and only if x and y are different individuals), $1'$ for the relation of identity. And again equations and inequalities may be written.

The three basic operations of the algebra of classes, and the six basic operations of the algebra of relations, obey laws which are of much the same kind as familiar laws of the algebra of numbers (and in part coincide with them). By using these a formal algebra or calculus of classes may be set up, and an algebra of relations. These were the first successful calculi of logic. As treated by 19th-century writers, neither is yet a logistic system in the sense of modern logic, but a calculus in a less rigorous sense.

Various notations were used by different writers. And when the two algebras were incorporated into *Principia Mathematica* (see below) as parts of the logistic system of that work, the authors, partly following Giuseppe Peano, changed the old notations completely. In the algebra of classes the logical sum, logical product, and complement are expressed by $F \cup G$, $F \cap G$, and $-F$ respectively, and the notations \circ , 1 , \leq are changed to Δ , ∇ , \subset respectively. In the algebra of relations the same notations are used with a dot added, as $F \dot{\cup} G$, etc.

The method of Boole, in 1847 and in 1854, is not an algebra of classes in the sense described above, but an application of ordinary numerical algebra to the logic of classes—as is possible if the logical sum of F and G is written as $F + G - FG$, and the complement of F is written as $1 - F$. Yet Boole was able to obtain in this way the essential results of the algebra of classes, and indeed worked them out more fully than De Morgan. In De Morgan's *Formal Logic* of 1847 are, however, some beginnings of the algebra of classes in the more proper sense, including in particular the De Morgan laws $(FG)' = F' + G'$, $(F + G)' = F'G'$ (it was only later that De Morgan's name came to be applied also to the analogous laws of the propositional calculus). From these beginnings the algebra of classes developed into its classical form through contributions by William Stanley Jevons (*q.v.*) (*Pure Logic*, 1864, and later works), Charles Sanders Peirce (in a series of papers beginning in 1867), Ernst Schroeder (*Der Operationskreis des Logikkalküls*, 1877), John Venn (*Symbolic Logic*, 1881), and Platon Poretsky (in papers published in the period from 1884 to 1908).

The algebra of relations had its beginnings in publications by De Morgan (*Syllabus of a Proposed System of Logic*, 1860, and a paper in the *Transactions of the Cambridge Philosophical Society*, vol. 10, 1864) and received its major development at the hands of Peirce (in papers beginning in 1870) and Schroeder (in *Algebra der Logik*, vol. 3, 1895).

The standard reference work on the algebra of logic is Schroeder's three-volume *Algebra der Logik* (1890–1905). However, Schroeder's axiomatic basis of the algebra is deficient, and should be replaced, in the case of the algebra of classes by E. V. Huntington's (*Transactions of the American Mathematical Society*, vol. 5, pp. 288–309, 1904), and in the case of the algebra of relations by Tarski's (*The Journal of Symbolic Logic*, vol. 6, pp. 73–89, 1941).

There is a sense in which the algebra of logic has also a third division, the algebra of propositions, though not always clearly distinguished from the algebra of classes. Boole had already considered the alternative of interpreting the variables of his algebra as propositional variables instead of class variables. But the first true calculus of propositions appears in papers of Hugh MacColl, beginning in 1877; and in particular it was MacColl who rediscovered the so-called De Morgan laws of the propositional calculus (known already to the scholastics). The second volume of Schroeder's *Algebra* has a combined algebra of classes and propositions.

13. Peirce.—Charles Sanders Peirce (*q.v.*), besides the matters already mentioned, has the credit of having taken the first steps in many things which afterward became important in the development of logic. These include the first definition of the notion of simple order (1881); the first treatment of the propositional calculus as a calculus of two truth-values (1885); the definition of \sup (1885) which is given above in the article *Logic* (though this had been partly anticipated by Leibniz's informal definition, "Things are identical of which one can be substituted for the other with preservation of truth"); and the definition of finiteness (1885) which would be expressed in modern notation as follows: G is a finite class if $(F) \cdot F(x, y)F(x, z) \supset_{\text{sym}} y = z \supset \cdot F(x, z)F(y, z) \supset_{\text{sym}} x = y \supset \cdot G(x) \supset_{\text{sym}} (\exists z)[G(z)F(x, z)] \supset \cdot G(x) \supset_{\text{sym}} (\exists x)[G(x)F(x, z)]$. Peirce also initiated in 1881 the method of treating the foundations of arithmetic which was afterward developed by Julius (Wilhelm Richard) Dedekind (*Was sind und was sollen die Zahlen?*, 1888) and Giuseppe Peano (*Arithmetices Principia*, 1889).

The *Insolubilia* were discussed by Peirce (1869, 1901) with direct reference to the medieval sources. It is quite possibly through Peirce that the Liar first came to the attention of Bertrand Russell, but it required the independent discovery of Richard's antinomy (see below) to make clear the importance of what are now known as the *semantical* antinomies or paradoxes.

In a paper of 1880, in treating the categorical syllogism, Peirce says that traditionally the affirmative (categorical) propositions imply that their subjects are existent, while the negative ones do not; but he will assume rather that particular propositions imply the subjects existent, universal propositions not. Indeed this change of the convention about existential import is strongly indicated from the point of view of the algebra of classes; it was implicit in a short note published by Arthur Cayley in 1871, but was first made explicit from this point of view by Peirce, and by Venn in 1881. It is true that under the changed convention, certain traditional inferences (e.g., conversion *per accidens*, syllogism in Darapti) require an added existential premiss to validate them. But the convention which Peirce describes as the older one also renders some of the immediate inferences invalid without an added existential premiss, those namely (including contraposition) that involve obversion of a negative proposition.

14. Brentano.—Franz Brentano, in his *Psychologie vom Empirischen Standpunkte* of 1874, made it a part of his psychology of judgment that every proposition can be reduced to an (affirmative or negative) existential proposition, so that, e.g., "Some man is ill" and "All men are mortal" are said to have the same sense as "An ill man is" and "An immortal man is not" respectively. In modern notation the four categorical forms A, E, I, O thus become $\sim(\exists x) \cdot s(x) \sim P(x)$, $\sim(\exists x) \cdot s(x) P(x)$, $(\exists x) \cdot s(x) P(x)$, $(\exists x) \cdot s(x) \sim P(x)$. Hence quite independently of the algebra of logic (to which he was opposed) Brentano arrived at the same doctrine of existential import which was later introduced by Peirce as described above, and at the same modification of the traditional logic, including rejection of the syllogisms in Darapti, etc. But Brentano seems to defend his own revision of the traditional rules as the only right one, whereas Peirce sees more clearly that it is a matter of choosing the convention under which the formal treatment of logic can proceed most efficiently.

An exposition of Brentano's logical innovations was published by J. P. N. Land in the first volume of the British periodical *Mind* in 1876. And a detailed treatment of immediate inference and the syllogism from Brentano's point of view is in Franz

Hillebrand's *Die Neuen Theorien der Kategorischen Schlüsse* of 1891.

15. Frege.—Gottlob Frege is the founder of modern logic in a sense in which neither Leibniz nor De Morgan and Boole can be so considered, and as such is unquestionably the greatest logician of modern times. The essential steps in the introduction of the logistic method were taken in his *Begriffsschrift* of 1879. In the same work there appear for the first time the propositional calculus in its modern (logistic) form, the notion of a propositional function, the use of quantifiers and the logical analysis of proof by mathematical induction in terms of the notion of a hereditary property—or hereditary class, as we shall here prefer to say.

This last was important in Frege's definition of an inductive cardinal number, and thus provided the basis for the derivation of arithmetic from logic which was described and defended in his *Grundlagen der Arithmetik* (1884) and carried through rigorously in the first volume of his *Grundgesetze der Arithmetik* (1893). To state the definition in the slightly modified form in which it was later used by A. N. Whitehead and Bertrand Russell in *Principia Mathematica*, let us call two classes G and H similar if there is a one-to-one correspondence between them, i.e., if $(\exists F) \cdot F(x, y)F(x, z) \supset_{\text{ex}} y = z \cdot F(x, z)F(y, z) \supset_{\text{ex}} x = y \cdot G(x) \supset (\exists z)[H(z)F(x, z)] \cdot H(z) \supset (\exists x)[G(x)F(x, z)]$. As the cardinal number of a class G , we might think to take the concept, or property, of similarity to G . But if a property is understood (as usual) in intension, this has the defect that the cardinal numbers of two different but similar classes will not be actually identical. Hence we are led to take the corresponding extension, i.e., to define the cardinal number of G as the class of classes which are similar to G . The cardinal number of H is successor of the cardinal number of G if, for some class H_1 similar to H , $(\exists y) \cdot H_1(y) \cdot G(x) \equiv_x H_1(x) \sim x = y$; a class of cardinal numbers is hereditary if all successors of cardinal numbers belonging to it also belong to it; the cardinal number of the empty class Λ is the number 0; and the inductive cardinal numbers (the non-negative integers) are those which belong to every hereditary class to which 0 belongs.

From an antinomy due to Georg Cantor, concerning the question of the greatest (infinite) cardinal number, Russell extracted the simpler antinomy which is now known by Russell's name (see ANTINOMY), and communicated it to Frege in 1902. As the antinomy can be put into the form of a demonstration of contradictory theorems from Frege's logical axioms, Frege felt that one of the foundations of his construction had been shattered. Indeed it must have seemed to Frege and his contemporaries that his great work was a failure. For although Frege's axioms can be amended to remove the inconsistency—and Frege himself made some suggestions in this direction in the Appendix to the second volume of his *Grundgesetze der Arithmetik* (1903)—it must then seem that the axioms have been artificially designed for a purpose, and it is less easy to maintain that they have been taken once for all from a realm of eternal truth. It is only in the perspective of time that we are able to see that Frege's positive contributions far outweigh the inconsistency of the particular system in which they were embodied.

Independently of Frege, the use of quantifiers was suggested also by O. H. Mitchell, to whom the idea is credited by Peirce in his paper of 1885.

Other important contributions of Frege are the distinction of *sense* and *denotation* (see SEMANTICS IN LOGIC), and the device of systematically employing quotation marks to distinguish the mention of a term, expression or symbol from its use. The latter distinction is in a sense obvious, and was already recognized among the medieval distinctions of *suppositiones*; yet failure to observe it has been the source of much confusion, in Frege's day and since.

16. Venn.—John Venn, besides contributions already mentioned, introduced in 1880 the *Venn diagram*. This is a modification of the Euler diagram (see above) in which the three circles are so drawn as to overlap in all possible ways, thus dividing their plane into eight regions; and to represent the given premisses, some of

these regions are shaded as a sign that the classes they stand for are known to be empty, and others are marked with a star as a sign of non-emptiness. If an inference is to be dealt with (not necessarily syllogistic) that involves n basic classes, $n > 3$, the corresponding regions may be drawn as ellipses or other more complicated shape, instead of circles, and so placed as to divide their plane into 2^n regions; and then the same process of shading and starring is followed.

17. Peano.—Giuseppe Peano is important for his influence on Russell, and for his contribution in devising a scheme of logical notation which is more convenient than those of Peirce, Schroeder and Frege, and much of which (through its adoption by Russell) is still in use. Peano's postulates for arithmetic (see POSTULATE) are due to Dedekind in all but the point of view of taking them as postulates. His *Formulaire de mathématiques*, written with the aid of collaborators and published in five "volumes" (or editions) from 1894 to 1908, is intended as a compendium of mathematics, developed from its postulational beginnings with the aid of Peano's logical notation. His treatment of logic had begun to go beyond the algebra of logic but he did not yet have the logistic method.

18. Burali-Forti.—Cesare Burali-Forti stumbled upon the antinomy which now bears his name (see ANTINOMY), in a paper of 1897 in which he seems to have been not aware that he had revealed antinomy at all.

This antinomy and that of the greatest cardinal number were known already to Cantor but had not been published, and it was through Burali-Forti's paper that there first came to general attention the threat to the foundations of mathematics that is constituted by the antinomies.

19. Russell.—Bertrand Russell (*q.v.*) adopted Frege's thesis that arithmetic is a branch of logic, in the sense that all the terms of arithmetic can be defined with the aid of logical terms only (see the brief statement above as to how, in part, this is to be done), and all the theorems of arithmetic can be proved from logical axioms only. And the same thesis was extended by Russell to the whole of mathematics—a doctrine which later came to be known as *logicism*. The project of carrying this out is the subject of Russell's *The Principles of Mathematics* (1903). The theory of types as a means of avoiding the inconsistency of such a system as Frege's, though the idea of it was discussed in the *Principles*, was first put into satisfactory form by Russell in a paper of 1908, and on this basis the detailed logicistic development of a large part of mathematics is in the three volumes of Whitehead and Russell's *Principia Mathematica* (1910-13). Thus Whitehead and Russell succeeded where Frege failed. But the theory of types compels the use of the axiom of infinity—which plays no role in Frege's work—and some have objected that this is not properly an axiom of logic.

The type theory of *Principia* is the so-called *ramified theory of types* (concerning which see MATHEMATICS, FOUNDATIONS OF). The reduction of this to the simple theory of types was mentioned by Leon Chwistek in 1921; independently of Chwistek, it was advocated more seriously by F. P. Ramsey in 1926, and thence came into general use through its adoption by Rudolf Carnap (*Abriss der Logistik*, 1929) and Kurt Gödel (1931).

Another major contribution of Russell is the device (1905) by which descriptive phrases such as "the 32nd president of the U.S.A." may be eliminated if desired (see SEMANTICS IN LOGIC). A technical improvement of Russell's device, important especially when it is employed in a formalized language, was introduced by W. V. Quine in 1940.

20. Zermelo.—Ernst Zermelo stated the axiom of choice in 1904—the use of which in mathematical reasoning had previously been tacit and unrecognized. The first formulation of axioms for set theory was by Zermelo in 1908. Zermelo's axioms involve, however, an unexplained notion of a "definite property." Different proposals for overcoming this difficulty were made by A. A. Fraenkel and Thoralf Skolem in 1922 and 1923, of which Skolem's has the advantage that it leads more directly to logistic formalization of Zermelo's verbally stated axioms. The axioms of set theory as given in the article *LOGIC* are obtained from those of Zermelo by

Skolem's method, with addition of the axioms of replacement, due to Fraenkel, and the axioms of excluded infinite regress due to John von Neumann (later introduced independently also by Zermelo).

21. Richard.—Jules Richard published in 1905 the antinomy now known by his name. Semantical paradoxes related to Richard's were afterward proposed by various other authors, including the paradox of Kurt Grelling in 1908 (see SEMANTICS IN LOGIC).

22. Hilbert.—David Hilbert's contributions to logic arose from his work in the foundations of mathematics (see MATHEMATICS, FOUNDATIONS OF). Important among them are the program of proof theory and in particular of a metatheoretic consistency proof, dating from 1905, and in connection with this the sharp distinction between object language and meta-language (in Hilbert's terminology, between mathematics and metamathematics). *Grundlagen der Mathematik* (1934, 1939), a comprehensive treatise of modern logic containing Hilbert's ideas in their final form, was written in collaboration with Paul Bernays, to whom the detailed content of the work is largely due.

23. Brouwer.—Luitzen Egbertus Jan Brouwer is the founder of mathematical intuitionism (see MATHEMATICS, FOUNDATIONS OF; and THOUGHT, LAWS OF). His publications in this field began with his dissertation in 1907 and a paper on the law of excluded middle in 1908 and extended through 1954. The logistic formalization of intuitionism is, however, due to Arend Heyting (1930) and others.

24. Lewis.—Clarence Irving Lewis was led by the "paradoxes" of material implication (see LOGIC) to seek a notion of implication, *strict implication*, which shall correspond rather to the relation of logical consequence in the sense that, if $<$ is the sign of strict implication, and if A and B are any sentences, $A < B$ shall be true if and only if B is a logical consequence of A . Lewis's publications about the matter begin in 1912. But the first satisfactory formulation of a propositional calculus with strict implication was in 1920. The book of Lewis and C. H. Langford, *Symbolic Logic* (1932), treating the subject at length, has become a classic in the field of modal logic, and the starting point of many more recent investigations.

25. Loewenheim.—Leopold Loewenheim in a paper of 1915 proved the theorem which is now known as Loewenheim's theorem (see LOGIC), and several other important results in the metatheory of the functional calculus of first order.

26. Skolem.—Thoralf Skolem, besides the contribution to set theory already mentioned, gave a new and better proof of Loewenheim's theorem, established the extension of this theorem which is stated in the article LOGIC, contributed results connected with the decision problem of the functional calculus of first order (some of which were later important in the proof of Goedel's completeness theorem), and discovered also the following metatheorem, that no set of postulates, finite in number or enumerably infinite, expressible in the notation of a simple applied functional calculus of first order can be adequate for arithmetic in the sense of characterizing completely the system of non-negative integers.

27. Post.—Emil L. Post's dissertation of 1920, published in 1921, contains the first comprehensive metatheoretic treatment of a logistic formalization of the two-valued propositional calculus, including proofs of consistency and completeness; also the first formulation of a many-valued propositional calculus from a point of view which is abstract in the sense of being concerned with the form of the calculus independently of any particular interpretation.

28. Lukasiewicz.—Jan Lukasiewicz, in a paper of 1920, introduced a three-valued propositional calculus based on Aristotle's doctrine of future contingents (see THOUGHT, LAWS OF). This was later generalized to an analogous n -valued propositional calculus, different from that of Post. Much important work is also due to Lukasiewicz in the two-valued propositional calculus, and in the history of logic.

29. Tarski.—Alfred Tarski contributed extensively to two-valued and many-valued propositional calculus, taking his departure from the work of Lukasiewicz. However, his most noteworthy contributions, beginning in 1930, are to the general

metatheory of logistic systems, a domain in which many important new ideas are due to him. Especially semantics, in the sense of the metatheoretic treatment of notions related to those of meaning and truth, is the creation of Tarski (see SEMANTICS IN LOGIC). Much of the more recent work of Tarski has been in the boundary region between logic and mathematics, or has applied methods and results of modern logic to special branches of mathematics.

30. Carnap.—Rudolf Carnap, in his *Der logische Aufbau der Welt* (1928), *Testability and Meaning* (1936-37) and many other publications, was a pioneer in the systematic application of the methods of modern logic in epistemology and philosophy of science—making in this a contribution to philosophic method which in the eyes of many exceeds in importance his support of a particular philosophical outlook (that of logical positivism, *q.v.*). Carnap's contributions to the study of the metatheory of logistic systems begin in his *Logische Syntax der Sprache* (1934, published, 1937) in English with some additions as *The Logical Syntax of Language*. In a paper of 1935, somewhat later than Tarski but independently (and in a different terminology), Carnap introduced the idea of syntactical definitions of the semantical notions of truth and satisfaction, and in particular was the first to make such definitions for the full simple theory of types, as distinguished from a functional calculus of finite order. And concerning Carnap's contributions to intensional semantics, see SEMANTICS IN LOGIC.

31. Herbrand.—Jacques Herbrand in his short life—he was killed in a mountain-climbing accident in 1931 at the age of 23—made extensive contributions to Hilbertian proof theory and to the metatheory of the functional calculus of first order. The most important of these cannot be stated here. But the deduction theorem of first-order functional calculus should be mentioned as Herbrand's.

32. Goedel.—Kurt Goedel proved the completeness theorem of the pure functional calculus of first order (1930), and the famous incompleteness theorem (1931). For these, see LOGIC and (especially for the latter) MATHEMATICS, FOUNDATIONS OF.

The bearing of the incompleteness theorem on Hilbert's program of a metatheoretic consistency proof for mathematics is obvious; but more far-reaching is the consequence that no single logistic system, satisfying certain very general conditions, can tenably claim to embrace only logical truth and the whole of logical truth (if indeed the latter phrase has a meaning at all).

Also due to Goedel (1940) is the metatheorem that if the system of set theory with omission of the axiom of choice (see LOGIC) is consistent, it remains so upon addition of the axiom of choice or an axiom expressing the generalized continuum hypothesis or both. (For a statement of the continuum hypothesis see MATHEMATICS, FOUNDATIONS OF.) As Goedel pointed out, his result is applicable alike to various forms of set theory and to type theory.
